The frost of the 23rd, 24th, and 25th of May last has given us one useful lesson, from the fact that, except with the very late sorts, which were not then much in bloom, not one variety was injured more than another: of course, I am only speaking now as far as my own observation goes; but I saw many different gardens, both before and after the frost, and of course I saw them under a variety of circumstances, both skilfully and unskilfully cultivated. But in no instance did I see one variety injured more than another. As regards their cultivation, if ever I felt grateful for anything worldly, it is for the opportunities which a kind employer and a liberal editor have given me of seeing them under so great a variety of circumstances. I have seen many good gardens, as the readers of these pages already know, and I have seen the strawberries in some places, not noticed in my tour of inspection, where they have been literally killed by over-crowding and other varieties of bad management. I have heard the cultivator complaining of non-success when, if only the dictates of common sense had been followed up, success would have been certain. But so darkly stubborn are some men's minds against receiving the advice or adopting the practice of others, that they would rather go on for years in their old unsatisfactory track than condescend (!) to be benefited by adopting any method, good or bad, that did not originate with themselves.

How different is this from many other places which I have seen, where the directing mind is ever seeking to be benefited, not only by his own practice but by that of others! Under such men, I have seen the strawberry cultivated in a masterly manner, and from their free and expansive minds I have learned many useful hints as regards their management in peculiar soils or situations. Thus in one case I learn that it is necessary to make fresh plantations every third year, and that the ground, being light and porous, must be trenched to the depth of two feet, placing a good layer of rotten dung, twelve inches under the surface, to encourage the roots to go downwards, that they may not feel the effects of a severe drought. In another case I learnt that in cold stiff soils soot and lime are excellent spring dressings, and that treading upon such land during wet weather is fatal to the extension of the young roots in early summer; and also that a free and judicious use of the hoe, or a light fork, to frequently stir up the surface increases both the warmth and fertility of the soil, and that it is not desirable in such cold soils to put on anything with a view to keep the fruit clean until it becomes positively necessary, as it has a tendency to shut out the warmth which an uninterrupted exposure to the sun would give it. I learn too that early mulching with long dung, such as I am in the habit of using in early spring (or rather was in the habit of using), is found by others as well as myself to be best when put on about the middle of May instead of the early part of April, as if put on too early, say at the beginning of April, it encourages root action at the surface more than is desirable, and also prevents the sun from warming the soil as much as it would otherwise do.

Then as to the best crops, taking favourable and unfavourable soils together, there is no further doubt but that the more liberal the treatment the better the result; as, for instance, the distance of two feet apart each way from plant to plant is the most productive as regards narrow planting; but there are many, and I may say very many, positions where the crop would be still more productive at three feet apart each way, and this will apply with great force to strong deep loamy soils. If I wanted to convince any one of

* * * SUBSCRIBERS requiring back Numbers or Parts of the GARDENER'S MAGAZINE to complete sets, are requested to order them through their bookseller, who can always procure them from the London publisher. At the same time, instructions should be given that in some of the numbers required are out of print, as many as can be had should be sent, it being a rule with the book collectors, if they cannot obtain all the numbers wanted, not to take any, saying they are "out of print."

this, I should refer them to the gardens of Coombe House, near Croydon, where Mr. Page, an esteemed friend of mine, is gardener. The soil there is light, with a gravelly subsoil, and he plants at two feet six inches; and I will undertake to say that he has picked no less than three quarts of fruit from each *plant*, or could do so from a bed of Sir Charles Napier which I saw there early in June. But then he is one of those sensible cultivators who are in the habit of making observations, and he has learned what his soil will do and how to treat the plant upon it. Indeed, the condition of all his crops shows that he is not one of those haphazard unobserving men who has wasted a lifetime without receiving some benefit from experience. I wish I could say as much for the majority of British gardeners.

Apart from my own experience, which I have previously detailed in these pages, there is no doubt but it is a mistaken notion to suppose that we need to wait two years for a crop from a new plantation, as, if we are inclined to give the necessary time and means, a fair average crop can be secured the first year. But in the first place, if we have to purchase plants, they must be got early; that is to say, good strong plants must come to hand very early in August in good condition for planting. In the second place, the spot on which they are to be grown, to produce such early results, must be well and liberally prepared by deep trenching and by the addition of manure and fresh soil, if the old soil is at all exhausted. But when the cultivator can raise his own plants at home, he will do wisely to lay them in 4-inch pots the same as for forcing, and plant them out as soon as the pots are full of roots. I have practised this method myself, and with such varieties as the Empress Eugénie and the British Queen I have secured very good crops the first year, but of course better the second.

As to varieties most suitable to be grown, there are two things which must guide the cultivator in this matter. In the first place, the flavour of some sorts does not suit the taste of some individuals; as, for instance, the acid flavour of the Empress Eugénie and Trollope's Victoria is positively obnoxious to some, while by others these varieties are greatly appreciated. Then again some palates prefer the old Keen's Seedling, and in almost every instance the superior flavour of the British Queen takes first rank.

The next thing which ought to influence the gardener in his selection of sorts should be their adaptability to the soil of the place, as some will do much better than others in different soils. I know a good gardener at the present moment who is continually grieving because he cannot grow the British Queen in his light soil; but no efforts on his part will induce it to succeed. But for heavy loamy soils there are none to beat Keen's Seedling, Goliath, British Queen, Elton Pine, and Trollope's Victoria; while for light soils I should recommend Sir Charles Napier, Black Prince, the Princess of Wales, President, Eclipse, and Carolina Superba.

As regards the introduction of new varieties, it is astonishing how slow they make their way into public favour, and it is equally astonishing to the seekers after novelties how many of the old sorts still hold their ground. Look at the old Keen's Seedling, for instance; why I know of several noble lords who will have no other sort upon their tables, and see how it is still esteemed by nearly every forcer of early strawberries! This should act as a warning to young gardeners and inexperienced people not to speculate rashly, but in moderation and caution, in new varieties; although I do not mean to say but that some of the new kinds are in advance of the others, and I may instance particularly the *President* and *Premier*. These are both superb varieties for those who like a change, and are exceedingly useful for late forcing, as is also the *Princess of Wales*, for early work. But for myself I still cling to the opinion I gave in this work several years ago, that in a suitable soil I can undertake to supply a gentleman's table all the time strawberries are in season with the Black Prince as the first, the Keen's Seedling as second, and the British Queen as the third; and you will not find three better flavoured strawberries on the list: but the Black Prince *must be ripe*, not sent to table, as they usually are, not more than half ripe. To enjoy it in a legitimate manner, remember its name, *Black Prince*, and wait till it is black before you eat it.

J. C. CLARKE.

SUBSTITUTE FOR ASPARAGUS.—Mr. J. Ransley Tanton, in speaking before an audience at Croydon upon the productions of the vegetable kingdom, thus alludes to a British plant called Sea Holly. He says:—"Among the most useful farinaceous plants known in the vegetable kingdom, is one whose valuable properties appear but little known. The plant in question is the Sea Holly (*Eryngium maritimum*), a native of our own isle. This plant, when fully developed, measures 1½ to 2 feet high, bearing in July a conspicuous blue flower. Its roots are oblong, of a trailing habit, are sweet and aromatic. They are candied, and sold in the shops of Sweden under the name of Eriugo roots; but the chief feature possessed by this plant, and to which I wish to call especial attention, is that of its young shoots, which, if gathered in their early growth, when about 8 or 9 inches long, and cooked in the ordinary way, are superior in taste to and possess greater nutritious qualities than asparagus. I therefore think market gardeners may derive some profit by growing this plant for the purpose of forming boundaries, when its young shoots may be gathered and marketed for the purpose assigned.

MR. C. J. PERRY'S VERBENAS.

During my brief stay in Birmingham I went over to Castle Bromwich to see my friend C. J. Perry, Esq., and to make a few notes on his verbenas, as I might happen to find them at home. It is very well to see novelties at exhibitions, and in the majority of cases that is the only way in which we can see them. But when we go into a raiser's ground and see his stock, his specimens, his collections of other varieties besides his own, we can form a far better estimate of the value of his contributions to the classes in which he labours, than by the best he can do any day or every day at exhibitions. It is a delightful drive from Birmingham to Castle Bromwich, a distance of six or eight miles from the smoky town, through well cultivated and well timbered land, past a lovely common with scarps of gravel and sheets of furze, and blotches of picturesque brake and fine elm and oak trees—just such a ride as on the morrow of a day's hard work freshens one up for new rounds of duty, and gives one an appetite for such a bountiful and *recherché* luncheon as Mrs. Perry led me to with a genial welcome which is her own peculiarity. There I met my much-valued friends Mr. J. C. Ward, the landscape painter, who knows the value of indigo distances and fuzzy foregrounds better than any of us talkative gardeners, and Mr. William Dean, prince of florists and most catholic of horticulturists, of Bradford. They had come on the same errand, first to enjoy the social sunshine of Castle Bromwich, a spot exempted from the operation of the laws of eclipses, and is therefore independent of the Greenwich sages and the Nautical Almanac, for the sun is never obscured *there*; and they had come also to see the charming garden, with its leafy greenness one side and its tapestry of colour on the other. By way of acknowledgment, I shall take the liberty to say that our host and hostess secured us a happy hour, during which I am sure we all forgot our cares, and in a pleniudo of talk (and better things, including a dish of Wheeler's Tom Thumb lettuce, *true*), made sport of time and business, and journalism and each other! At last we turned out to see the garden, and once more I enjoyed the quiet lawn, with not a flower visible on or about its glad expanse of softest yet brightest green, but with beautiful coniferous trees dotted about at wide distances, showing all their noble characters, and in a state of health and beauty that cannot be surpassed by similar sized specimens in any garden in the land. And to place on record that in the garden of a man so widely known, and so highly esteemed for his skill and taste in floriculture, as Mr. Perry, a large space is set apart and separated from all the rest for verdure *pur et simple* is, I think, a matter of some public importance. If he were to cut this turf into scrolls, or sugar-plum it over with a geometric pattern in bright flowers, it would not have the charm it now has in its exquisite beauty and repose, its permanency of interest, or its true homeliness and quiet. Those three famous conifers, *Picea nobilis*, *P. Nordmanniana*, and *P. amabilis*, were here in the greatest beauty, though small specimens. Of Wellingtonias there are many, all of them models of symmetry. He called my attention to one as exemplifying how much gratification a man may derive from such things by observing their growth, and seeing them attain to the dimensions of timber, or something approximating thereto, a memorial of the planter's care and a record of his work, while at the same time, and increasingly so as time passes on, a standing reminder that our days are as the weaver's shuttle, and that a tree may outlive many generations of men. The tree to which my attention was directed was planted by himself, and when planted was just the thickness of his favourite rifle, which never misses fire, and is always well directed. It is now nearly as thick as his own body, and spreads its leafy branches on the ground in a splendid sweep, a great green tent with one pole that would give shelter from a most stormy blast. Good trees and good turf are the primal elements of a good garden; where neither are to be found, flowers are a mockery; they are like cake ornaments when there is no cake, or jewelry lost for want of a wearer.

The grandest feature in the way of flowers here is the compartment appropriated to roses on their own roots, pegged down. The ground is literally carpeted with roses, and the plants never become old; they renew themselves from the roots by means of fat shoots, that in their turn are pegged down like the long-rod system of grape growing, only we train the grape-rods up instead of fixing them to the soil. The glorious leafage of these roses would tell one without the help of flowers that they are in perfect health and tremendous vigour. I suppose that after St. Swithin many of these make shoots of six to eight feet in length, and that what has been said about the growth of the experimental own roots at Stoke Newington might need to be quietly suppressed if we were to institute severe comparisons. Mr. Perry makes no comparisons; I never met with a first-class cultivator who takes the whole affair so coolly as he does; he makes no boast of his work, and unless he had practical men constantly to visit him would perhaps scarcely know that what he does he does well—so well that we may travel far and wide to find its equal. In another part of the garden is a large compartment filled with dahlias, and this piece is enclosed with a square of brier roses, in beautiful health and flowering superbly. As Mr. Perry is an extensive and most successful exhibitor, it may be proper to state that he cuts from his standards and his dwarfs pretty equally, and that he scarcely practises disbudding, trusting rather to good growing for fine flowers than to excessive thinning. I forbear to enumerate the varieties met with, because the collection comprises all the best, and just now lists of roses occupy much room in our columns; and I will just add that in the lower part of the garden there is a great plantation of small Wellingtonias, set out in rows, nursery fashion, presenting a most beautiful appearance. And now we will go amongst the verbenas.

Mr. Perry is the best man in the country with these things, and especially in the breeding of varieties that make huge trusses, large, round, flat flowers of great substance and the most various and beautiful colours. It is true that verbenas, geraniums, petunias, and many other subjects are commonly judged as to their merits for hedging solely. It is a depraved taste that hedges in the judgment in such a case; but the fact remains, and we can only deplore, we cannot remedy it. The time will come perhaps when finely-formed flowers will be more generally appreciated, but the tremendous spell of the bedding mania has for the present paralysed the hands and blinded the eyes of many who should be ready to welcome intrinsic excellence in florists' flowers. But no matter; there are some who love them and understand them; and as diamonds and rubies are the property of the few, so the noblest flowers must be content with a limited circle of admirers. *Quality* is the characteristic of these verbenas. There may be, and doubtless there are, many first-rate bedders

amongst them; but Mr. Perry breeds for a class who, while not indifferent to colour, look for something more in a flower considered worthy of cultivation. The phlox-like concave pips of Madame Tonnelier; the enormous flat disks of Samuel Morton, glowing with rich shades of red and pink; the perfect outlines of Miss Turner, delicately tinged with rose on a bluish white ground; the majestic truss and deep compound of cobalt and indigo in William Dean, and the large circular rosy crimson flowers of James Birbeck,—are types of the superb strain Mr. Perry has originated by careful cross-breeding and judicious selection, carried on year by year in hope and confidence that practical truth would be found in the expression of the poet, "Nature never did betray the heart that loved her!" It need not be said that myriads of verbenas are grown to be destroyed. That is the case everywhere in the gardens of originators of new varieties; yet amongst the condemned, dozens, doubtless hundreds, of varieties may be found of a quality such as would tempt many a dealer to "send them out," confident that he was thereby adding to the joys of florists and the beauties of the world. The severe process of selection secures to the public from this source varieties of the highest character hitherto attained in this class of flowers; and when we went through the verberna houses wherein were the specimen plants of the selected kinds, we were astonished at the splendour of many that were doomed to be destroyed, but of course more astonished and intensely delighted with those set apart for our opinion, and for the interesting process of nomination, or, in other words, by us to be named. Mr. Dean had the lion's share in this task—and the lion's share is proper for a lion—for he went to Castle Bromwich over night direct from the rose-show dinner, and prepared by the fresh morning air of the lovely garden to do his spiring gently, and with the rare judgment that with him never fails. We had a thorough feast of comparing, admiring, and note-taking, being greatly helped therein by Mr. Ward, who is as sound a florist as he is a gifted painter,—and rather strange that, because as a rule painters abhor florists' flowers, and love the wild rose or the single pink better because of its picturesqueness than all the refined forms established by the florist. A spike of single hollyhock may look fine in a picture, especially if the subject be one that requires a cottage flower, but in a good garden it is another matter. Mr. Ward has the breadth of mind to compass both ideas, and it was delightful to have a painter assisting in the criticism, for usually we have these things too much to ourselves, and go all in a groove together like ants in a garden path. Here is the result of the floral congress, and its solemn decisions:—

PERRY'S SEEDLING VERBENAS TO BE SENT OUT IN SPRING, 1868.

Miss Turner.—White shading to bluish, with very large pale rose centre, very fine pip and truss.

Mrs. Mole.—Deep shaded lavender, large and finely formed pip, and beautiful truss.

Mrs. Perry.—Rich blue purple, with large light eye; very fine form.

G. P. Tye.—Lighter than Mrs. Turner, with a deeper coloured centre; a compact growing kind, with very fine pip and truss.

Interesting.—Pale scarlet, with distinct light eye; finely formed pip and truss.

Samuel Morton.—Shaded rosy bluish, with large dark centre; very fine pip and truss.

Emma Perry.—Bluish white, with large dark rosy red centre; very fine pip and truss.

Shirley Hibberd.—Intense dark violet, with small white eye; a rich looking flower of great substance and fine form.

John Wilson.—Rosy carmine, with a violet tinted centre; very fine truss and habit.

James Day.—Shaded light violet, with white eye; fine truss.

Little Clara.—Shaded pink, with dark carmine centre; fine form and fine truss.

Hercules.—Rich rosy carmine, with dark centre; very fine form.

James Birbeck.—Very large, rich, glowing light rosy scarlet deepening to crimson; light eye; extra fine.

J. C. Ward.—Light purple, with light eye; fine form and truss.

OLDER KINDS.

All marked thus * raised by Mr. Perry, and are fine exhibition flowers.

* *Delicata*.—Pale rosy pink, light eye, fine truss.

* *Indispensable*.—Shaded light purple; well formed truss.

* *Harry Law*.—Distinct rosy lilac, with large white eye; very fine pip and large truss.

* *William Dean*.—Rich violet, with darker centre and distinct clear white eye; finely formed pip and truss; extra fine.

* *Exquisita*.—Bright reddish pink, with large lemon eye; fine pip.

* *Snowball*.—The best exhibiting white, but not a pure white, and with a faint tinge of pink.

* *Nemesis (Smith)*.—Rich light scarlet, with small lemon eye; fine truss; fine for pots.

Annie (Cooley).—Dark pink striped.

Princess of Wales.—Light pink striped.

Marquis de Chateaubauf.—Purple striped.

* *Auricula*.—Rich shaded purple, with large light eye.

* *Firefly (Miller)*.—Lighter than Mazeppa; very fine pip and truss.

* *Leab*.—Pale shaded rose, with large dark centre and large white eye; very fine pip and truss.

* *Pink Perfection*.—Bright reddish pink, with light eye; a most valuable kind for pots or beds, also good for cut blooms.

* *Majolica*.—Shaded pale rose, with large white eye surrounded by a dark ring; very large pip and truss.

* *Wonderful*.—Shaded crimson, with white eye; extra fine in pip and truss.

* *Meteor*.—Rich glowing scarlet, with lemon eye; small but well formed truss.

Cato (Smith).—Bluish shaded and marked with pink, with dark eye; a good exhibition kind.

Rose Imperial (Boucharlet).—A glowing rosy pink, with large scarlet centre; very fine truss.

* *Mrs. Turner*.—Bluish shaded with pink, with a large deep rosy pink centre.

* *Mauve Queen*.—Shaded mauve and lilac, with large light eye; very distinct.

* *Cleopatra*.—Rich dark rose, with white eye; extra fine.

* *Charles Perry*.—Rosy lilac, with large dark centre and light eye; very fine truss and compact habit.

* *Champion*.—Rich crimson, with small dark centre and yellow eye, extra fine.

* *Mazeppa*.—Brilliant deep orange scarlet, with clear lemon eye; large pip and truss; extra fine.

* *Harry Turner*.—Shaded bluish and lavender, with a bright pink centre; very large well-shaped truss.

* *Novelty*.—A very fine kind when sent out three years since, but now beaten by Charles Turner.

Magnificans (Boucharlet).—Lilac shaded with pink, large dark centre; very large truss, and a fine back-row flower.

Apollo (Smith).—Bluish shaded with pink, with dark centre; very large truss.

* *Lilac Queen*.—Distinct from "Mauve Queen," and very distinctly marked; fine truss.

S. H.

PALMS FORM SEED.

SINCE my last notes on palms I have travelled far and wide, and have seen evidences of a fast increasing taste for plants of noble character. I am told that a great many palms and cycads have been sold in consequence of the few humble words I have said in their praise, and on the simple treatment they require. It is the common opinion, not in England only, but with all men, that, if they see some strange plant or animal, they conclude it requires a life-long-learned experience for the keeping of such, though the practical person could say that to keep a rare palm or a rare parrot, or even a bird of paradise, requires only such skill as may be soon acquired by those who have real taste in such matters. Of course I am well aware that there are some who are ambitious to do great things, and always fail because they have not the genius for the carrying out of the ambition with which they are fired.

Generally speaking, the unskilful kill their pets by doing too much. If we say, This plant requires much water, it is presently treated as an aquatic; and if we say, Keep it rather dry, they proceed to treat it as if perfection of cultivation consisted in baking it in an oven. I remember seeing a pet bird look very meagre, and refuse its food. I advised the lady to whom it belonged to give it a little hemp-seed. A fortnight afterwards she told me she had followed my advice, and her bird was dead. I asked a few questions, and soon learned that she had given the bird hemp-seed only, and it had got fat, and died through the disease of the heart, which is common to tame birds that become over-fat. Well, to apply this, I hope that the many amateurs who have read these papers, and have been purchasing palms, will bear in mind that there need be no excesses of heat or cold, or wet or dryness, in the cultivation of them. When we say they must have plenty of water, we do not mean that they should be drenched two or three times a day; and when we recommend shelter from sun and wind, we do not want them to be shut up in dark sheds and closets. I have just paid a visit to my friend the Editor, and have seen how simple is the culture of palms in one aspect of the case. He showed me plants of *Chamærops humilis*, *Latania Bourbonica*, *Chamærops excelsa*, and some others, that have been out of doors in a not very sheltered spot since the early part of April of the present year, and the growth of this season is quite satisfactory. I asked why they should be put out so early, and was very promptly answered, Because there was no room for them and many other good things under glass any longer; they must rough it, as several good ferns were doing that are generally kept under glass all the summer. I was told also that these very palms had been exposed to 8° of frost (Fahrenheit) in the past winter on one occasion, and were none the worse for it. So much for the idea that palms require to be coddled, as if unable to bear a breath of the common air. Of course, I am well aware—for has it not been my business to tend upon them in every stage of their history?—that palms from tropical regions must have heat; but I shall shortly give a list of hot palms that are worth particular attention, in the same way that not long ago I gave a list of palms adapted for cool treatment.* But, for the present, I will say a few words about raising palms from seed, for that is an amusement in which any amateur may most reasonably delight. As to procuring the seed, I can only say that I have purchased of Messrs. Carter and Co. large quantities of the seed of *Chamærops humilis*, for the purpose of growing small plants for the market, and I dare say, if I wanted other sorts, I should be able to get them either here or on the Continent. The seeds of palms preserve their vitality a long time, and therefore, wherever the seed is obtained, it is pretty sure to be good.

Take, then, the seeds of a palm; the stones taken out of ripe dates will do to begin with for experiment. If you have a good stove or forcing-pit, or any means of keeping the plants growing all the

* Mr. Prosper's list of Palms adapted for cool treatment will be found at page 5 of the present volume (January 5, 1867).

winter, sow the seeds whenever you can get them. But if you are in a small way, and must keep your young plants through the winter in a cool house only, just safe from frost, you must not sow the seeds till January. Then prepare a first-rate hotbed, or adopt such other means as will secure a heat of 80° for at least six weeks, and by the aid of this heat, with moisture, you are to germinate the seed. Now I know that there are many different ways of doing the same thing, but I shall tell you the best way for this business. If you put your seeds two inches deep in pans or pots, or in a bed of good leaf-mould or peat, and keep them always moist, and in a temperature of 80°, many will come up and make nice plants; but not all, for more or less will rot, and be heard of no more. But this is the usual way of proceeding, and I can tell the reader it is not the best way. By the plan I shall describe every seed that has vitality will germinate, and if we have much trouble to obtain the seed, we ought not to resort to means to kill it.

Now, then, make a bed of sufficient size. It may be made in a box, and the box may be placed on a tank or hoibed, but about all that use your own judgment. The bed should consist of the cleanest leaf-mould, not quite decayed. How shall I convey an idea of my meaning? Suppose, then, a heap of leaves has been laid by one year. When you turn it over, you find fine black mould and

together, with moss between them, on a tank or bed of the temperature of 80°, and twice a day give them a gentle fall of dew from the finest syringe, but beware not to make the soil more than a little moist; for the first fleshy roots they throw out do not appear to take up any nourishment until the nut out of which they spring is nearly decayed.

In a little time the rolled up issue from the nut will open on one side, and the character of a palm will appear, which is not the case at first. Then the little plants will require water at the root, and almost immediately you will find the young roots protruding through the holes in the pots. When this occurs transfer them to pots of 3 or 4 inches diameter, using a rougher kind of mixture, but composing the same ingredients as before. You must endeavour to get them into these larger pots without shaking the earth from their roots. As they are potted move them forward to a cooler place, and by degrees get them into the open air in a sheltered spot where the sun shines in the latter part of the day, and do not do much more to them until the next spring, when they will need to be transferred to pots of 5 inches, and may then have little tufts of peat of the size of walnuts mixed with the soil. About the wintering I need not say much: tender kinds must be kept warm; and the hardiest kinds, being small and unused to the

Davalliacanariensis.

Latania rubra. Areca rubra.

Cycas revoluta.

Rhapis flabelliformis.

Thrinax parviflora.

GROUP OF PALMS, &C., SKETCHED IN MR BURLEY'S NURSERY, BAYSWATER.

soft flakes of not quite rotted leaves, all mixed together; such is the soil to use. The bed should be one foot deep, or more, but not less, and should be made quite light, not pressed together at all, and with the most flaky part of the leaf at the top. Saturate this bed with water, and when it has become warm to the degree of 80 Fahrenheit, strew the seeds or nuts upon it, and then over them strew one inch depth of clean moss, or the well-known cocoa-nut fibre waste, using the most fibrous part of the waste for the purpose. Every day wet this covering of moss or fibre by means of the syringe, and let not the heat all go down, and in about twenty days the little plants will begin to spear through their covering, and from time to time, according to the species, every nut will germinate, not one will be lost.

It is the process of germinating alone that I wish to be carried on in this peculiar though most simple manner. When once the nuts have sprouted and are spearing through the covering, they must be drawn out with care, and every one be potted in a small pot, in soil consisting of equal parts of the finest leaf-mould, turfy peat chopped almost to dust, and bright silver sand. Take care to have the soil warm, and do not take the plants out of the house or pit to pot them, but have all the pots filled and taken in and placed on the bed, and then transfer the little plants from the malzdaare, or sprouting-bed, to the pots, and place the pots close

world, must have more care than old plants require. Of course I should say that the hot palms need not be taken into the open air at all, but may be kept growing at 70° without any rest at all during the first winter after raising them from seed.

The Editor has favoured me with a print of some palms from a sketch made in a London nursery. I am greatly obliged for the distinctive honour, as it may give interest to a story that I am sure must be dull to many readers. In the sketch I perceive *Latania rubra*, a most fast-growing majestic hot palm from Mauritius; the red margins of the leaves of this species are peculiar. *Areca rubra* I have never seen do well in cool treatment; it is a very handsome species. *Cycas revoluta* is not a palm, but nearly so, and a most fit associate; what splendour is there in this interesting plant! *Rhapis flabelliformis*: I am informed that this has flowered lately, under the skilful care of Mr. Burley; it is common to see it in flower in the open air in Italy and the south of France in the month of July, and I have no doubt that we might easily ripen the fruit of it. At all events, this is a cool palm, which I did not think of when making my list; and I think that in the Isle of Wight and southern Devon any species of *Rhapis* would live, like the *Chamærops*, in the open ground. *Thrinax parviflora* is a most elegant palm, which will bear cool treatment, and may be put out of doors in July and August.

KARL PROSPER.

THE SONG OF HOME.

How beautiful is Home! The wanderer sees,
 Returning from afar, the village spire,
 And the ancestral roof whose aged trees
 Shelter, perchance, wife, mother, child, and sire;
 Nor theirs the glory to which fools aspire—
 The empty bauble vainly called renown;
 They are content to light the evening fire,
 To feast on simple cheer, and lay them down
 In joyous rest to dream, unfearing fortune's frown.

How beautiful is Home, when Love adorns
 With splendours brighter than the morning sun,
 When it first gilds the silver Alpine horns,
 The village cot, the fair beloved one—
 Though poor in outward gifts excelled by none
 In all the finer feelings of the breast;
 How chime the hours to music as they run!
 Music of Love divine, that angels blest,
 Delighted, hied to hear from out their golden rest.

'Tis Love alone that gives to Home its bliss,
 Transfiguring common life with light divine;
 Love plants its Eden in the wilderness,
 Lights Heaven's own flame to gild the darksome time;
 In saddest breast, like diamond in the mine,
 Burns quenchlessly: and through life's inner night
 An orb of fairest grace and strength sublime,
 Pure as sweet Hesper set on Tempe's height,
 Streams prophesying Heaven, the land of Love's delight.

But Home in Heaven—a light within a light—
 A joy inspered in joy! How heauteous still
 The evening shadows when a new-born sight
 Changes to jewell'd fire the palace wall
 Of our divine abode; when over all
 A sky translucent, fire illumed, and fed,
 Expands sublime beyond the ethereal hall,
 Picturing o'er all its dome how angels wed,
 What marriage throngs sublime to heavenly nuptials tread!

THOMAS HARRIS, *Lyric of the Morning Land.*

Calendar.

WORK FOR WEEK COMMENCING JULY 20.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—During dry weather clear off exhausted crops of peas and beans, and dig the ground deep, and manure liberally. During showery weather plant out winter greens of all kinds. Be careful in transplanting not to bruise the leaves of the plants.

CELERY—Early planted out crops may now be earthed up, but do this when the plants are quite dry.

ENDIVE to be sown again, and strong plants in early seed-beds to be planted out.

SHALLOTS should be taken up as soon as the bulbs are ripe; if left in the ground, they will be injured by the autumnal rains. This remark applies especially to damp and low-lying soils.

SPINACH—Make ready a sufficient number of beds for the winter crop as soon as possible, in order to be ready to sow early in August. The soil should be rich, and the position chosen, if possible, should lie high and dry.

CAULIFLOWERS AND BROCCOLIS can be got out now on ground cleared of peas and beans. Trench deep, and mix the manure with the soil, so that it is evenly distributed throughout the mass.

ONIONS lifted may in a few days be taken up and laid in the sun to dry. If the weather is wet, spread them in a shed, or on some dry mats in spare frames. In some country places they finish off the onions for storing by placing them in a baker's oven after the bread is drawn. This is a very good plan, and a pretty certain remedy for hull-necks, and a green soft condition; but it is not likely any crops will require to be artificially ripened this season.

HOE VERSUS WATER-POT.—Hoing is one of the much neglected operations of which few have considered the value, and to keep down weeds is generally the sole object of using the hoe. Certainly that is a good object, and if these observations quicken the vigilance of gardeners who are a wee bit careless upon the growth of groundsel, couch, and bindweed, and other rampant weeds among their crops, it will serve one good purpose. But it must have frequently come under the notice of practical men that a piece of cabbage or cauliflower frequently hoed between, even to the extent of working the instrument very near their roots, always grow to finer proportions than similar breadths left to take care of themselves, with the ground trodden between to the hardness of a Babylonian brick, "to keep the moisture in and the heat out." In such a case it is made evident that there is a virtue in the hoe beyond the killing of weeds that rob away the nourishment required by the crop; and if the problem of their well-doing is to be solved by observation, it must be at daybreak, when every leaf is loaded with dew. Then it will be seen that ground recently hoed or pointed over with a small fork is uniformly moist, while hard ground adjoining the same plot is almost as dry as during the heat of a sunny day. The solution is simple enough. The rough open surface absorbs a large amount of dew, not simply because it is broken, but because it presents a greater extent of radiating surfaces, for the deposition of dew depends on the radiation of heat at the immediate surface, and the subsoil need not and will not be colder than the subsoil of hard ground, although it has a greater power of surface radiation. In fact, ground frequently hoed becomes warmer from its more ready absorption and conduction downwards of solar heat, so that the roots of the plants are kept warmer and moister in broken ground than in close hard ground, and therefore the vigorous

growth of vegetation is promoted by hoing. We have ourselves frequently indicated to gardeners that the chief benefit of dew to plants arose through its absorption by the soil for the nourishment of their roots. It comes to this, that if you cannot soak the ground with water, you have only to break the surface and it will soak itself. The more heat by day the more dew by night, the more cloudless the sky the heavier the deposition of moisture between sunset and sunrise. M. Duchartre's experiments show that if the dew is allowed to settle on the leaves of plants, and not on the soil in which their roots are, they gain nothing in weight, whereas when the dew is allowed to condense on the soil they gain considerably. A plant weighing 999.50 grammes was so placed that the soil in the pot had the full influence of the dew, and it had gained in weight when the dew was removed 13 grammes. Another weighing 1034.95 grammes gained 6.90 grammes. In other experiments where the soil in the pots was hermetically sealed, there was not only no gain of weight by dew, but a positive loss, which goes very far to prove that plants do not absorb much moisture by their leaf surfaces, and may perhaps give a new turn to our ideas on syringing. But let that pass; we will not throw away the syringe yet awhile. Plants with hard waxy leaves, such as *Veronica Lindleyana*, certainly do not absorb much, but they need to be kept clean; and plants with porous leaves, like the vine, do absorb largely, and may be kept alive for some time with the roots dried up, if the leaves are frequently wetted. But the hoing is the matter we wish our readers to think about and act upon. The hoe is an irrigator of as much value to the English gardener as the shadow is to the wretched cultivator of millet on the banks of the Zab or Tigris; and where people are wasting their strength in conveying hogsheads of water, which are often more harm than good, the labour might in most cases be saved, the ground kept clean at the same time, and the plants encouraged to push their roots about in search for nourishment, by the use of the hoe, and the hoe alone. Take notice of a rhubarb leaf; the midrib forms a depressed groove, and the leaf slopes up on each side of it, somewhat in the fashion of the two sides of a wooden water-shoot. The upper surface of the leaf-stalk is channelled too, and all night long the leaf distils dew from the atmosphere, the water trickles to the midrib, and thence finds its way by the channel of the stalk direct to the heart of the plant, for the benefit of its roots and rising leaves. This is the way nature makes almost every plant its own irrigator: we must co-operate with nature, and by the use of the hoe assist the soil also to drink freely of the dew of heaven, that we may enjoy thereby the fatness of the earth.

Flower Garden

ROSES may now be struck in any quantity to secure fine plants on their own roots. Make up a few frames—if with gentle bottom-heat, all the better, but that is not indispensable. There must be six inches of light rich soil in which to dibble the cuttings. Choose short half-ripe shoots for the purpose, and keep them shaded and frequently sprinkled.

BEDDING PLANTS.—Begin at once to make up lists of sorts likely to be required next year, in order to have time to propagate. Put in geranium cuttings in plenty; an open border suffices for them, but keep them regularly watered until they begin to make roots.

CLEMATISES FOR ARCHES, TRELLISES, &c.—Almost as long as man has taken pleasure in a garden has been considered climbers worthy of much trouble and attention, also why the trellises and arches, and numerous like contrivances, which exist in almost every garden? But how seldom are these well embellished! How often do we see worthless stuff running over such that never furnishes flower or fragrance sufficient to attract the attention of the most observant! It is not that good climbers are not to be obtained, but because a really good selection is but very rarely made. Lately, however, we have had such a telling addition to our stock in the way of noble hardy climbers, that we have only ourselves to blame if every wall and trellis is not sheathed with the highest beauty. *Clematis lanuginosa*, *C. azurea grandiflora*, and others, have long graced our gardens, and are remarkable for their enormous flowers of various shades of blue; but it is only within the past few years that numerous striking varieties of the family have been noticed at our shows, in various shades of blue and rich dark purple. They are so attractive in appearance and noble in flower, that doubtless many of our readers have been induced to purchase young plants, and therefore a few words on their culture may not be amiss. They are, when well grown and flowered, the noblest of all climbers for walls, trellises, or any other position in which hardy climbers may be desired. We have seen them flourish freely planted on the level ground, and allowed to stroll over it in their own way. On trellised arches which one occasionally sees in gardens, on the slender wire-work fence so often used of late, they are truly beautiful and effective. They, like most things that we have to treat of, enjoy a good rich soil, and if with that it is light and free so much the better. If the soil is very heavy, it had better be made light by the admixture of road-sand, leaf-mould, and other matters which may be convenient before planting; if light, it must be well deepened and enriched with rotten manure, and stiffish loam, if convenient; but, no matter what the soil may be, the secret of cultivating these clematisses is to give them a few inches of well-rotted manure on the surface of the earth all round where the roots are, or, in other words, to "mulch" them. If the appearance of the manure is objected to, as it may be by many, it may be covered with an inch of soil, and on that some annual, like the aster, may be grown for the summer months. As regards training, they are best left alone in summer, at least till the shoots got very long indeed; but during the winter months they must be firmly tied or nailed over whatever surface they occupy, as the weight of flowers is considerable where they are properly grown, and by having the main shoots firmly secured, the rich mass of blooms, many of them as large and larger than tea-saucers, may be allowed to hang down in a graceful and natural manner, which much increases the beauty of the plants and whatever position they adorn. It is almost useless to enumerate any special kinds among those new hybrids and varieties sent out by Messrs. Jackman, as all are good, and it is only necessary to pick out the most diverse, and in many gardens where climbers are much valued all the varieties will be acceptable. Within twenty yards of the spot where we write this there is a splendid plant of *Jackmannii*, every shoot suspending a range of noble rich violet flowers, and several dozen other kinds, large and small, and all nearly equally beautiful and equally appreciated. The small kinds—like *Viorna*, with its pale pink flowers; *Shillingii*, with its very delicate ones; *Flammula*, with its mass of fragrant spray—cover arches beautifully, and look effective in the mass; while here and there the splendid single flowers of such kinds as *Rubro violacea* catch the eyes of many who hardly ever notice a flower. Those who plant clematisses should never by any chance omit the beautiful

large-flowered variety of *Clematis montana*, usually called *C. montana grandiflora*, as its beauty in the early part of the year, before any of the other kinds expand, is unsurpassed by that of any other hardy or tender climber. *Clematis*s purchased now in pots, and planted at once, will become established before winter, and make a fine display next season.

SHRUBBY VERONICAS.—This being the best season in the whole year for propagating these shrubs, a few remarks upon them may be useful. When well grown they are massive in outline, and their handsome dark green leaves afford a fine relief to the colours of their flowers, which are abundantly produced, and are always pleasing. Among the reasons that present themselves in recommending these plants to the more favourable notice of amateurs are the following:—They are, in the first instance, highly ornamental, and well adapted for greenhouse and conservatory decoration, and for plunging out of doors, where in the autumn they appear to great advantage, if the plants are large and skilfully grouped. They are so nearly hardy that the protection of an unheated greenhouse is quite sufficient to carry them through the winter safely. They do not quickly suffer from neglect; if rather dry at the root, or if watered to excess, there is not the immediate or extensive mischief produced which would occur in the case of many other favourites, but, of course, every kind of ill-treatment is an injury to veronicas, and they deserve good treatment. Lastly, they do not appear to suffer from dust, smoke, and atmospheric impurities, so that they are good town flowers, and in every sense well adapted for those amateur cultivators who are often away from home, and consequently unable to afford to plants of delicate habit the regular and careful attention they require. The shrubby veronicas can be grown in various ways, as may be determined by the wants of the cultivator. They are sometimes planted against dwarf walls, and in sheltered places do not greatly suffer from the frosts of winter. The writer has seen in a garden in Hants a dividing fence formed of *V. Andersoni*, which presented a remarkable and most beautiful appearance at all seasons, and especially when in flower. For ordinary decorative purposes pot specimens have the best effect when formed into regular pyramids with an even distribution of furniture from top to bottom. A good specimen should measure four feet in height from the rim of the pot, and four feet through at the base, tapering thence regularly to the summit. When grown for plunging out of doors to form autumn groups, a columnar style of training will be the best, or say an outline approximating to a Lombardy poplar, as this allows of placing the plants close together, and a better effect is produced than by plunging specimens broad at the base. To grow fine specimens, the soil should be good turfy loam enriched with a third part of decomposed hotbed manure, and with an admixture of broken crocks or bricks to keep the soil open. The young plant should be trained perfectly straight so as to secure a strong leader, from which in subsequent growth a regular disposition of side branches will proceed. From April to August the plants are to be shifted to larger and larger pots as they require them; they ought never to be thoroughly pot-bound until they have attained their full size, and are wanted to flower finely; but, on the other hand, each shift should be slight, as over potting at any stage is nearly as bad as allowing them to become pot-bound. After the middle of August there should be no more repotting, but in the month of April all the specimens should be turned out of their pots, the balls reduced, and much of the old soil be removed, and repotted again either into the same or into pots one size larger. As in the spring they do not evince much activity of growth, they may be pruned back when repotted. This should be done in a way to cause a regular disposition of shoots according to the form required, and as they break freely from old shoots and from the stem, ugly specimens may be pruned very severely, and if kept shaded and frequently syringed, with only a little water at the root, will soon throw out abundance of shoots, which the cultivator can keep or remove as may be needful. At the beginning of June all fast-growing plants which it is desired to form into compact specimens should be stopped; that is, the points of the shoots should be pinched out; this will cause them to produce side shoots, and there will be ample time for these side shoots to be fully matured before the close of the season. The following varieties are the best in cultivation:—*Andersoni*, grows freely and flowers abundantly; the variegated-leaved variety of *Andersoni* is extremely beautiful, and more tender than the green-leaved kind. *Anne de Beaujeu*, bright rose and white; *Devoniana cœrulea multiflora*, dark violet and white; *Gloire de Loraine*, blue and white, beautiful habit, and remarkably hardy, for a plant of this stood out at Steke Newington all through the winter of 1866-7, and was quite unhurt; *Impératrice Eugénie*, amaranth; *Mammoth*, violet and white; *Multiflora*, dark violet and white; *Rubra elegantissima*, violet purple; *Rubra splendida*, rich crimson.

Fruit Garden and Orchard House.

STRAWBERRIES to be potted as soon as rooted, as they make roots faster in pots than in the open ground; and should we have a chilly autumn, a few of the best of the plants can be kept under glass to ripen their crowns. Lay a few more of the best runners in pots, cut away all weak runners, and supply water liberally to runners and old stools.

Greenhouse and Conservatory.

CONSERVATORY will now need a revision, and a general change of occupants. *Liliums* and *Gladioli* will now come in, and make a fine show with first-class annuals and *Fuchsias*. Specimen trees and climbers to be stopped and trained in, to assist ripening of the wood.

HERBACEOUS CALCEOLARIAS.—Sow the seed without loss of time, using light rich soil. Place the pans in a cold frame, and keep shaded.

SAVING SEED.—Many choice border plants are now ripening their seeds, and whatever is required must be secured in time. Generally it is safest to gather the seed before it is dead ripe, as in many cases the pods open and the seed is scattered and lost. Cut off bunches with a portion of stem attached, and spread them on cloths, under cover, to dry for a day or two, and then put them in the full sun to harden. A shelf in a greenhouse is the best place, because there is less fear of their being scattered by wind. Label all seeds when gathered, to prevent mistakes, and of all hardy subjects sow a portion at once, and keep the rest till spring.

CLIMBING FERNS AND LYCOPODIUMS.—The climbing ferns of the genus *Lygodium* are the loveliest of the whole of this interesting tribe of plants, only excepting the elegant *Gleichenias*. It happens most fortunately that they are very easily cultivated, and, with moderate care, soon make fine specimens. We have had *Lygodium scandens* in a vase covered with a glass lantern, one side of which is completely covered with a screen of its exquisitely beautiful fronds, by being trained up on copper wires; and we have had *L. palmatum* on the back wall of a common greenhouse, where it was kept constantly shaded

by large-leaved plants trained to the rafters, and it covered the wall almost as densely as ivy. A mixture of two parts turfy peat to one part each of rotten cocoa-nut dust, and silver-sand, will grow any of them to perfection, with moderate warmth, shade, and moisture. *L. palmatum* is the most hardy; *L. japonicum* does well in a Wardian case, if assisted with copper wires; *L. venustum* is a very rapid grower in a warm greenhouse; *L. scandens* has the most distinct character; *L. flexuosum* is the grandest of all, and will grow five or six feet high; and *L. volubile* makes a good companion for it. Warm greenhouses in shady positions may easily have their walls covered with these ferns by making a border for them one foot deep and one foot wide, with three inches of broken brick or stone at the bottom and nine inches of soil. The surface of the bed may be covered with *Selaginella apodum*, *caesium*, *denticulatum*, *microphyllum*, *densum*, *brasilienis*, and *uliginosa*. *S. levigata* is a grand stove climber. *Lygodium*s should be cut down to the ground in winter. This is a most important point in their cultivation.

Stove and Orchid House.

STOVE AND ORCHID HOUSE.—Sun-heat may be used to prevent need of fire to a great extent. There must be plenty of moisture in the atmosphere, produced by frequent sprinkling of the paths, stages, &c. *Stanhopeas* will require to be repotted as soon as they have done flowering, if they require it at all, but fine specimens can only be obtained by allowing them to remain several years in the same pots or baskets. Give air freely, especially to subjects going to rest.

APPELELIXIS, PIMELIAS, IXORAS, &c., now going out of bloom to be cut back freely and put in a shady place, where sprinkle their tops frequently, and keep their roots rather dry till they break, when to be repotted. In repotting use the compost rough and lumpy for all except young plants.

Forcing Pit.

PEACHES ripening off to be kept as cool as possible; hot sunshine and close air will spoil the flavour and cause the fruit to fall. Where the supply is larger than can be used directly, the fruit may be kept hanging longer by shading it with leaves; a few boughs of privet or fir hung up so as to screen off the sun from the branches on which the fruit hangs, and free ventilation day and night, will retard the final ripening, and prolong the season of supply. Trees from which the whole crop has been gathered to be liberally watered and syringed, to keep the foliage fresh till it has done its work.

PINES to be encouraged with a good heat and plenty of moisture. Those swelling fruit to have the help of a humid atmosphere by watering the paths and the surface of the tan, &c., amongst the plants till the fruit begins to change colour, then keep the atmosphere rather dry. Young stock to have air cautiously; the suckers rising from old stools to be earthed up, and have a brisk heat and plenty of water.

VINES.—Late grapes require no artificial heat to ripen them properly, as the sun-heat is above the average of the season. If the ripening is long about, the berries will have thick tough skins, and will not keep well. Keep the houses dry where grapes are hanging, and those from which the crop has been gathered take off the lights.

MELONS need a brisk bottom-heat to ripen the fruit, and to be kept rather dry. Those swelling fruit to be encouraged with a lining, and a moderate amount of atmospheric moisture. Keep the vines regularly trained, so that the leaves are exposed to light, as wherever they are crowded the fruit will be found to damp off.

Correspondence.

CALCEOLARIAS IN 1867.—As I was walking over Highbury Hill a few days since, and pondering some remarks of yours upon the calceolaria in your impression of July 6th, it occurred to me that cultivators of the calceolaria would do well to bear in mind that its native habitat is a position not very far beneath the snow-line on the mountains of central South America, where, while they are constantly saturated with water from the melting snow, in that bright climate rain never or seldom falls upon the foliage. I believe great numbers of calceolarias are lost by watering over the foliage. The constitution of the leaves is so tender that the rays of the sun, brought to a focus in the multitudinous drops of water covering the plant, concentrate upon it a larger amount of heat than it can bear, and it suddenly perishes. I have seen but few examples of disease in calceolarias this year, and those only in one place. A neighbour had a two-light frame full in 60-sized pots, and during the bright hot week we had in the early part of May about thirty of them went off suddenly without any apparent reason. Since reading your remarks, I have thought that the action of the sun upon the leaves while wet must have been the cause of death in this case, because the plants were standing in a position where the bright rays of the afternoon sun would be concentrated upon them till near sunset; and if they were watered early in the afternoon, which I think they were, that fact might account for their sudden decease. The finest clump of calceolarias I have ever seen was in a garden on the north side of Stamford Hill. In this garden there was a piece of standing water all across the bottom, and kept pretty much to one level, and the water from this pond infiltrated through the banks, and stood at the same level over the whole garden, about twelve inches from the surface. In a bed on the lawn, about forty or fifty feet from the pond, calceolarias were planted; as soon as they had got hold of the soil, and began to feel the benefit of the water at the bottom, their progress was marvellous, and the vigorous panicles and rich colouring of the flowers indicated their thorough appreciation of the position in which they were placed. These, as near as could be, were placed in a position resembling their native habitat, with this difference, that the water in the bottom of the clump in the garden was stagnant, or at least was not supplied so continuously as that supplied to those growing on the mountain sides, which drains away from beneath the plants as fast as it is supplied from above. The débris and alluvium brought down by the continually running water will be likewise a constant stimulus to their growth. I believe few losses would occur among this class of plants if your suggestions were attended to. In addition to thorough preparation of the soil, copious waterings among the plants without wetting the foliage, and occasional top-dressings of soil similar to that in which the plants are growing, will exactly meet the requirements of this most effective plant.

WILLIAM CHITTY.

Stamford Hill, July 13, 1867.

NEW PLANTS FROM EQUATORIAL AFRICA.—As I might be too trouble-

some by giving full details of my new plants through the medium of your now crowded paper, therefore, in answer to numerous applicants, I am publishing a small work giving a full and complete history of the place from whence the seeds were brought, the method of cultivating in this country as adopted by myself, with diagrams showing the plant in three stages, hoping by this to benefit all. I can accommodate a much greater number than have yet applied for seeds when they are ready, say a week or more, but cannot take upon myself the cost of postage. I name this because the greater number arrive unstamped. Nor was it possible for me to write a guide until so many questions were asked me. Those who have sent stamps will be furnished with seeds as early as possible. Should more of your numerous readers require seeds, hooks, &c., I shall charge 1s. 6d. for cost of same, as I am only a working man, and taking into consideration I have the plants thirty-three miles from my present residence, I have already spent much. In conclusion, Mr. Editor, Mr. Hullett, and the Editor of the *Mechanic and Mirror of Science*, and your respected self, shall have plants as early as convenient.—I am, sir, respectfully,

A. St. Hilda Street, Hartlepool.

J. HESELTON.

[It is extremely kind of our correspondent to make us a promise of a plant, but we are not at all flattered by being associated with Mr. Hullett; and now that we hear of a hook to be published, &c., &c., &c., &c., &c., we think it proper to tell our readers that if they part with their money for hook, seeds, or what else, it must be upon their own responsibility and not on ours. We inserted the first letter in full faith, believing Mr. Heselton had got hold of something out of the common way, though it might be a plant well known to horticulturists. We insert this second letter in order to express our belief that he has got more than he can manage, for the number of persons who will buy books about unknown plants and seeds that have no name are very few indeed. Mr. Heselton had better go on with his carpentering, or whatever else may be his business, and leave the seed trade to those who understand it.]

Mrs. PINCE'S BLACK MUSCAT GRAPE.—I am preparing to plant a number of vines this autumn, and I want to know in sufficient time what is the opinion of grape growers generally in respect of this variety. I think it proper to say that I accept the good character our Editor has given it as sufficient in respect of its goodness, and to the exact extent to which he has committed himself to it. For many years past I have never sent an order to a nurseryman without consulting the lists in the "Garden Oracle," and generally speaking my selections of varieties, especially for exhibition purposes, have been taken from that work. I say this much to clear myself of all suspicion of unpoliteness in asking for more information respecting this grape than has been afforded us through the pages of the Magazine. Is it quite distinct in habit and fruit? Is it of a good constitution, or must we grow it a few years and then discover that it must be grafted on a free stock to make it fruitful? In short, granting that it is good because we cannot question the very high testimony in its favour, is it desirable that in planting a house of vines in a garden where grapes are grown largely, Mrs. Pince's Muscat should be considered essential? Probably some of your West of England correspondents who have seen the variety more than once can tell us something more about it.

R. W. P.

TEA ROSES AT EXHIBITIONS.—I was at once convinced of the soundness of your criticism on the showing of tea roses in classes by quietly making up a box of teas for our local show a few days since. I put together a magnificent lot of flowers, and, as you say, they looked tame, and it was a disparagement to their beauty to show them side by side without proper relief. As I was not tied by a schedule, but was going in for an extra, I fitted up three boxes instead of one, using high-coloured roses, such as Charles Lefebvre, Victor Verdier, Xavier Oliho, &c., &c., with teas intermixed. The effect was charming. A *Devoniensis* or *Homer* seated in the midst of three or four crimson, rose coloured, and purple flowers, is something to see, and we cannot fail to see it, but the same two roses side by side are agreeable only to the rosarian, who looks at the make and shape of single flowers, and not to the effect of grouping. It is easy to overdo a good idea, and when we have special classes for teas, mosses, &c., &c., I fancy the idea of a rose show is overdone.

SUB ROSA.

New Plants.

In the June and July Nos. of the *Botanical Magazine* occur figures and descriptions of the following:—

Amaryllis pardina.—A splendid species, obtained by Messrs. Veitch, through their collector, Mr. Pearce. It is a native of Peru. The flowers are of large size; the colour gamboge-yellow, covered all over with small red spots.

Bletia Sherrattiana.—The prettiest of the true *Bletias*, a native of New Granada. The flowers are produced in clusters of a dozen or more; they are of a purplish rose colour.

Billbergia sphaacolata.—A handsome Bromeliaceous plant, conspicuous for its crown of leaves, each from four to five feet long; the flowers are rose colour.

Stemonacanthus Pearcei.—A fine Acanthaceous shrub, with ovate lanceolate leaves five to six inches long, and axillary clusters of scarlet flowers.

Dendrobium macrophyllum var. *Veitchianum*, described as the true *D. macrophyllum* of A. Richard.

Draba violacea.—A pretty species of this generally humble genus. It is a native of the loftiest parts of the Andes to which any flowering plant attains. It is of neat shrubby habit, with terminal clusters of crimson-purple flowers.

Ipomœa Gerrardi.—This is the "wild cotton" of Natal. It is a fine perennial species of *Ipomœa*, requiring intermediate or stove heat; the flowers are large, salver shaped, pure white.

Rudgea macrophylla.—A magnificent stov shrub from Rio de Janeiro, which flowered in Messrs. A. Henderson's nursery in March of this year. The leaves are obovate oblong, one to two feet in length; the flowers are cylindrical, cream-white, and collected into a globose head as large as a fist.

Epidendrum Cooperianum.—This is one of the finest of *Epidendrums*. It is a Brazilian plant, and grows readily in the Cattleya house. The flowers are produced in a short crowded raceme; sepals and petals yellowish brown, the lip bright rose.

Gloxinia hypocyrtiflora.—A beautiful species, with cordate leaves of a brilliant green, distinctly marked with yellowish or whitish veins; the flowers are the size of a small cherry, brilliant orange and orange-red.

Replies to Queries.

Wall Fruit in Yorkshire.—Perseverantia.—The forty yards of wall you propose to build will accommodate six trees, large, at 20 feet apart, and five small trees in the mid-distances between them. These last will have to be removed when the permanent trees have made some progress. The following varieties are recommended for the permanent furnishing of this wall: *Hemskirk Apricot*, *Downton Nectarine*, *Sulhamstead Peach*, *Denniston's Superb*, *Guthrie's Green Gage*, and *Diamond Plums*. For five dwarf trees to plant in the intervals we should recommend *Morello* and *May Duke Cherries*, *Mirabelle Plum*, *Pitmaston Nectarine*, *Roman Nectarine*. We should prefer a 15-foot hollow wall to a flued wall. Of late years cheap glass has put flued walls out of favour, and they have never been of much value. The hollow wall (*Silverlock's system*) is warmer and drier than a wall made in the ordinary way, and costs considerably less in the first instance; so there are positive advantages in adopting it. The *Sylvester system* requires the wall to be 9 inches thick, with piers of 14 inches thick at every 20 feet. The wall and piers are all built brick-on-edge, with good mortar and the best work. The bricks are laid with their faces and ends alternating, which gives immense strength to the construction, and encloses within the work an immense body of air. There are many grave objections to flued walls, such as the following: In calm mild weather much of the heat is lost by the exposure of the wall to the atmosphere, and wind and rain sweep away the heat so fast that there is a great consumption of fuel for a very precarious result. In the event of a sudden blast of cold weather—a not uncommon occurrence—after the fires have been put out for the season, the trees suffer more than if they had never had help at all. On the other hand, hot walls have in many cases proved of great value in spring to assist the early growth and bloom, and in autumn to promote ripening of the wood, but for promoting the maturation of the fruit they are of no use at all.

Roses in Yorkshire.—Yorks.—The following climbing roses of good quality are likely to do well on a good wall in your climate: *Devoniensis*, *Lamarque*, *Gloire de Dijon*, *Triomphe de Rennes*, *Souvenir de la Malmaison*, and any of the vigorous growing hybrid perpetuals.

W. D., Lenoxtown.—The gentleman to whom you refer does not sell, and would not sell under any circumstances, except perhaps in the event of a large offer for the whole collection.

Datura ceratocaulon.—Wylde Green.—Probably in a brisk heat the seed would have germinated. These seeds keep good many years; therefore we do not think you had had seed. As for the *Everlasting Pea*, the best way to deal with that is to sow it on a sheltered border, and leave it alone. If you have any of the seed left, sow it now an inch deep, and wait. Next time you try the *Datura*, sow it early on a good hotbed, and get the plants forward, so as to be planted out strong at the end of May, unless to be flowered in pots.

G. W. M.—Pay no attention to the nonsense they tell you about the thickness of the parent stem, and all that. Just go on growing your vines in a reasonable manner, and you will have a reasonable return in the shape of fruit.

Pit for Compost.—T. P., Marylebone Road.—Form the pit of brickwork in a quite dry place under cover. If exposed to the weather or to the drainage of water, the best of compost is soon spoiled. Do not go mixing manure, ashes, soapsuds, &c., &c., but get good rotten dung, sweet turfy mellow loam, clean sand, and he content. Amateurs unaccustomed to the practical work of gardening *in extenso* make dreadful mistakes in compounding composts, and then think it hard their plants should perish. If they would be content with wholesome and unmistakable ingredients for their composts, they would have no trouble.

J. Thomas.—The variegated-leaved *Heliotrope* is extremely pretty, the young leaves being of a creamy amber colour, and the older leaves freely blotched and splashed with white or gray. We are informed by Mr. Salter that several variegated *heliotropes* have been tried, and never proved of any use.

Lapageria rosea.—F. L.—This beautiful plant requires a cool, light, airy house, a bed of gritty peat, and an abundant supply of water. In these few words you have an entire code of culture. Many have attempted to grow this plant in pots, but with very small success; others have attempted to force it with heat, and have failed, but the simple cool culture we recommend never fails, and whoever can spare a few square yards of the roof of a cool house, and make a peat-bed large enough to hold two or three harrow-loads of soil, may grow it to perfection. In the *GARDENER'S MAGAZINE* of December 1, 1862, will be found a concise treatise on the cultivation of this fine plant.

Asparagus Bed.—George.—A well-made asparagus bed will last a lifetime if taken proper care of. It is a good plan to remove the seed while green, as it prevents the growth of seedling plants between the rows, and which only makes work to weed them out.

Winter Flowers and Plunging Plants.—George.—For the greenhouse and conservatory secure plenty of *Cinerarias*, *Cyclamens*, *Acacia grandis*, *Gauntlet Pelargoniums*, *Echeveria secunda*, *Tree Carnations*, *Cytisus Atleena* and *racemosa*, *Daphne indica odora*, and *Czar Violets*. For the border which requires plunging plants to follow hyacinths, secure a sufficient number of potted plants of *Alyssum saxatile compactum*, *Iberis sempervirens*, *Dielytra spectabilis*, *Aubretia purpurea*, *Saxifraga hypnoides*, *Golden-tipped Stonecrop*, *Ranunculus ficaria*, and look after *Anemone fulgens*, with a view to get up a stock from seed, should you ever obtain a plant to begin with.

Budding on the Briar.—C. H. B.—In such weather as we had all the past week, hudding was profitable work where the briars were fit for it. We always prefer young thin briars for special purposes, but serviceable trees may be made out of briars of any kind; the grand thing is to grow them liberally in every respect. Your friend will make better progress by seeing the operation once performed than by all the book teaching available. All these matters are treated in full in the "Rose Book;" we cannot enter into them largely now, having done so in 1864. The original name of *Celine Forester* was *Lysias*. The beautiful *Noisotte Triomphe de Rennes* flowers finely at Stoke Newington, so we presume it may be considered a town rose.

SUBSCRIBERS TO THE *GARDENER'S MAGAZINE* who desire to extend its sphere of usefulness, and are willing to interest themselves in promoting its still wider circulation, can materially further this object by sending to the publisher the names and addresses of persons they think are likely to become subscribers, who will forward to each a SPECIMEN COPY free. A stamp must accompany each name and address sent, to cover the postage of the specimen copy.

The Gardener's Magazine.

SATURDAY, JULY 27, 1867.

FASCIATION AND HYPERTROPHY, though properly regarded by physiologists as forms of disease, produce results which the horticulturist accepts as adding to the variety and interest of cultivated plants. Arboriculturists are familiar with the bunched bird-nest kind of growths so common on the birch and fir, and which are usually attributed to the development of "accessory buds;" these becoming more or less united, assume a thickened or flattened process. In other cases unions of stems take place, and there are everywhere to be found examples of fasciated *Asparagus*, *Celosia*, and *Ranunculus bulbosus*. Less common than these are fasciated forms of *Hieracium cerinthoides* and *Carduus palustris*. We once walked for miles along a country road which was flanked on both sides by a continuous line of common Thistles, all of which had fasciated stems and flower-heads, a most remarkable mass of monsters. We have at the present time in the trial ground at Stoke Newington a variety of garden Pea with a fasciated stem as broad as three fingers, consisting of some half-dozen or more stems

THE INDIA HOUSE BALL.—In Mr. Digby Wyatt's account of the India House ball, speaking of the floral decorations, he says, "We were favoured by the authorities of the national gardens at Kew, under the personal superintendence of the curator of those gardens, Mr. Smith, with many beautiful and very valuable plants; and by the Horticultural Society, through the kind assistance of Mr. Eyles, with a precious van-load from their London conservatories; but the real onus of the supply rested on the broad shoulders of Messrs. Veitch and Sons, of King's Road, Chelsea. The formation and equipment of the beautiful cascades and fountains, the parterres and flower baskets, the waving groves of exotics, and the vases of bloom which met the eye almost wherever it turned, were due to them; and it is not too much to say that they never left off work from the time they received the order to prepare to the moment when the first visitor entered the ball-room."

THE LAST EXHIBITION OF THE MANCHESTER BOTANICAL SOCIETY for the year 1867 will take place at Old Trafford, in close proximity to the grand show of the Manchester and Liverpool Agricultural Society, August 27th to 31st. The Council of the Manchester Botanic Society have resolved to hold a great show during the Whitsun week of 1868, and have already obtained a sufficient guarantee in respect of the risk to be incurred. The sum at present voted for prizes is £1,000, which may possibly be added to ere the schedule is issued. It is to be hoped that no other society capable of competing with this will fix upon the same date for a great exhibition next year, for such competition is simply vexatious, and more or less injurious to both parties. The Manchester folks have announced their intention in good time, so there is really no excuse for the damage of their project by the selection of the same date by any other powerful corporation.

17 inches.

SEDUM VIRESCENS, COCKSCORN FORM.

united, and with all the branches and tendrils of those stems radiating from the summit in a regular manner, like the ribs of an umbrella. Lord Wellington Hyacinth is peculiarly liable to produce compound spikes of flowers proceeding from two or three stems united in one, and showing by deep furrow-like sutures where the junction can be traced.

A few months ago we obtained from Mr. Ware, of the Hale Farm Nurseries, Tottenham, a fasciated form of *Sedum virescens*, which very soon afterwards attained to unusual dimensions, and a beauty quite remarkable for an abnormal development. We present our readers with a figure of the plant, which, at the time it was sketched, measured exactly seventeen inches between the two extreme points of its cockscorn head. If all the convolutions had been measured, the full linear breadth of the head would have been about thirty-five to forty inches, so densely was it frilled on the margin. The leafage was abundant, but contracted into tooth-like processes, which added to its beauty and enhanced its frill-like peculiarity. In the figure, a few sprigs of natural growth may be seen on the right hand of the central lobe of the cockscorn. *Sedum virescens* (in common with other small-leaved Sedums) frequently presents itself in a fasciated form, but the example before us is remarkable for its size, symmetry, and extravagant convolutions.

No. 117, NEW SERIES.—VOL. X:

THE HARVEST has become general in Hungary, and in the southern provinces of the empire, and promises to be magnificent. The weather is exceedingly favourable. The *Triester Zeitung* states that during the last few days considerable orders for grain had arrived from England, and the agents sent by the corn merchants to Hungary in consequence had already bought up more than two millions of metzen—nearly four million bushels. The French have been making large purchases, chiefly in Hungary, for some time past.

Mr. G. HORNE, Assistant-Director of the Botanical Gardens in the Mauritius, has sent in a very interesting report of his visit to Ceylon, in which he has given a practical description of the cultivation of Cinchona, Coffee, and Tea, likely to be very useful in the colonies. This report has been published in the *Government Gazette*, and an abridgment will be found in another part of the present issue. It is only one of the many proofs this intelligent officer has given of his capacity for the post he occupies.

FOR THE INFORMATION conveyed in last week's issue, that "Palms form seed," we are indebted to the printer. It is perfectly true that palms form seed in common with other flowering plants, but the heading written for the article was "Palms from Seed," the object of Mr. Prosper's paper being to show how palms were raised from seed. Printers have a great dread of putting into type what is plainly written, hence many of the blunders in scientific literature. In the *Gardener's Chronicle* of last week (p. 761, c. third line from bottom), we hear of a pelargonium called "Flower o Sprig." We could find such examples in plenty in searching through the *Field* and the *Farmer*, but it would be poor sport. Let us not, however, be too proud to receive from the printer the information that "palms form seed."

ARTISTIC BOUQUETS.—The *Guardian* says:—"Our lady readers, no doubt, are aware that the construction of a bouquet is a thing which ought not to be attempted except on an artistic principle. Now, it is an established principle of art that in a bouquet those colours which are called 'complementary' look better than such as are ordinarily said to 'harmonize.' But how are our fair readers to set the rule for ascertaining what are 'complementary' colours? We take the following solution of this knotty point from *Land and Water*, humbly suggesting to them to test it for themselves:—Cut out a circular piece of the petal of any flower and put it on 'white' paper, look at it fixedly for a few seconds with 'one' eye, then look off the colour on to a piece of white paper, and you will see a bright ring of another colour; that ring or circle is the right complementary colour or contrast to the colour in the petal." We may well have hideous bouquets while this hosh about "complementary" colours is offered as a doctrine for the formation of them. Where are the complimentary colours in a bride's bouquet? yet what more beautiful when well made?

TESTIMONIAL TO MR. BRUCE FINDLAY.—We have received a circular bearing the signature of Mr. Henry Whitworth, honorary secretary of the Manchester Botanical and Horticultural Society, the object of which is to invite subscriptions to a fund intended to be devoted to a testimonial to Mr. Findlay. The promoters of this movement have the approval and assistance of the council of the Society, and they anticipate that there will be a ready and liberal response to their appeal, not only from the subscribers to the Society, but from "others who have been brought into personal contact with Mr. Findlay." The admirable management of everything connected with the recent great exhibition at Manchester affords ample justification for the initiation of this movement, which, we feel assured, will be appreciated by exhibitors generally throughout the country. Probably the highest claim Mr. Findlay has upon Manchester itself is his admirable management of the beautiful gardens at Old Trafford, which, alas! Manchester does not value as it should, or we should not hear of the society being encumbered by debt. Communications on the subject of the Findlay testimonial may be made to Mr. Whitworth, Carlton Buildings, Cooper Street, Manchester; or to Mr. Richard Haworth, Old Trafford, Manchester.

THE LATE SIR WILLIAM HOOKER.—A memorial tablet, of beautiful design, the work of Mr. R. Palgrave, enclosing a cast in "Wedgwood ware" of Mr. Woolner's medalion of the late Sir William Hooker, is about to be erected in Kew Church, near the grave of the famous botanist. The medalion occupies the centre of a composition of panels that are decorated with ferns, &c., in low relief, the fronds being arranged so that their lines harmonize with their position on the monument; the panels are divided, and mounted in mouldings of white marble. The portrait is of white, on a ground of smalt blue, the foliage of white on a delicate green; huff is used for certain minor panels which appear round the head, and, like their more important companions, are decorated with ferns. Apart from the medalion, the charm of this work is in the exquisitely delicate execution of the fronds, which have been modelled with the utmost elegance and sense of natural grace by Mr. Palgrave, whose skill has been noted before by us on account of a monument in Reigate churchyard. It would be impossible to praise too highly the subtle beauty of outline, the quiet loveliness of the curves, and the wealth of delicate contours which appear in this remarkable specimen of modelling.

FOLIATION AND FLOWERING OF TREES.—Mr. T. L. Plant has published in the *Medical Times* the following table, from nineteen years' observations, showing the earliest and latest dates on which the foliage or blossom of various trees has commenced expanding, compared with the same observations in 1867:—

	Earliest.	Latest.	1867.
Balsam Poplar (<i>Populus balsamifera</i>)	March 6	April 19	April 15
Larch (<i>Abies Larix</i>)	March 21	April 14	April 14
Horse-chestnut (<i>Aesculus Hippocastanum</i>)	March 17	April 19	April 19
Sycamore (<i>Acer Pseudo-platanus</i>)	March 23	April 23	April 25
Damson blossom (<i>Prunus domestica</i>)	March 23	May 13	April 17
Lilac (<i>Tilia europaea</i>)	April 6	May 2	April 30
Beech (<i>Fagus sylvatica</i>)	April 19	May 7	May 1
Spanish chestnut (<i>Castanea vesca</i>)	April 20	May 20	May 4
Oak (<i>Quercus robur</i>)	April 10	May 26	May 3
Ash (<i>Fraxinus excelsior</i>)	May 13	June 14	May 16
Mulberry (<i>Morus nigra</i>)	May 12	June 23	May 16

THE MANGROVE.—At the last ordinary meeting of the Royal Botanic Society, the Secretary reported that the society had received several young growing plants of the mangrove (*Rhizophora Mangle*) from the West Indies, the first that had been brought to this country alive. They were indebted for their safe arrival to the great care taken of them by the officers of the Royal Mail Steam Packet Company.

CURIOUS ALLEGED DISCOVERY IN FLORICULTURE.—A Correspondent writes as follows: "I see many notices in the papers of wonderful discoveries in horticulture addressed to the *gobemouches*. I observe that you treat these as they deserve, and I am very glad you gave Mr. Heselton a word of good advice respecting his wonders. I have cut the enclosed from the *Gardener's Magazine* of Oct. 3, 1863; if reprinted, I think it might serve to put the public on their guard against a contemplated scheme of swindling respecting which rumours are afloat."—It is said that Mayor Tiemann, at his paint factory at Manhattanville, has accidentally made a discovery which threatens to revolutionize horticulture. One of the factory hands having thrown some liquid green paint, of a particular kind, on a flower-bed occupied by white anemones, the flowers have since made their appearance with petals as green as grass. The paint had in it a peculiar and very penetrating chemical mixture, which Mr. Tiemann has since applied, with other colours, to other plants, annual, biennial, and of the shrub kind, "the result being invariably that the flowers so watered took the hue of the liquid deposited at their roots." By commencing experiments early next year, during seed-time, and applying different colours, we shall, no doubt, soon be enabled to "paint the lily." This, however we can personally testify—that charcoal put to the roots of dahlias and other flowering plants will redder them vividly, flowers nearly white being thus turned to a deep red, sometimes altogether, and sometimes mixed with a little lighter hue in half-a-dozen varieties, from one and the same root. It has been repeated, and with success, for several seasons in France, having admittedly been tried there in consequence of reading the paragraph. [The reader is requested to notice that this "strange story" comes from the western side of the Atlantic.—E.D.]

BRIE COMTE ROBERT ROSE SHOW.

This exhibition, notices of which have appeared in several of your contemporaries, came off on Sunday and Monday, and was, in some respects, a very different affair to what might have been expected from the accounts of it which have been spread abroad. Brie Comte Robert is situated in a very pleasant country, twenty miles or so from Paris—a country without hedges or walls or ditches, yet picturesque and pretty, from the number of fruit trees dotted over the land, and with the ears of ripening wheat bending into the straight well made roads—a country with rich sandy loam and gentle hills like parts of Kent, but for the main part covered with wide level spreads of wheat and vines. Brie Comte Robert is an ordinary and rather straggling little French town, with an interesting old church, traced with the beautiful art of the olden time, and gray with the lichens of a thousand years; and, finally, Brie Comte Robert has a *fête* and rose show, as all the world has been informed of late. The rose show, although pretty and remarkable of its kind, is not quite a marvel, but simply an adjunct of the village fair. Now, the *fête* of a small place like this is not, at first sight, or when examined in detail, a thing to be enraptured with. Imagine a grassy yard or small field, in the centre of which are a few tables and the small hut of a person who divines the future; and here, and all around, a lot of small, meagre, clout-covered tents occupied with various things, from temporary restaurants and ginger-bread stalls down to diminutive hilliards and little dodges where the yokels of the district invest a sou a time, and now and then win a little work of srt worth about a centime. Imagine, in short, the mildest and smallest corner of Donnybrook fair with every drop of "divilmint" squeezed out of it, and you have a pretty good idea of the sight that greeted my eyes as I entered the show-yard of Brie Comte Robert.

But at one end there was a very large oblong tent, and on entering that a very different sight presented itself. There all was fragrance and beautiful colour. The roses were all arranged on the ground, in a bed about six feet wide around the interior of the tent, and many rows deep, each kind being generally inserted in a little earthenware bottle—the sandy bed which had been thrown up covered with young green barley, sown ten days or so before; and the effect was very pleasing. It was, indeed, better than when we see them arranged on tables or stages. In the centre of the tent were several raised beds and borders covered with roses plunged in moss, and busts of the Emperor and Empress of France. These central beds looked distinct and pretty, from being composed of fine red roses margined with a line of white ones, and *vice versa*. It would be wearisome and useless to give the names of the endless varieties shown. Suffice it to say, that the exhibitors (who are mostly people who grow roses largely to sell to Parisian nurserymen) emulated in quantity rather than in quality—one cultivation showing as many as 600 varieties of roses. Of course, the cultivation of such a number implies the keeping of a great number of very bad sorts. Any good rose shown is to be had abundantly in England, for as soon as a good one is raised in France a stock of it is secured by English rose growers. Quantities of the fine rose Maréchal Niel were shown, a variety which has long since been recommended in your columns, and is now becoming universally diffused. There was, however, one distinctly new rose shown—Clémence Raoux. It is in colour that it is peculiar, being of a rosy pink suffused and marbled with white, so that it looks like some camellias. This is all that requires to be said about this much-talked-of show.

VERTUMNUS, in "The Field."

LEICESTER HORTICULTURAL SHOW.

Leicester show was held July 9th and 10th, on the race-course. Though there is plenty of room, the race-course is not the place for a flower show, for there is not a tree or vestige of shade of any description; the ground is rough as a fallow field, and the expense of boarding the ground round is enormous. I think there are gentlemen in the neighbourhood of Leicester who would willingly let the show be held in their paddocks or parks, which would save all, or a great part, of the expense of fencing, and be a treat to the inhabitants of Leicester besides. The show was not a large one, but the productions were very good upon the whole. Class B, for amateurs, showed a very great falling off; and Class A (cottagers) was not so large as usual. The weather for once was beautifully fine; a wet day being almost certain for Leicester show, it was quite a treat, which brought many visitors, though not enough for so large a town, the receipts for the two days being only £165; and I think if there was a balloon ascent, or Mackney, or some attraction more than just the show, there would be a much larger attendance of visitors. This is a sensational age, and if we have not something new we are tired and dissatisfied. The following are some of the principal things exhibited:—Class C, for gentlemen's gardeners, 12 miscellaneous: 1st, Mr. Bolton, gardener to W. Worswick, Esq., with *Ananassa sativa variegata*, good; *Vinca oculata*, *Caladium Chantini*, good; *Stephanotis floribunda*, light; *Seafortia elegans*, *Medinilla magnifica*, with 32 spikes, fine; *Plumbago capensis*, *Erythrina cista-galli*, 9 spikes, good; *Maranta zebra*, not good; *Spherogyne latifolia*, beautiful; and *Caladium argyrites*, good. A good 2nd, Mr. T. Charlesworth, West Bridge Dye Works, with *Caladium Chantini* and *Bellemeii*, good; *Clerodendron Balfourii*, very good, with its beautiful bracts of Danish colours, and the only one in the show; *Allamanda Hendersonii*, fine; *Croton pictum*, *Plumbago capensis*, *Cissus discolor*, *Anthurium grandis*, good; *Rhynchospermum jasminoides*, *Ananassa sativa variegata*, rather stale; *Stephanotis floribunda*, and *Alcascia metallica*, fine.—6 Plants: 1st, Mr. Staples, gardener to J. Harriss, Esq., with *Lilium auratum*, *Hoya bella*, nice; *Maranta zebra*, *Caladium Chantini*, *Begonia parvifolia*, and *Stephanotis floribunda*. 2nd, John Thorpe, Littlethorpe.—4 Plants: 1st, Mr. Lambert, gardener to Capt. Pochin, with *Pteris longifolia*, *Caladium Wightii*, *Clerodendron fallax*, and the best *Rhynchospermum jasminoides* in the show. 2nd, Mr. George Geary, gardener to W. Brooks, Esq.—*Gloxinias* were shown by Mr. Bolton and Mr. Staples: 1st, Mr. Staples, with beautiful plants and well flowered of the following—*Loveliness*, *Majestic*, *Magnifica*, *Stellata*, *Sir Hugo*, and *Leon de Fremenville*, with 80 flowers. Mr. Bolton 2nd.—*Achimenes*: Mr. Staples 1st, with five plants of *A. Verschaffeltii grandiflora*, *longiflora*, *Dentonia*, *Carl Weltuth*, and *Dazzle*; Mr. Bolton a good 2nd.—*Pelargoniums* were shown nice and fresh for the lateness of the season: 1st, Mr. Lambert, with *Rose Celestial*, *Mudano Lemichez*, *Impératrice Eugénie*, *William Bull*, *Cloth-of-Silver*, and *Louis Miellez*. 2nd, Mr. Bolton; 3rd, Mr. Burton, gardener to C. Noon, Esq.—6 Bedding *Goraniums*: 1st, Mr. Bolton, with *Eugénie Mezard*, *Fireball*, *Vaucher*, *Christine*, *Golden Fleeco*, and *Lord Palmerston*. 2nd,

John Thorpe, with Jean Valjean, Clipper, Mrs. Pollock, Snowball, Gloire de Nancy, and Excellent.—3 Orchids: Mr. Brockhurst, gardener to A. Turner, Esq., 1st, with three of his Regent's Park heroes, viz., *Lælia purpurata*, *Saccolabium Blumei majus*, and *Aerides alfine*, all fine.—6 Ferns: 1st, Mr. Bolton, with fresh plants of *Adiantum formosum*, *Pteris argyrea*, *Blechnum corcovadense*, *Phlebodium aureum*, *Stenochleena scandens*, and *Adiantum cuneatum*. 2nd, Mr. Lambert.—6 Lycopods: 1st, Mr. Staples, with *formosa*, *cæsius*, *denticulata*, *stolonifera*, *Wildenovii*, and *compacta erecta*. 2nd, Mr. Bolton.—6 Fuchsias: 1st, Mr. Burton; 2nd, Mr. Evans; 3rd, Mr. Staples.

Fruit was well shown by Mr. Bolton, Mr. Sago, gardener to Earl Howe; Mr. Henderson, gardener to Sir George Beaumont; Mr. P. Draycott, and Mr. W. Draycott.

Cut Flowers were generally very good, roses particularly so for the very hot weather we have had, which formed one of the principal features of the exhibition. In the Nurserymen's Class, 48 Roses, open to all England: 1st, Mr. B. Cant, Colchester, very fine; 2nd, Messrs. E. P. Francis and Co.; 3rd, Mr. W. Draycott, Lumberstone.—24 Roses, gentlemen's gardeners, open to all England: 1st, Mr. R. Draycott, gardener to E. Strutt, Esq., Hallaton; 2nd, Mr. T. Draycott, gardener to T. T. Paget, Esq.; 3rd, Mr. Watts, gardener to Capt. Tibbitts.—24 Roses, amateurs, open to all England: 1st, Rev. E. N. Pochin, Sibley Vicarage, very fine; 2nd, Mr. E. Hunt, Leicester.—24 Roses, Class C (subscribers): 1st, Mr. W. Draycott; 2nd, Mr. T. Draycott.—12 Roses, Class B: 1st, Mr. Hunt; 2nd, Rev. E. N. Pochin.—6 Roses, Class A: 1st, Mr. Parker.—6 Roses, Class A: 1st, William Atkins. I cannot give the whole of the stands as shown, and if I could I think it would be trespassing on your space too much; and we have already had so many good stands, as shown at the different exhibitions, so I will enumerate the principal varieties: Anna de Diesbach, Beauty of Waltham, Baron A. Rothschild, Charles Lefebvre, Maytime, Doctor Andry, François Louvat, Jacqueminot, fine this year; La Brillante, Lælia or Louise Peyronney, Madame Boll, Madame Caillat, Madame Crapelet, Madame Wood, Madame Hector Jacquin, Madame Victor Verdier, Maréchal Vaillant, Pierre Notting, Séoateur Vaisse, John Hopper, fine; Victor Verdier, Ville de St. Denis, Baron Gonella, Souvenir de la Malmaison, Gloire de Dijon. New ones, or varieties not shown many times: Abel Grand, Alfred Colomb, very fine; A. de Rotalier, rough; Carl Coers, Claude Million, Comtesse de Chabriland, Duc de Rohan, Duke of Wellington, Duchesse de Caylus, Duchesse de Morny, Fisher Holmes, Denis Helye, Gloire de Vitry, King's Acre, La Tour de Crouy, Laurent Descourt, Lord Macaulay, Louis Magnan, Madame Brianson, Marie Baumann, Madame Knorr, fine in Cant's 48; Marguerite Dombain, ditto; Oliver Delhomme, Souvenir de Wm. Wood, Triomphe de Caen, Turenne, Xavier Delibo, Emotion, Michel Bonnet, not good as shown; Alba Rosea, beautiful; Devoniensis, fine in Rev. E. N. Pochin's 24; Adam, La Boule d'Or, L'Enfant Trouvé, Maréchal Niel, Souvenir d'un Ami, Vicomtesse de Cazès, and Triomphe de Rennes.

Verbenas were shown by Mr. Lambert, Rev. E. N. Pochin, and John Thorpe; Pansies, by the Rev. E. N. Pochin and Mr. Broughton; Pinks, by Mr. J. D. Hextall, Mr. Mason, and Rev. E. N. Pochin; Sweet Williams, Rev. E. N. Pochin and others; Ranunculuses, by Mr. J. D. Hextall. Vegetables made a tolerably good exhibition in all classes.

Miscellaneous.—Mr. Brockhurst showed a large group of plants, of which the judges thought nothing at all, though it contained the following orchids, many of which Mr. B. showed, and was first with, at Regent's Park, besides other plants, which altogether made a very interesting feature in the show. But what a pity to let private feeling sway in honest rivalry! The orchids were, *Odontoglossum hastilabium*, 4 spikes; *Cypripedium barbatum*, 38 flowers; *Cattleya Dowiana*, 2 flowers; *Aerides odorata* and *odorata purpurea*, *Larpenæ*, *Saccolabium guttatum Holfordii*, *S. guttatum oncidium*, *Papilio majus*, a new *Aerides*, not named; *Epidendrum cochleatum*, and *Odontoglossum citrosium*. Other plants were *Anthurium Scherzerianum*, with 3 of its coral-like flowers—thanks to Mr. Turner and Mr. B. for thus early bringing us this valuable novelty to look at; *Gymnostachys Verschaffeltii*, *Lilium auratum*, *Alocasia metallica*, *Thrinax elegans*, in the top of a tree-fern stump 5 feet high; *Pothos argyrea*, *Yucca quadricolor*, *Alsophila excelsa*, and many other plants, in all amounting to 50 or 60. Next in importance, Mr. J. F. Gardner presented beautiful skeleton leaves and dried flowers. I cannot describe their beauty; I only wish you had been there, so that you might have seen and believed. Mr. Watson, St. Alban's, showed his two very pretty tricolors, Miss Watson and Mrs. Dix, which were generally admired. Mr. Thorpe, of Leicester, showed his seedling tricolor and other geraniums, petunias, and verbenas, respecting which nothing can be said in this report, for reasons which the signature at the end will explain. Messrs. Hunt and Pickering had their Leicester vases, of which we ought to be proud to think Leicester can turn something out to the admiration of all.

JOHN THORPE.

HINCKLEY ROSE SHOW.

JULY 11TH.

This, the first attempt, was very successful, and it is intended to enlarge it next year, so that Hinckley may not be behind its richer neighbours. The show was held at Mr. Thomas Taylor's, White Hart Inn, which proved a decided success. Mr. S. Preston exhibited some nice healthy plants for decoration. Amongst them was the new double geranium *Gloire de Nancy*. Mr. Evaos, of Arbury, sent some very fine roses, and Mr. T. Payne, fuchsias—Blue Bonnet, Annie, Rose of Castille, which were greatly admired. Mr. Thorpe showed his new seedling Tricolor and other geraniums and verbenas, together with a box of roses. Mr. Taylor exhibited a collection of very fine potatoes, known as Bonser's Seedling, Milky White, Grant, King, Mona's Pride, Early Emperor, Wonderful, and Royal Ashleaf. Other persons sent cucumbers, strawberries, and flowers, which were very good indeed. The first and second prizes for twelve roses were equally divided between Mr. Hurst, Mr. Burbage, and Mr. Preston. Six roses, first class—1st, Mr. Hurst; 2nd, Mr. Preston. Six roses, second class—1st, Mr. T. Holwell; 2nd, Mr. T. Taylor; 3rd, Mr. Ross. Three roses—1st, Mr. Holwell; 2nd, Mr. Ross; 3rd, Mr. Taylor; 4th, Mr. Preston; 5th, Mr. Truslove. Twelve strawberries—1st, Mr. Truslove; 2nd, Mr. Knight; 3rd, Mr. Brocklehurst. Mr. J. H. Ward sent three dishes of very fine strawberries, which unfortunately came rather late, and which were awarded an extra first prize. The roses shown were in very fine condition. The judges were Mr. J. T. Cotman and Mr. John Thorpe, of Leicester.

LOUGHBOROUGH HORTICULTURAL EXHIBITION.

This was held in the Grammar School grounds, July 17th, and was undoubtedly one of the finest exhibitions ever held in the Midlands. They have, in the first place, beautiful grounds; second, a very liberal prize-list; and, thirdly, the committee are good caterers for the public—I wish I could say, and for the exhibitors. Mr. Jackson, of Derby, made a successful balloon ascent in his "Zodiac," and the band of the Coldstream Guards was engaged for the day. The weather was not so favourable as could be wished, showers falling often during the afternoon and evening; but still the visitors poured in, and I have no doubt the receipts will be heavy. Last year, with a fine day, £263 was taken at the doors. As I said, I wished exhibitors were as well cared for. Those that came from a distance and were there early had to move their plants no less than three or four times, simply because forecast was not made for space before all the productions were there, which is anything but pleasant when one has been travelling all night. And there were no exhibitors' passes, so those who went out after once going in had to pay for readmission. I have no doubt it will be altered by another year if presented at the proper quarter. The principal exhibitors in the large classes were, for gentlemen's gardeners, Mr. Bolton, Mr. Peachey, Mr. Chell, Mr. Maclean, Mr. Spibey, Mr. Branson, Mr. T. Draycott, Mr. Henderson, and Mr. W. Smith; in the trade class, Messrs. Hickling and Son, Mr. J. Smith, Mr. Bowman, Mr. E. Smith, and Mr. J. Thorpe; in the amateurs', Rev. E. N. Pochin, Messrs. Foulds, Heafford, Pallet, Hood, Cartwright, Harriman, Giles, Perkins, Pickworth, Miss Hogg, Captain Dobell, — Palmer, Esq., &c. Cottagers were more numerous than any other class, and theirs was a very fine exhibition of itself, and the amateurs' was nearly equal to it. The gardeners made a grand display of plants, and their tent was the centre of attraction. Among the subjects shown the following were very fine:—*Caladiums*, all the established varieties; *Sphærogyne latifolia*, *Lilium lancifolium album*, *Cyanophyllum magnificum*, *Hibiscus Cooperi*, *Alocasia metallica*, and *Macrorhiza* var., *Croton*, *Cissus*, *Stephanotis floribunda*, *Cycas revoluta*, *Ananassa* var., *Plumbago*, fuchsias, acbimenes, cockscombs, pelargoniums, balsams, geraniums, petunias, ferns, lycopods, &c. The trade class was not so large, though there were good fuchsias, geraniums, balsams, cockscombs, foliaged plants, &c.; and amongst cut flowers, roses, verbenas, bouquets, &c. Altogether one of the best exhibitions I have had the pleasure of visiting.

JOHN THORPE.

ANOTHER BED OF STOCKS.

On the 9th of March last (page 98) appeared a short paper on Stocks, in which I stated as clearly and as briefly as possible the routine followed in the experimental garden at Stoke Newington, to secure a display of double flowers. The principal object of that paper was to show that the simplest method of growing stocks is the best, and, with the flowers before me as I write, I am quite satisfied with my system, but at the same time anxious to avow that other methods adopted by other people are equally successful. My neighbour Mr. Chitty came to see my stocks, and invited me to go and see his. It is a fine old custom that of florists visiting each other; for, to say nothing of the immediate pleasure and benefit, it tends directly to keep alive the kindly feeling and spirit of generous self-sacrifice which establish floriculture amongst the humanities without regard to professors of moral philosophy. Well, I went to see Chitty's stocks, and found them forming a very pretty border in two close lines; the front line white, the next line back the sort called "lilac shaded rose," a pleasing shade of colour. These two lines of stocks have been very gay since the 1st of July; they were at their very best about the 8th, but they will continue to flower till October, and may be kept clean and bright by simply clipping off the withered spikes and the seeds. In my paper on "A Bed of Stocks," I named March 20th as the best day for sowing the seeds of the Ten-week class. Mr. Chitty always sows in the middle of January, in a moderate heat, and goes on with the cultivation the same as with any other sort of bedding plant, having them strong in pots by the end of April for planting out. Looking at his two rows, I must confess they appear to be as good as it is possible to grow stocks in this country, and better far than they are commonly grown. Selecting one plant as a type, I find it to stand nine inches high, and to form a round compact bush about nine inches in diameter, with thirteen very large and beautiful spikes of flowers. To say that the border is well dug and liberally manured previous to planting is needless, for no man worthy of enjoying the fragrance of a stock would deny it the little labour required to grow it to perfection. These two collections—Chitty's and my own—are not open to public inspection; but any of our London readers who wish to see stocks well done only need to visit Mr. John Fraser's Nursery, Lea Bridge Road, and they will be able to judge for themselves if the late sowing and planting small system is of any value, for the system propounded in the GARDENER'S MAGAZINE of March 9th last is that followed in the Lea Bridge Nursery.

Immediately after the publication of the article referred to, a correspondent, "S. B.," proposed a method of distinguishing double from single stocks while the plants are in the seed-leaf, or very soon afterwards. You will find his communication at page 117 (March 16, 1867), and the essence of it is that the plants which intend to produce double flowers show from the first a bunch of fibrous roots; but those which intend to produce single flowers show from the first tap-roots, or, as our correspondent described them, "carrot roots." We gave the communication in the writer's

own words, carefully abstaining from committing ourselves to any opinion upon it. Experienced readers of horticultural journals must be quite hardened to alleged discoveries of this sort. I think I can call to mind at least a dozen different proposals for distinguishing double from single stocks while the plants are in the seed-leaf; but we have never heard of any one who could carry out a system of cultivation based on any of these proposals to a perfectly successful issue. I put no faith at all in "S. B.'s" method; but it was so directly in our way to try it that on the very day it appeared, I took the seed catalogue (No. 131) of Messrs. E. G. Henderson and Sons and marked off a few varieties of stocks for the experiment, sent with the list the sum of 4s. 3d. in postage stamps, and obtained the seeds through the post a few days afterwards. The sorts ordered were those entered in the catalogue at pp. 49, 50, as Intermediate Hybrid Scarlet (No. 120), German Ten-week lilac shaded rose (No. 137), German Ten-week blood-red (No. 140), Large-flowering Globe citron-yellow wallflower-leaved (144), English Ten-week (145), White wallflower-leaved Ten-week (148). On the 29th of March the seeds were sown in pans, and placed in frames. In due time the plants acquired four or five leaves each, and we carefully sorted them in respect of roots, according to the formula of "S. B." I think it proper here to remark that I never do a thing of this sort alone: I make it a rule to have a practised hand and eye to help whenever there is something to be done out of which hereafter might arise any matter for dispute. So the stocks were sorted by two persons, both agreeing that the roots were easily distinguishable, some being decidedly fibrous, and some decidedly carrot-like, and very few indeed in such an intermediate state that there could be any difficulty as to which class they should be assigned to. Two borders were planted with them—the tap-roots in one, the fibrous roots in the other. Every clump was labelled with its number, character, &c., &c. They are now in bloom; and the cultivator who is not by long experience prepared for the result will be curious to know if in one border we have all double flowers, and in the other all single ones. Such should be the case were the rule given by "S. B." of any practical value. I should value it if amongst the fibrous-rooted we had a larger proportion of doubles than amongst the tap-rooted; for a larger proportion would be a gain at once, and a key to further gain by some expansion of the system. Well, the result? I am bound to say that all through the two lots we have double and single flowers in as nearly as can be the same proportions. By "the same proportions," I mean in reference to this selection of their roots; for, as to the whole bulk, double flowers largely predominate, and they are as fine a lot of stocks as can be desired, produced, it will be remembered, in the simplest possible manner. Some of the very finest are the "English Ten-week Scarlet," No. 145 in the catalogue (1867); the spikes are large, the flowers round and thick, like model rosettes, and the colour such as in a rose we should call "rich purplish rose," but which in stocks we call "scarlet." But I repeat that all are good, and the wallflower-leaved yellow varieties extremely pretty, though the colour is the palest primrose, certainly not "citron yellow." That there are single flowers amongst them is not to be denied; probably a bed or border comprising double flowers only in any quantity was never seen, except where pains had been taken to draw out the singles the moment they betrayed their character by their pointed buds. We have left all to grow, single and double; and the English Ten-week is conspicuous amongst them for size, colour, doubleness, and compactness of habit.

I want to know what is the exact proportion of double to single in plants properly grown from good seed. Having counted 80 plants in Mr. Chitty's row of white stocks (all that were planted having been left to flower, because blanks would not be allowed), we found there were 43 double and 37 single; and the double ones were so exceeding fine that, viewed from a moderate distance, the row appeared to consist of doubles only. We appear to have about one-fourth single and three-fourths double, which is a better state of things than Chitty's; but his best plants beat our best plants by just so much as we might expect from the advantage they have had of a longer season for growth previous to flowering. Of course, where the thinning process is carried out, we can learn nothing as to the average proportion of single and double, because they get rid of every single one the moment they detect its character. This plan is adopted by Mr. Fraser, and hence in his beds we see doubles only, or at least the occurrence of a few singles is a matter of mere accident.

Some of our stock-growing readers will object to the sowing of Intermediates on the 29th of March, or on the day we consider the best for the Ten-week varieties, March 20. But I always sow a few of those and the good old Brompton at the same time as the Ten-weeks; but reserve the main sowing of Intermediates till the 20th of July, on which day I like to sow them on ground as hard as pavement, on which has been laid about four inches of nice mellow soil. If we lose the 20th of July (a very possible occurrence where there is always an excess of work), the seeds are sown

in pans and kept in frames to make up for loss of time; but Intermediates should be sown everywhere between the 15th of July and the 10th of August. Whether sown on hard ground or in pans, they ought to be all potted off before winter, and be quite established in their pots before the turn of the year; but be wintered as cool as possible, and as soon as they begin to grow in spring have all the encouragement possible to promote free rooting in a generous soil, and a dwarf sturdy habit. Starving practices, such as using sandy soil of a poor nature, cramping the roots, &c., &c., tell upon stocks as much as upon any soft-wooded plants in our gardens; they must be generously treated, or they are not worth a place in any pot or border. But treat them well, and I think you may obtain from any seed, English or German, fine plants; the final character being, I believe, not the result of any peculiarity in the seed, but the result of vigour imparted to the plant by a generous system of cultivation. But my belief may be wrong; no man's belief is worth much. As a matter of fact, there can be no question that good stocks are only to be obtained by good cultivation, and there is no golden key at present known for distinguishing either in the seed or the young plant the double and the single varieties from each other.

S. H.

THE PROPAGATION OF VERBENAS AND SCARLET GERANIUMS.

THE flower garden for the season has not yet arrived at its climax of brilliancy; but notwithstanding that it is time we should be on the alert in the way of propagating and preparing for the ensuing year's supply: though, amidst the uncertainty of life's journey, it is possible that the hand which now wields the knife and directs the plans may not witness the result of its labours.

The majority of us adopt a mode of propagation which we conceive best adapted to the circumstances to which we are subject, and though our peculiar methods vary, yet we all more or less succeed. Perhaps there is nothing more difficult among the bedding plants to get the cuttings to root (if the operation is deferred beyond this month) than verbenas, although so comparatively easy to strike in the spring. What, then, may be the cause? Why, after this period the plants show such a disposition to flower that you are at some trouble to get cuttings that will strike; and besides, the wood becomes hard and thready, and in many instances infested with insects; for should dry and hot weather prevail for any length of time, such varieties as Purple King and others quickly become a prey to the attacks of red-spider and thrip, so that if you are anxious to procure healthy cuttings, the present is the season. Besides this, the operation will now cost about one-fourth the time and trouble than if further delayed. The simplest—and maybe one of the best—means I ever saw employed for economising space and time in the work of propagating, was by a young gardener who had the charge of a small but well furnished garden. His plan was to slightly stir with a fork the soil in the trench that divided the asparagus beds. On the space required for his purpose he would strew some coarse river sand about two inches in depth; into this he would dib all kinds of soft-wooded bedding plants in patches (except geraniums and calecolarias); and certainly they did root very readily. The growing shoots of the asparagus form a capital screen against the scorching rays of the sun, but at the same time admitting sufficient light and air for the benefit of the cuttings as they progressed. Of course, we do not at this season of the year consider that cuttings of bedding plants need the assistance of bottom heat to enable them to root. Thus, if you wish to use your spare box-lights, you may prepare a bed in the way recommended above, on the earth-level, for the reception of such cuttings as verbenas, &c. I would make choice of a spot that is well sheltered from the scorching rays of the midday sun. Having dibbed in as many cuttings of verbenas or other kinds as you may desire, in accordance with the space at your disposal, then gently water them and keep them close till rooted, only admitting air on fine mornings for the purpose of drying them. Let them have a sprinkling from a fine rose occasionally at the close of a very hot day. Remove all flowers and decayed leaves as they make their appearance, and otherwise keep them clean; as from being kept in a close atmosphere they are liable to damp off. Should mildew appear, dust them slightly with powdered sulphur.

Owing to the great pressure of labour in maintaining the outdoor work in good order, we are apt to postpone the propagation of the scarlet and other geraniums till some two or three weeks hence; then it is we sadly disfigure the beds by the slaughter we make in seeking to obtain the requisite quantity of cuttings. Although they will strike readily out of doors from the present time till the latter end of next month, yet if you desire strong plants, and to preserve your beds somewhat intact, then don't delay, but commence at once by securing some strong cuttings of the variegated kinds. The best of them I would recommend to be put singly into 60-size pots, and stood close together out of doors in a rather shady spot till rooted, when allow them more room to

strengthen their growth. That you may not spoil the beauty of the beds, it is best to allow an interval of a few days to elapse betwixt the periods of your procuring the cuttings. Some gardeners insert the most of their cuttings of scarlet geraniums in a prepared bed out of doors; for myself, I am rather opposed to that plan, unless I have plenty of convenience when potted for housing them during the winter months, as the most of us are somewhat cramped for space till the chrysanthemums and other late autumn-flowering plants are removed. The system of propagation that I pursue with scarlet geraniums is to insert a dozen or more cuttings in a 32 or 6-inch size pot, well drained. From the period of housing them to that of commencing to pot them off singly, which is about the latter end of January or beginning of February, I give them but just sufficient water to preserve their health. Previous to potting them their leading shoots are stopped, so as to cause them to be bushy.

The variegated varieties are very susceptible of the least damp. It is always best to store them away in the driest and most airy part of the house, and where they can have abundance of light. Almost every person has his favourite variety; but there are some sorts, such as Bijou, that are very strong growers. Those whose gardens are small should confine the increase of their stock to plants that possess a robust habit. Although there are numbers of good varieties constantly being introduced, yet we cannot afford to dispense with some of the older sorts, such as Alma, Countess of Warwick, Silver Chain, and Flower of Spring. But the selection of varieties is a wide subject, and I am content with having made a few practical suggestions on propagating.

JOHN F. McELROY.

LATE AUTUMN VEGETABLES.

Amongst the many cares that devolve upon the gardener, that of securing a good supply of vegetables of various kinds late in the autumn, is one of no small account. I have been thinking, Mr. Editor, that if the old man with the blue apron was to give a short paper containing the principal details of the system which he adopts to secure a good supply of late vegetables for a large family, it would perhaps be useful to some of the numerous readers of the GARDENER'S MAGAZINE. So, having a spare half-hour to-night, I have sat down with the intention of doing the best I can to make your readers understand, by my poor writing, the principal points to be attended to. But first of all, let me say that I hope every good reader will pardon me for being absent from these pages the last few weeks, for I have not been a willing absentee; a press of work and other important matters have kept the old man so much upon his legs of late, that he has not been in a condition for writing, and this must be my excuse for not being more regular with my communications, which I must confess would be a bad recommendation, if I wished to gain an appointment as a regular correspondent. But as I have passed so many years in this vale of tears, I know I cannot aspire to so honourable a position, and perhaps this makes me careless. But this is wandering wide from my subject, which I will now commence with all the earnestness that I can bring to bear upon the goose-quill.

Broccoli.—And first I shall say something about the Walcheren broccoli for a late autumn vegetable. I sowed a good breadth of this early in June, a fortnight behind my usual time, and to make up for this I sowed in a nice, kind, rich soil, in a cold frame. For some days it was kept moist by shading, until the seed vegetated, after which it was carefully attended to, and the plants are now getting quite strong; in fact, they will be ready by the time I want them, as I require them to take the place of a second crop of peas which are standing upon a south border. The peas are now ready to come away, but we shall not be able to manure and dig the ground for another week, so it will be near the end of the month before the plants can go out. This will be soon enough, as I do not want them to come into use before October, and I anticipate that they will carry me on to near or quite Christmas. Now, there is not time for your readers to raise plants so as to get a crop to come in at the same time as these, but they may beg or buy plants, and if planted out by the first week in August, in a rich deeply-stirred soil, they may safely reckon upon a fair supply of late autumn broccoli.

French Beans.—Then I require dwarf French beans as late as they can be had without forcing, and I will tell you how I manage it. We have a lean-to orchard-house, one hundred feet long and forty feet wide. Along the front of this I shall, about the 4th of August, sow a row of the Newington Wonder dwarf beans. If these are merely protected from frost, they will carry the supply on quite three weeks beyond those out of doors. If I had not this convenience, I should sow in a brick pit, or cold frame, about the same time. I should not put the lights on or give them any covering until the cold nights of October commenced.

Late Peas.—In deep rich soils late peas will go on far into October, but they must have liberal culture. It is no use to sow

them upon a hard battered surface; they want a deeply-stirred and highly-manured soil, and if dry weather occurs during the month of August, each side of the rows should be stirred up with a fork, and a copious drenching of manure-water given them, and then a heavy mulching of dung put on to confine the moisture. This and the avoiding of thick sowing is the only preventive against mildew.

Vegetable Marrows.—Sow some seed at once if you want them late, and plant out—or rather sow where they are to stand is the better plan—and, as soon as the cold nights of October approach, put a two or three light box or frame over them. This will help them amazingly, but it is no use to attempt to coddle up old exhausted plants.

There, Mr. Editor, the old man's fingers are too stiff to write any more to-night, so he will close this short article with a hope that it may be useful. THE MAN WITH THE BLUE APRON.

THE UNIVERSE.

A DREAM, BY JEAN PAUL F. RICHTER.

I had been reading an excellent dissertation of Kruger's upon the old vulgar error which regards the space from one earth or sun to another as empty. Our sun, together with all its planets, fills only the 31,419,460,000,000th part of the whole space between itself and the next solar body. Gracious heavens! thought I, in what unfathomable abyss of emptiness were this universe swallowed up and lost, if all were void and utter vacuity except the few shining points of dust which we call a planetary system! To conceive of our earthly ocean as the abode of death and essentially incapable of life, and of its populous islands being nothing greater than snail-shells, would be a far less error, in proportion to the compass of our planet, than that which attributes emptiness to the great mundane spaces; and the error would be far less if the marine animals were to ascribe life and fulness exclusively to the sea, and to regard the atmospheric ocean above them as empty and untenanted. According to Herschel, the most remote of the galaxies which the telescope discovers lie at such a distance from us that their light, which reaches us at this day, must have set out on its journey two millions of years ago; and thus by optical laws it is possible that whole squadrons of the starry hosts may now be reaching us with their beams which have themselves perished ages ago. Upon this scale of computation for the dimensions of the world, what heights and depths and breadths must there be in this universe, in comparison of which the universe itself would be a nihility were it crossed, pierced, and helted about by an illimitable wilderness of nothing! But is it possible that any man can for a moment overlook those vast forces which must pervade those imaginary deserts with eternal surges of flux and reflux, to make the very paths to those distant starry coasts voyageable to our eyes? Can you look up in a sun or its planets their reciprocal forces of attraction? Does not the light stream through the immeasurable spaces between our earth and nebula which is farthest removed from us? And in this stream of light there is as ample an existence of the positive, and as much a home for the abode of a spiritual world, as there is a dwelling-place for thine own spirit in the substance of thy brain. To these, and similar reflections, succeeded the following dream:—

Methought my body sunk down in ruins, and my inner form stepped out apparelled in light; and by my side there stood another form, which resembled my own, except that it did not shine like mine, but lightened unceasingly. "Two thoughts," said the form, "are the wings with which I move; the thought of *here* and the thought of *there*. And, behold, I am yonder, pointing to a distant world. Come, thou, and wait on me with thy thoughts and with thy flight, that I may show to thee the universe under a veil." And I flew along with the form. In a moment the earth fell back behind our consuming flight into an abyss of distance; a faint gleam only was reflected from the summits of the Cordilleras; and a few moments more reduced the sun to a little star, and soon there appeared nothing visible to our system except a comet, which was travelling from our sun with angelic speed in the direction of Sirius. Our flight now carried us so rapidly through the flocks of solar bodies—flocks past counting, except to their heavenly Shepherd—that scarcely could they expand themselves before us to the magnitude of moons before they sank behind into pale nebular gleams, and their planetary earths could not reveal themselves for a moment to the transcendent rapidity of our course. At length, Sirius and all the brotherhood of our constellations and the galaxy of our heavens stood far below our feet, as a little nebula amongst other yet more distant nebulae. Thus we flew on through the starry wildernesses; one heaven after another unfurled its immeasurable banners before us; galaxy after galaxy towered up into solemn altitudes before which the spirit shuddered; and they stood in long array through the fields of infinite space, like triumphal gates through which the Infinite Being might pass in progress. Sometimes the form that lightened would outfly my weary thoughts; and then it would be seen far before me like a coruscation among the stars, till suddenly I thought again to myself the thought of *There*, and then I was at its side. But as we were thus swallowed up by one abyss of stars after another, and the heavens above our eyes were not emptier, neither were the heavens below them fuller; and as suns without intermission fell into the solar ocean, like water-spouts of a storm which fell into the ocean of waters; then at length the human heart within me was overburdened and weary, and yearned after some narrow cell or quiet oratory in this metropolitan cathedral of the universe. And I said to the form at my side, "Oh, Spirit! has then this universe no end?" And the form answered and said, "Lo, it has no beginning."

Suddenly, however, the heavens above us appeared to be emptied, and not a star was seen to twinkle in the mighty abyss—no gleam of light to break the unity of the infinite darkness. The starry host behind us had all contracted into an obscure nebula; and at length that also had vanished. And I thought to myself, "At last the universe has ended," and I trembled at the thought of the illimitable dungeon of pure, pure darkness which here began to imprison the creation. I shuddered at the dead sea of nothing, in whose unfathomable zone of blackness the jewel of the glittering universe seemed to be set and buried for ever; and through the night in which we moved I saw the form which still lightened on before, but left all around it unilluminated. Then the form said to me in my anguish, "Oh, creature of little faith, look up, the most ancient light is coming!" I looked, and in a moment came a twilight, in the twinkling of an eye a galaxy, and then with

a choral burst rushed in all the company of stars. For centuries gray with age, for millenia hoary with antiquity, had the starry light been on its road to us; and at length, out of heights inaccessible to thought, it had reached us. Now then, as through some renovated century, we flew through new cycles of heavens. At length again came a starless interval; and far longer it endured before the beams of a starry host again reached us.

As we thus advanced for over through an interchange of nights and solar heavens, and as the interval grew longer and still longer before the last heaven we had quitted contracted to a point, and as once we issued suddenly from the middle of the east night into an Aurora Borealis—the herald of an expiring world, and we found throughout this cycle of solar system that a day of judgment had indeed arrived; the suns had sickened, and the planets were heaving, rocking, yawning in convulsions; the subterranean waters of the great deep were breaking up, and lightnings that were ten diameters of a world in length ran along from east to west—from Zenith to Nadir, and here and there where a sun should have been we saw instead through the misty vapour a gloomy, ashy, leaden corpse of a solar body, that sucked in flames from a perishing world, but gave out neither light nor heat; and as I saw, through a vista that had no end, mountain above mountain, and piled up with what seemed glittering snow from the conflict of solar and planetary bodies, then my spirit bent under the load of the universe, and I said to the form, “Rest, rest, and lead me no further; I am too solitary in the creation itself; and its deserts yet more so; the full world is great, but the empty world is greater; and with the universe increase its Zaarahs.”

Then the form touched me like the flowing of a breath, and spoke more gently than before: “In the presence of God there is no emptiness; above, below, between, and round about the stars, in the darkness, and in the light, dwell-th the true and very Universe, the sun and fountain of all that is. But thy spirit can hear only earthly images of the unearthly. Now then, I cleanse thy sight with euphrasy: look forth and behold the images.” Immediately my eyes were opened, and I looked, and I saw as it were an interminable sea of light—sea immeasurable—sea unfathomable—sea without a shore. All spaces between the heavens were filled with the happiest light; and there was a thundering of floods; and there were seas above the seas, and seas below the seas; and I saw all the trackless regions that we had voyaged over; and my eye comprehended the farthest and the nearest; the darkness had become light, and the light darkness; for the deserts and the wastes of the creation were now filled with the sea of light, and in this sea the suns floated like ash-gray blossoms, and the planets like black grains of seed. Then my heart comprehended that immortality dwelt in the spaces between the worlds, and death only in the worlds. Upon all the suns there walked upright shadows in the form of men; but these were glorified when they quitted these perishable worlds, and when they sank into the sea of light; and the murky planets I perceived were but cradles for the infant spirits of the universe of light. In the Zaarahs of the creation I saw—I heard—I felt, the glittering, the echoing, the breathing of life and creative power. The suns were but as spinning-wheels, the planets no more than weavers' shuttles, in relation to the infinite web which composes the veil of Isis; which veil is hung over the whole creation, and lengthens as any finite being attempts to raise it. And in sight of this immeasurability of life no sadness could endure, but only joy that knew no limit and happy prayers.

But in the midst of this great vision of the universe the form that lightened eternally had become invisible, or had vanished to its home in the invisible world of spirits. I was left alone in the centre of an universe of life, and I yearned after some sympathising being. Suddenly from the starry deeps there came, floating through the ocean of light, a planetary body, and upon it there stood a woman, whose face was as the face of a Madonna, and by her side there stood a child, whose countenance varied not, neither was it magnified as he drew nearer. This child was a king, for I saw that he had a crown upon his head, but the crown was a crown of thorns. Then also I perceived that the planetary body was our unhappy earth. And as the earth drew near, this child, who had come forth out of the starry deeps to comfort me, threw upon me a look of gentlest pity and of unutterable love; so that in my heart I had a sudden rapture of joy such as passes all understanding, and I awoke in the tumult of my happiness.

I awoke, but my happiness survived my dream. Oh, how beautiful is death, seeing that we die into a world of life and of creation without end! And I blessed God for my life upon earth; but much more for the life in those unseen depths of the universe which are emptied of all but the Supreme Reality, and where no earthly life nor perishable hope can enter.

PÆONY ROSES.

What showy things these pæonies are! and how comes it that they are not more generally cultivated? are everyday remarks in the flowery month of June, when they surpass all other hardy plants in the size of their blooms, while they yield to none in either the richness or variety of their colouring; and yet in most British gardens fewer herbaceous kinds are now to be seen than the eight which were figured and described by Queen Elizabeth's famous “Master in Chirurgerie,” in the “Herball or Generall Historie of Plants,” which he dedicated to “His Singular Good Lord and Master, Sir William Cecil, Knight, Baron of Burghley, Lord High Treasurer of England,” &c., and “to the courteous and well willing readers, from his house in Holborn, within the suburbs of London, this first of December 1597.” This home neglect of a magnificently conspicuous tribe of flowers is the more unpardonable, seeing that they are held in high estimation throughout the Continent; where improved varieties are annually raised and catalogued by the plant trade, few of which ever reach our shores, for the very conclusive commercial reason that here there is no demand for them. When urged to account for this anomalous treatment of pæony roses, florists avail themselves of some of the following or other equally untenable excuses in their own defence—viz., that their flowers are disagreeably scented, and only of short duration; that they are vulgarly gaudy, and only fit for decorating cart horses at village races, or when employed in rustic processions; that they take up too much room; that they have some injurious, or at least suspicious, qualities attributed to them which it is admitted have not been clearly defined; and that the climate of Britain is not so suitable for them as that in those parts of the Continent where they are grown and flowered in the greatest perfection. The flowers are, however, neither so disagreeably scented nor short enduring as is generally believed; but, on the contrary, those of some varieties of *Pæonia edulis*, as well as others, have rather an agreeable perfume; and, with a judicious selection of early, intermediate, and late sorts, a regular succession of them can be maintained for six or eight weeks, or until superseded by the scarcely less sized, and certainly not more agreeably scented, but more

highly favoured, flowers of the dahlia. That they should be considered vulgarly gaudy by any is a mere prejudice unworthy of refutation; and although most of the kinds are too large for growing in small flower parterres, this very quality fits them for situations suited for the showy magnificence of both their flowers and foliage, such as public parks and wide extended pleasure grounds, where free growing herbaceous plants are, or should be, profusely introduced by the sides of drives, and in many other suitable places. So far from possessing any injurious qualities, the *P. edulis* or *P. albiflora* of some authors and its varieties are used for food by the Dauria, Mongolian, and other inhabitants of its native regions, who boil the roots in soups and improve their tea by adding the ground seeds. The *P. officinalis* still maintains a place in the “Flora Medica,” on account of its seeds being emetic and cathartic, while its roots are reported to be anti-spasmodic. Early English herbalists recommend fifteen of the black seeds, taken in wine or mead, as being a special remedy for the nightmare and good against melancholic dreams—properties which need certainly create no alarm in admirers of the growing plant. This distrustful prejudice may have its origin in very ancient times, when the last species, or the *P. coralina*, and most probably hob, had wonderful and alarming properties attributed to them, for the *Baaras* of Josephus and the *Cynospastus* of other nearly contemporary authors was supposed to be a prony, the seeds of which shone at night like a candle, when they were gathered by the shepherd and others, but “the plant could not be plucked without danger, and he who first touched it, not knowing the nature thereof, perished; therefore a string must be fastened to it in the night and a hungry dog tied thereto, who, being allured by the smell of roast flesh set towards him, may pluck it up by the roots. Moreover, it is set down by Ælianus, Pliny, and Theophrastus, that the seeds must be gathered in the night, for if any man shall pluck of the fruit in the day-time, being seen by the woodpecker, he is in danger to lose his eyes!”

All the most showy species and varieties of herbaceous pæonies are admirably suited for the climate of Britain, and in most seasons the shrubby Moutan pæonies of China, or, at least, the hardier varieties among them, may be grown with equal success. Notwithstanding the very ungenial nature of the past spring, they are now to be seen in great perfection in many even of the most northern gardens, where ordinary care has been bestowed upon their cultivation. To ensure the universal admiration of these most magnificent of summer flowers, it is only necessary to introduce some of the first-class collections of both herbaceous and shrubby kinds from the Continent. Plant them on deep, rich, dry soil, of moderate or lightish texture, and give them plenty of room for their full development. If none of our enterprising nurserymen will do this; let it be effected by the managers of a few of our plant-decorated city parks, and they may depend that their success will soon induce numerous others to take up pæony culture. Nor let them be discouraged by some who will tell them that “their efforts will only result in failure, for we have tried it.” Some, we admit, have tried the introduction and cultivation of them; and after huddling the whole together, till the stronger overpowered the weaker, without allowing any room for developing their exuberant growths, they have generally decided on abandoning their culture, as being unprofitable, and consequently inexpedient.—*The Farmer.*

THE INFLUENCE OF FORESTS ON CLIMATE.

In the *Athenæum* of June 1 are two paragraphs bearing on this subject The first is as follows:—

We have frequently directed attention to the mischievous effects of the reckless cutting down of trees in France and southern Europe, where the climate becomes every year drier, and the soil is washed away by destructive floods, to the impoverishment of whole provinces. Warnings have long been uttered by competent observers, but in vain; a sort of rage for cutting down woods has prevailed for the last two centuries. But at length the people most interested—the inhabitants of the countries involved—have begun to open their eyes to the question, and a petition has been laid before the French Senate, which points out that the army might be employed in planting trees on the now barren hill slopes and plains. It would be something new to exercise soldiers in so peaceful and beneficial an undertaking, and we should be glad to see the experiment tried. Planting might prove more profitable than fighting; plenty would replace penury, and meteorologists would have the opportunity of witnessing a singularly interesting experiment.

The second paragraph refers to the Mauritius, and is in the following terms:—

During the past five years, the Meteorological Society of Mauritius have extended their system of observations so as to include twenty-two stations where the rain-fall is registered. Though the time is comparatively short since the system was adopted, some remarkable results have been obtained. At Cluny, a place in the south-east of the island, bordering on mountains and forests, the total rain-fall was, in 1865, more than 192 inches; at Gros Cailloux, 16 miles distant to the north west, the rain-fall in the same year was, omitting decimals, 36 inches. These figures give the highest and lowest quantity registered in Mauritius in the year. Another fact which has become apparent seems to strengthen the theory, much discussed of late, which shows a dependence between rain fall and forests. In some parts of the island, only a few years ago, a dry, cloudless day was of rare occurrence; whereas dry days are now frequent, and the cane-fields suffer from drought. Some of the rivers are much diminished in volume, and some streams have almost entirely disappeared; lakes and marshes are drying up; in consequence of which the yield of sugar-cane has decreased, and on some estates the cultivation has been abandoned. Other estates on the high ground near the edge of the forests, which were formerly considered too cold and wet for a good crop of canes, are now very productive. But with a continuance of the cause, it is believed that they too will become subject to the same effect. These, in the words of the report published by the Society, are “incontrovertible facts,” however they may be explained. And though there is no diminution in the rain-fall for the whole of Mauritius, the deficiency is great in districts in which “extensive denudations” have been made. It should never be forgotten that if forests have no other effect, they intercept some portion of the rain, and assist in preserving the humidity of the soil. When exposed to the full glare of the sun, springs and rivers dry up rapidly. Although these remarks relate to an island in the tropics, there is much in them that applies to our own island, where new theories of farming have of late years occasioned the destruction of miles of hedgerows and acres of timber.

BEDDING GERANIUMS.—No. XI.

Tricolors, Versicolors, Particolors, Tartans, or whatever else you mean to call them, fill a large place in the public mind just now, and for the next few years will run a pretty even race with the double-flowering kinds, which are in arrears in respect of relative popularity, but fast gaining ground, so that at the close of the present season we are likely to find them pretty even in the running. *Gloire de Nancy* will be the leader in the double class, as Mrs. Pollock is in the class of tricolors. Fashion is frivolous no doubt, but, apart from the frivolities and eccentricities of fashion, we are bound to regard the production of these two classes of pelargoniums as amongst the triumphs of modern horticulture, and to say with such plants before us that we live in an age of wonders, and man replenishes and subdues the earth, as he was commanded to do, as see Gen. i. 28. What shall we call these tricolors? It is hard to get rid of a name that has been generally adopted, and for that reason alone I should be content to classify them as tricolors, even though we may find half-a-dozen different tints in the leaves. The predominant are green, red, and yellow, or creamy white; the olive or black or brown of the zone contributes a powerful fourth element, shades of pink and brown contribute fifth and sixth elements, and a sharp eye may detect in the leaves of some a dozen shades, if old and young leaves are compared together, and the utmost is made of every tint perceivable. But the lovers of exactitude will not have the term 'tricolor' any longer, and it is far better to give way to them than to waste time in splitting hairs. The term which meets with most favour is ZONAL for the basis, and affix GOLD or SILVER to distinguish such as Mrs. Pollock from such as United Italy. This has the advantage of simplicity and perspicuity, and with the term lately adopted by the Floral Committee—namely, BRONZE ZONAL, for such as *Luna*—we may consider that we have the groundwork of a rational system of classification.

1. GREEN (or plain) LEAVED—Example, *Tom Thumb*.
2. ZONAL-LEAVED (dark zone)—Example, *Hibberd's Pet*.
3. NOSEGAYS (leaves green or zonal)—Example, *Stella*.
4. VARIEGATED (leaves margined white or cream)—Example, *Bijou*.
5. GOLDEN (leaves with yellow margins or yellow disks)—Example, *Golden Chair*.
6. BRONZE ZONALS—Example, *Luna*.
7. GOLD ZONALS—Example, *Mrs. Pollock*.
8. SILVER ZONALS—Example, *United Italy*.
9. DOUBLE-FLOWERED—Example, *Gloire de Nancy*.

We may divide and subdivide these hereafter; it is quite sufficient for the present to have a foundation to build upon; a big pigeon-hole, we may say, into which to thrust any and every variety we meet with, there to remain till we have time for further and more elaborate sorting. Let Nos. 7 and 8 for the present have a little of our attention, as this is the season to buy, and there are plenty to choose from in exact proportion to our means.

First of all, as to Properties, I can agree with Mr. Moore's code to a certain extent, but there is a point at which we part company. You will find his code in the *Gardeners' Chronicle* of May 18, 1867, very clearly stated, and in general tone and purport consistent with the habit of a man who observes and reflects much ere he speaks.* But the code fails, I think, at article 3, where he says, "The surface of the leaves must be perfectly flat, that is, neither concave nor convex, from contraction of the margin." I am led to this conclusion by observing that some varieties with convex leaves are extremely effective, for the convexity foreshortens the green disk, and places the margin and zone at more or less of an angle advantageous to the vision when we view the plant in a position below the eye. A concave leaf is of necessity most objectionable, for the disk becomes a dust-pan and impluvium, and the margin is foreshortened, and perhaps we see more of the under than the upper surface of the leaf—the back view of the elephant. If this be right, article 3 must be amended, and the attainable properties may then be stated thus:—

ATTAINABLE.

1. Plant of vigorous habit, stout and strong in growth, freely branching, and abundantly furnished with leaves set horizontally.
2. Leaf-colouring bright, distinct, and definite. The colours may be arranged radially, that is, in bars or rays proceeding from the centre, or in a regular series of orbs, circles, or arches, without radiate divisions.
3. The leaves must be circular, flat, or slightly convex, stout in substance, lasting long without change of colour. Concavity is a blemish; prominent lobes are a blemish; a very deep insertion of the leaf-stalk is a blemish.

POSSIBLE OR DESIRABLE.

4. The central disk may be green, and in that case should not occupy a space in diameter more than $1\frac{1}{2}$ times the breadth of zone

* A curious anomaly occurs in the article cited above. The writer says (p. 515 a), "It seems better to adopt [for the Tricolors, the more correct appellation of VARIEGATED ZONAL PELARGONIUMS." Elsewhere and everywhere Mr. Moore objects—and properly—to the use of the term "variegated" for any variety having golden-edged leaves."

and margin combined—e.g., if zone and margin measure 1 inch, the disk may be $1\frac{1}{2}$ inches. The central disk may be of any other colour than green, and in that case may occupy a space greater in diameter than $1\frac{1}{2}$ times the breadth of the zone and margin.

5. The zone may be of any breadth in excess of one-third the semi-diameter of the leaf, but must not be less than that. It may be an even segment of a perfect circle, or regularly waved, scalloped, or vandyked. It may be darkest or lightest coloured on the inner or outer side, but the colours must be bright, dense, decisive, and the boundary of the zone on both sides sharply defined.

6. The margin must be of one colour throughout, and that a clear dense colour, with none of the colours of the disk or zone breaking into it. When the disk is not green, it is desirable it should be the same colour as the margin, but any colour is admissible if effective and good of its kind. We may allow sixty points in all, namely thirty for attainable and thirty for desirable properties, and in the criticism ten will be the standard of perfection under every one of the several sections of the code. For the rest, knowledge and judgment are required; without these, codes are useless, and so we need say no more on this part of the subject for the present. We have got rid of Concolor, Bicolor, Tricolor, Versicolor, Particolor, and Tartan; got rid of Marbled, Whited, Radiated, and a heap of compound terms more hideous than the worst of the simpler kinds, and there is not a pelargonium of the great section of which *inquans* is the basis but may be put into one of our nine sections. Let us once more to the Tricolors, or, sticking to the new arrangement, to classes 7 and 8. We must at once make selections from the many varieties offered us, and find our way through a maze of entanglements to a few simple conclusions. It is as if we only wanted to walk to the next village, but must go through the Milky Way or swim through the nebula in the belt of Orion to get there. Well, let us pick out twelve of the newest, most distinct, and most useful of the Gold Zonals

A SELECTION OF TWELVE GOLD ZONALS.

Lady Cullum (E. G. Henderson)—Richest in shades of gold, yellow, and grass-green, with fine shades of red; a good grower, keeping its colour long, and in due time will be a bedder. Present price, 21s.

Lucy Grieve (E. G. H.)—Fine for the intensity of the red zone. Present price, 31s. 6d.

Sophia Dumaresque (E. G. H.)—In neatness of habit near fulfilment of the law of properties and regular balance of colours in disk, zone, and margin; one of the finest of all. Present price, 21s.

Meteor (Saltmarsh and Son).—Fine for properties, the leaf being almost circular and quite flat, zone rich in shades of red, margin fine chrome-yellow, very distinct, and fine constitution. 10s. 6d.

Queen Victoria (S. Perkins & Son).—Quite distinct and striking in colours, showing at a distance a blending of blue, scarlet, and gold colour, the disk being very dark or bluish green, the zone being fiery and the margin deep yellow. Will be a superb bedder. 10s. 6d.

Jetty Lacy (F. and A. Smith).—The form of the leaf good, the zone notable for splendid shades of chestnut, brick-red, and jet-black; makes a brilliant specimen. 42s.

Beauty of Surrey (F. and A. S.).—Margin brilliant yellow, zone rich amber with black shades and bars of bright carmine, small bright green disk; distinct and peculiarly rich. 31s. 6d.

Eclipse (F. & A. Smith).—Leaves rather too large, and too profoundly lobed, but the zone so rich in vermilion red that we must put up with the irregularities of form; a splendid variety, 21s.

Defiance (F. & A. S.).—Lemon yellow fading to straw colour, the zone carmine and black, with obscure patches of deep brown. There is so much blue in the red of the zone that when a fine plant is in fine condition there is a purplish hue perceptible, in pleasing contrast to the black, green, and yellow. 42s.

Mrs. Dix (Watson)—Very neat in habit, of medium size throughout, and coming near to win thirty in the three first sections of the code. Colours well balanced, growth good, and will in time be a bedder. 31s. 6d.

Louisa Smith (F. & A. S.).—Brilliant red, black, and gold colouring, and one of the neatest habited in growth. Worth a place, if only six were selected. 31s. 6d.

Titania (Carter & Co.).—Remarkable for the brilliant shades of red and the rich deep black of the zone, the margin being a beautiful shade of yellow. If we wanted only six, this must be one of them. 42s.

A SELECTION OF SIX SILVER ZONALS.

Queen Victoria (F. & A. S.).—Very neat in growth, margin creamy, sometimes pale sulphur, zone showing delicate and pleasing shades of red. 31s. 6d.

Princess of Wales (F. & A. S.).—Foliage large and abundant, margins creamy white, zones showing shades of black and purplish red; fine. 31s. 6d.

Impératrice Eugénie (F. & A. S.).—Showing as much colour as any of its class out; perhaps more colour than any of its class known. A slow grower, but constitution good, and safe for a bedder. 21s.

Caroline Longfield (E. G. H.).—A certain surpass of Italia Unità.

Wassand Hall Beauty (E. G. H.).—Peculiarly adapted for bedding, but as a pot plant not colour enough; the zone being a good shade of chocolate, with rather washy patches of rose. For elegant work in bedding invaluable. 21s.

Light and Shadow (E. G. H.).—A good zone on a good margin, peculiarly beautiful when in flower, and therefore well adapted for a specimen. 7s. 6d.

Between gold and silver zonals there is as great a difference as between gold and silver coins. As the white metal is the meanest of the two, so all the silver zoned varieties are weak, washy, ineffective, unsatisfactory, as compared with the best in the other section. But we must take the best we can get, and hope for better. Time will remedy this defect of the family of tricolors

SELECTION OF CHEAP VARIETIES OF GOLD AND SILVER ZONALS.

All obtainable at from 1s. to 2s. 6d. each.

Gold Zonals.—Mrs. Pollock, Sunset, Yellow Belt, Mrs. Benyon, Golden Defiance, Sunbeam, Socrates.

Silver Zonals.—United Italy, Honeycomb, Lady of Shallot, The Countess, Silver Star, Picturata.

A SELECTION OF FOUR NEW BRONZE ZONALS.

As no definite announcement has yet been made in respect of the sending out of Mr. Wills's series by Mr. Bull, I shall not attempt a selection. I know precisely which of them to vote for when they are all on offer, but to select in advance would be most imprudent. It is, however, quite impossible to touch this class without remembering that here Mr. Wills occupies a position parallel to that long since taken by Mr. Grieve in the gold zonal class.

Madeline Schiller (Carter & Co.).—If this is the same as was shown at the Crystal Palace on the 29th of June, it is a bargain at half-a-guinea, which I perceive is the catalogue price of it. The only reason, but a good reason, for doubt is that the variety I made notes of as one of the grandest of the Luna type was labelled "Schiller." This said Schiller, as shown on the 29th of June, is remarkable for the breadth, richness, and definiteness of its chestnut zone. One of the very best of this class. 10s. 6d.

Electra (E. G. H.).—A fine brown zone on a flat leaf; a free flowering variety. 10s. 6d.

Electric (Saltmarsh & Son).—In the way of Luna, with richer colours and heavier zone. Superb out of doors. 7s. 6d.

Venus (S. & S.).—Much gold and little zone, good habit, and flowering freely; very attractive and peculiar as a bedder. 7s. 6d.

A SELECTION OF CHEAP VARIETIES OF BRONZE ZONALS.

Luna, Beauty of Oulton, Bronze Queen, Goldfinch (useful only as a bedder), Canary Bird (useful only as a bedder), Mrs. Maxwell Hutton, Zingara.

The prices attached may prove to be wrong in many instances. I find the same varieties differ in catalogues of the same date so much as from half a crown to half a guinea, and in every case I have quoted the lowest figure. But there is a permanent element of delusion about prices. One house may appear extravagant in its charges, but the plants may prove to be worth all the money; and, on the other hand, some who go ahead in propagating manage to send out respectable samples at a very low price, considering what must be paid in the first instance for a few plants to cut from. We know very little yet of the constitutional vigour of the expensive kinds, for the simple reason that they are not allowed to grow. Very few cultivators can or will give them a chance. A plant that has its head cut off about once every six weeks all the year round can never show its capabilities fairly, and we cannot judge the high class zonals until they have had time to make themselves, under circumstances favourable to the formation of specimens, rather than to mere multiplication of plants. Seeing how hard they are propagated everywhere, we may say this of all of them—that they are better growers, and more vigorously constituted, than they have yet appeared. Mrs. Pollock had no constitution for some time after her advent, but now see what a growth is possible, and how surely it may be grown to perfection with but little more care than used to be bestowed upon Tom Thumb. Put fifty cuttings of Mrs. Pollock in a sunny border to-day, and on the 7th of September you ought to pot fifty good plants from that border. At all events, we can do so at Stoke Newington, and fairly conclude that other folks may do the same if they will but try.

S. H.

FLORAL.—There are two kinds of flowers which, although known to the world for years, have not appeared in the Gardener's Calendar—the Laughing Stock and the Post-t-Aster. The former is found in abundance on the first of April, and the latter may be heard of daily.—July.

CEYLON BOTANIC GARDENS.

Some time since, Mr. John Horne, Assistant-Director of the Botanical Gardens of the Mauritius, was despatched by the Government to Ceylon to inspect the plantations of Cinchonas, Teas, and Coffees, and to report upon them, with especial reference to the cultivation of these subjects in the Mauritius. His report has been published in full in the *Government Gazette*. As it is full of interest for our readers generally, and of immediate importance to many of our readers in the Colonies, we present the following abridgment:—

The Cinchona plantations are six miles from Newera Ellia, on the road between it and Badulla, and are about 4,500 feet above the level of the sea. They are surrounded on three sides by high hills, which open out towards the east and south-east, in which directions a beautiful view is obtained of the mountains about Badulla and the intervening grass-covered hills (Patna), with patches here and there of rhododendron, scrub and jungle in the ravines between the hills. The plantations face the north or north-east, and are partly sheltered from the south-west monsoon by the mountains, on the slope of which they are situated, and which rise in towering precipices for about 2,000 feet above and behind them, and are covered with jungle to their summits. From north to east they are protected from the dry north-east monsoon by high hills, which are also covered with jungle to their tops. Notwithstanding those natural protections, they do occasionally suffer from the wind which comes sometimes with almost hurricane force down the hills on which the plantations are, and along the pass through which the road from Badulla to Newera Ellia passes. A fortnight or so previous to my visit the plants had suffered severely from the gale, but were beginning to recover from its effects when I saw them. They had the appearance of being in good health and vigour, and were sending forth most luxuriant leaves and young wood. The soil in which they are growing is decayed vegetable matter, mixed with a large quantity of disintegrated gneiss. The surface is everywhere abruptly undulated and cut up with little ravines, which secure good drainage, a most essential point in Cinchona cultivation, for their hair-like and delicate roots soon rot, and the plant dies when they get into a marsh or badly drained soil. Across the slopes at short intervals canals are cut to carry off the water before it accumulates during heavy rains, and prevents it from carrying away the surface soil. Large blocks of gneiss are lying everywhere on the surface, which assist greatly in preventing the soil from being carried off, and prevents evaporation in dry weather. When the plantations were first made, the plan adopted in Java had been followed; clearing a place in the jungle for each plant, and planting them in the shade. The plants so situated grow well, but are lanky and drawn to reach the light and air, which are partly excluded below by the leaves and branches of the under scrub, and above by the leaves and branches of the trees. Not feeling satisfied with the appearance of the plants in the shade, a portion of ground (about eight acres) was cleared and planted, and the result is very gratifying indeed. In the ground so cleared, the plants are planted in rows, about eight feet apart, and about six feet from plant to plant. The cleared ground has been planted about four years, and the following is about the average height, &c., which the plants have attained.

Cinchona officinalis is eight feet, growing vigorously, flowering, and producing quantities of seed. Dr. Thwaites says that this kind would grow better in a colder climate than that of Hakgalle, and a few plants of it were tried at Newera Ellia, but they were killed by the frost in February, 1864.

Cinchona succirubra is about ten feet in height, and in excellent health. Some of the plants of this species have attained a height of about fifteen feet, and have stems of about four inches in diameter at the base; one or two plants of this species are, I am given to understand, coming into flower for the first time in Ceylon.

Cinchona paludiana has attained an average height of about five feet, the plants being as much in diameter; the base has a pyramidal shape, and is covered with beautiful luxuriant foliage and young wood, and a number of them are coming into flower.

Cinchona micrantha has in two years attained a height of about four feet, and are all in good condition.

The favourite kind of Cinchona in Ceylon is the *Succirubra*, which is planted to the extent of three to one of the *Cinchona officinalis* and the other kinds. It grows at a much lower elevation than any of the others, is hardy, easily propagated and transplanted, and yields a good percentage of alkaloid. It grows well from Peradenia (1,550 feet above the sea) to Hakgalle, and perhaps also beyond it.

All the kinds of Cinchonas that are in Ceylon are easily propagated by cuttings. At Hakgalle they lay out the cutting-ground in beds, three to four feet wide, in which the cuttings are thickly planted, and are protected from the wind, at the sides of the beds, by twigs stuck into the ground as thick as they will stick, and tied together at the top, about two feet from the ground, between two bamboos. They are protected from the sun by mats or palm-leaves. In this manner cuttings, carefully selected from hardy but not luxuriant grown plants, root and grow as freely as those of either geraniums or verbenas.

The mean temperature of Hakgalle for 1861 (I have the observations for that year only) is..... 64.6° Fahr.

Highest temperature..... 86° "

Lowest temperature..... 48° "

Greatest difference of temperature during the day.. 20° "

Rain fell that year on 198 days, but I have no register of the quantity. The rainy days were pretty equally distributed over each month of the year.

In Ceylon the tea-plant grows well, from the Botanical Gardens at 1,550 feet above the sea to beyond the coldest coffee regions, and from what I was informed tea will soon become an article of export from Ceylon. There are, I believe, about a hundred acres under cultivation, and an increasing demand for its seeds and plants, and information regarding its cultivation and manipulation. So much is this the case, that the Planters' Association is willing to bear one half of the expense of sending a man to India, if the Government will grant the other half, in order to obtain the desired information.

When the seeds are gathered, it is a good plan to throw them into a heap, and mix them with a little damp soil, and allow them to slightly ferment. As there are from one to three seeds in a capsule, fermentation rets it, and saves hand-picking to separate the seeds.

The seeds may be either sown at the stake, where the plants are to grow,

or in nursery beds prepared for them, and the plants afterwards transplanted.

If the former of these methods is adopted on a large scale, the labour in watering is very great, even were they sown at the commencement of the rains; whereas by the latter method, if the plants are planted when the rainy season has commenced, little watering is required, except in very dry seasons or sites.

The ground for the nursery beds should be drenched to the depth of one and a half feet, to allow the "tap root" to descend freely: the soil ought to be of such an adhesive nature as to admit of the plants being lifted with balls of earth at their roots. The beds should not exceed four feet in width, for convenience of watering, &c., and ought to be raised above the natural surface of the ground to prevent their being flooded during heavy rains. The most convenient distance for the seeds to be planted apart is about six inches, which will allow the plants to be lifted without injuring their roots. The place selected for the beds should have a free exposure to the sun and wind, which will make the plants hardy in growth, and they can then be freely handled when being transplanted. The seeds should not be covered with earth beyond an inch, and if a little litter is spread thinly over the beds it will prevent evaporation, and save watering, but it must be removed when the seeds begin to germinate.

The most convenient mode for a tea plantation is to have the plants planted in rows; but the distance between the rows and the plants in them might be regulated by the nature of the soil and the situation; five feet by four will, I think, be found convenient for most situations. At such a distance apart, holes should be dug at least two feet square, which will freely admit the roots of the plant without doubling them, which is injurious, especially when it is the "tap root" that is doubled. If the soil be poor, a little decomposed manure or crushed bones might be with advantage added. When the seedlings have attained a height of four or five inches, they may be transplanted, but if allowed to be a little older and stronger, they will not require so much attention and care.

Being anxious to receive information regarding the cultivation of the coffee, I visited the estates belonging to General Sir J. Cheap, and having been previously acquainted with the manager of two of them, Mr. W. Cameron, I resided with him for a few days, and made inquiries into the particulars regarding its cultivation &c.

The clearing of the ground of the jungle for a coffee estate is generally done by contract. When the trees are felled, those that are required for building purposes are selected and cut according to the size required; the others are allowed to remain on the ground until they dry, when they are set on fire. After all is consumed and the ground cooled, it is then laid out in rows, and holes are made to receive the plants. The distance between the rows varies from six to eight feet, and between the plants in the rows from four to six feet. Sometimes, but I believe seldom, the seeds are sown at the stake, and sometimes they are sown in nursery beds, and the plants are transplanted when they have grown four or more leaves.

These means are seldom resorted to when "stumps" from the jungle can be obtained in sufficient quantities. The ripe berries being carried to the jungle by birds, bats, and squirrels, and the pulp generally being the only part devoured, what with the shade and moisture of the woods the seeds quickly germinate, and thence young plants (stumps) can be obtained in most of the jungles in the neighbourhood of the coffee plantations.

The times selected for planting are at the breaking of the monsoons, when the rains begin to fall, and cloudy damp weather can be (comparatively speaking) depended upon to start the plants into growth.

At three years the plants begin to bear, and the yield annually increases, until the plants are about twelve years old. If well treated they will annually yield heavy crops for a long time. I was informed that some of the plants on Sir J. Cheap's estate, "Galapa," had been planted twenty-five years. They had no appearance of decline; on the contrary, they were in good health and bearing crops on an average of about eight or nine hundred weight to an acre, which is said to be a very good yield. The average yield of coffee per acre in Ceylon is said to be between five and six hundred weight; the latter figure is said by some to be too high an average.

Care has to be taken of the plant as it grows to keep it in a proper shape, and pruning has to be attended to at an early age. The coffee plant, like the peach, as a rule, bears its fruit on the wood which it has grown during the previous year. The pruning is done by the Malabars on the estate, immediately after the crop is gathered; the upright and cross-growing shoots are generally all that require to be cut out.

There are now no new cinnamon plantations laid out in Ceylon, and judging from what I saw, and the information I obtained from reliable sources, the greater part of the old ones are going to ruin. The soil in which the cinnamon is growing is almost pure sand, of a grayish colour. The plants are planted in rows about eight feet apart. It is cultivated and cut down in nearly a similar manner as oak copse in England. The cutting season happens twice a year, at the breaking of the monsoons. Only such suckers as have a light brown colour are cut, which might be termed thinning out. When cut the sticks are conveyed to the peelers, who take the bark off with a scimitar-shaped knife, round and blunt at the point for raising the bark, and sharp on the convex side for cutting the bark longitudinally on the stem. From the peelers the sizers take the bark and put the small pieces into the large ones, until they have an almost solid stick about three feet long. The bark passes from the sizers to the store where it is laid out, one stick thick, to dry in the shade, on racks made of coir, to freely admit the air all round it. The next process is to sort it into three qualities, and then make it up into hundles of about fifty pounds each.

I have heard it mentioned that it would probably be the best method to cultivate the *Cinchonas* in the same manner as the cinnamon and oak copse are.

The Royal Botanical Gardens at Peradenia are about four miles from Kandy, and they occupy a site which is said to have been a hunting ground of the Kandyan kings. They are about 150 acres in extent, and are bounded on three sides by the Mahawellaganga, which has, at the Gardens a width of about forty or fifty yards.

The surface of the garden is beautifully undulated, which gives a variety of scenery, and is sloping from the centre towards the river, the banks of which in some places are very steep. The soil of the gardens is generally very poor, almost gravel, but they enjoy a delightful climate for plants to grow in, which may besaid to do everything for them; the vegetation is beautiful and grand.

On one side of the drive from the main road to the garden gate are some splendid india-rubber trees, some of which are a hundred feet in height; and there are several other trees of the same sort in the gardens, larger in the trunk and taller.

On entering the garden, attention is called to a matchless group of palms, conspicuous among which is the "talipot" (*Corypha umbraculifera*), with its enormous leaves. The Singalose make mats of them, useful for constructing temporary dwellings and for other purposes. It is a most beautiful palm, attaining a great height, and when its leaves are fully developed it will have a diameter of about thirty feet.

Oreodoxa regia is here nearly forty feet in height, and bearing large quantities of seeds. *Borassus flabelliformis* (palmyra), second only to the cocopal in value to the native population, every part of the plant being made available for some useful purpose.

Next in height is *Caryota urens*, "Kittoolgass" of the Singalose. From the flowering stems of this plant toddy is drawn, from which a coarse kind of sugar is made by the Singalose. The wood is useful for building purposes. A good specimen of *Livistonia Mauritiana* (the "latanier" of Mauritius) is also to be found there, as well as others of great beauty and rarity.

To the right and left of the palm group are beds of scitamineous plants; behind them there are large flowery shrubs and trees, and in front of them showy-leaved Marantas, Caladiums, and a few beautiful annuals.

Leaving the palm group, and taking a walk, turning to the right, which leads to the "potting ground," the visitor passes through the spice garden, where there are some fine specimens of nutmeg, clove, and allspice trees.

After passing the nursery ground, keeping on the walk by the river-side, on the left there is a large young plantation of *Theobroma cacao* (chocolate) growing in the shade; on the right, between the walk and the river, there is a plantation of *Cardamoms* (*Elettaria Cardamomum*). A little further on the left there is a quantity of *Musa textilis*, which yields a fine flax, with which some of the finest muslins of India are prepared. Besides this species, most of the cultivated *Musa* (bananas) yield a fine and strong fibre.

From the *Musa* plantation, for nearly a mile, the walk by the river-side is through what has recently been a jungle, and all that is to be seen for that distance may be thus described. All the under-wood has been cleared out, and only the good specimens (one or two of each kind of the trees) have been left. Some of these are noble trees, and the most of them are covered with pipers, ferns, orchids, and some climbing aroids. The open ground caused by the thinning out is being filled with other kinds of trees and shrubs, natives and exotics.

At Dr. Gardner's monument, which stands on a knoll overlooking the river (the Mahawellaganga), are some fine *Aracariacs*, doubtless as beautiful and as graceful as they are to be found in Australia, and far excel those of the same kinds that are growing in Mauritius. There are also some fine plants of different kinds of *Cupressus*, *Thuja*s, and *Grevillea*s around the monument.

Not far from the monument there is a fine clump of *Bambusa gigantea*, which has canes about nine or ten inches in diameter. Arriving again at the entrance-gate, and passing the palm group, we enter the main walk, in the borders of which there is a fine display of flowers. The borders are backed by trees that have beautiful flowers, and are planted with the choicest flowering tropical shrubs, caladiums, roses, and showy annuals, which make them look very gay.

Passing along the main walk for about four hundred yards, we arrive at an unpretending shady path, paved with stones, from the river, which leads to the fernery. There are a great many things to admire in the Ceylon Botanic Gardens, but none are more worthy than the fernery. It is about an acre in extent, and has been so well planned, laid out, and planted, that it looks as if it were six. The greater part of the ferns are planted in beds, through the centre of which a canal passes that keeps the soil always moist. There is also a small rock-work for the kinds that grow either among stones or on them, or on trunks of trees. The canal, as it passes over the rock-work, has been so arranged that the water constantly trickles over the stones, which is highly beneficial for the ferns that grow upon them. The walks are four feet wide, and are all paved with stones from the river, and are edged with square stones. None of the beds exceed six feet in width, and the walks wind around each of them, by which means the plants are seen and easily examined. The Ceylon ferns are chiefly cultivated, some of which are beautiful and rare, with a good sprinkling of exotics.

The garden is all laid down in grass, which being pastured by cattle and with the magnificent trees which it contains, has the appearance of a nobleman or gentleman's park in England. JOHN HORNE.

MR. JAMES BATEMAN ON *LÆLIA MAJALIS*.

The last scientific meeting of the Royal Horticultural Society was invested with unusual interest, owing to a previous announcement that specimens of *Lælia majalis*, the *flor de mayo* of the Mexicans, would be exhibited in flower by Mr. James Anderson, gardener to Thos. Dawson, Esq., of Meadow Bank, near Glasgow. Until recently, this plant has all but been lost to this country. Messrs. Low, however, were fortunate enough in getting an importation, and from among these the three plants sent up to London by Mr. Anderson produced their gorgeous blossoms. Mr. Bateman made the introduction of them and their inflorescence the subject of a special lecture, under the presidency of Sir Roderick Murchison, Bart. He remarked that the plant was fortunate in having a history as well as a name, the native one being Itzumaquee; but it had besides two or three Spanish and several Latin names. After descending upon the value of orchids for church decoration, and their introduction upon a large scale in this way by the Spaniards, he proceeded to say that the first naturalist who went to Mexico was Hernandez, who published in 1648 at Rome a book, on the frontispiece of which two orchids were represented, the one being the beautiful *Lælia majalis*. Humboldt was the next to notice the species, under the name of *Bletia speciosa*, remarking upon the beauty of its flowers. Lexarza, who was a contemporaneous observer, stumbled upon the plant, and called it *Bletia grandiflora*. His description of this and some other of the Mexican orchids so impressed the youthful Reichenbach, that he longed to visit Mexico; but it was not requisite, as Mr. Barker despatched a collector, who sent home numbers

of this plant in blankets, but they never flowered. M. Deschamps, in 1837, brought home a cart-load, only one of them flowering in the collection of Mr. Dillwyn Llewelyn, which was figured in Mr. Bateman's work on the Orchids of Mexico and Guatemala, and by Dr. Lindley in the *Botanical Register*, 1844. These plates represent the plant throwing a spike of four to five flowers, which is an exaggeration, the best grown plants only producing one flower, and at most two on the spike. Dr. Lindley wished to call the plant *Lælia Grahamii*, and Dr. Reichenbach *L. speciosa*, but it was the *majalis* of cultivators, and so it ever would be. Mr. Bateman remarked that although Mr. Anderson had been the first to flower the plant successfully for the last thirty years, specimens were showing flower in the collection of Messrs. Backhouse, of York, and of his friend Mr. Wentworth Buller, of Exeter; and, strange enough, they had been grown under opposite treatment, Mr. Anderson growing his in a sort of Wardian case, where a circulation of warm air was continually taking place, keeping the plants as cool as possible during night, and allowing them occasionally during winter to live in a temperature of 33°. The other named gentlemen kept their plants in a dry and cool atmosphere all the year round, and it would take some time to prove which would be the more successful. The Meadow Bank plants were growing on flat tiles, a suggestion thrown out by Mr. Dawson, which seemed to be to the point, as the plants were in the best possible state of health. To these plants a special certificate was awarded, and to the same grower a first certificate for a beautiful rosy purple odontoglot called *roseum*. Several other cut flowers of note were furnished by the same exhibitor.

FOR THE WINDOW GARDEN AND THE OWNER THEREOF.

Striking geraniums to keep through the winter is to be the subject of this article; but I would first say to the professional reader, you must not be offended with the Old Man with the Blue Apron because he has taken up such a common subject to write about this week, because, if it is a common subject to you, with all your appliances for striking and wintering your geraniums, such is not the case with those for whom more expressly this is written. Therefore you must not consider it is presumption in the Old Man that induces him to sit down and write for a very worthy class of readers, because in this case he can leave the adepts to take care of themselves.

The greatest mistake made by those who have not a proper structure for wintering geraniums, is that they do not strike them early enough in summer to get them well rooted and established before the short chilly days of autumn; in fact, many of them do not think about it until the cold drenching rains of autumn warn them that their plants in the beds and borders are nearly over, and then they begin to think about and prepare for the next year's supply. The result of this is, that the cuttings they take are long, leafy, and sappy; and, for the want of a suitable place to propagate them in, where a suitable degree of temperature could be maintained, they soon become a prey to damp and mildew, and the operator has the mortification of seeing one by one damp off, as we gardeners term it, and in the end he finds he has but few, if any, left.

Could those for whom we write understand, as does the experienced gardener, the necessary conditions it is essential to secure in a plant that has some amount of rough usage to endure, to go through a long and trying winter in some indifferently-managed greenhouse, or in the parching air of a room, they would the better appreciate my efforts to serve them, and would be more willing to accept the advice which I shall give. But, as they have not the requisite knowledge to guide them, I must be content to give them in detail the instructions necessary to secure the plants in such conditions that every good gardener knows is essential in such cases. These conditions are an early-struck cutting that has been, from the time it was severed from the parent plant, exposed to all weathers from the first day of August until the end of September. In the first instance the cutting should be short, firm, and close-jointed, always avoiding those vigorous succulent shoots that are so tempting to the inexperienced cultivator, for they are always the first to succumb to damp or to a very brilliant sunshine; the side-shoots are generally the most preferable, as they are usually firm and short-jointed. Those springing from the bottom are often too sappy to strike freely. When it is practicable, cuttings should be taken during dry weather, as then they are less succulent, and will bear full exposure without suffering. But if cuttings are taken a few days after rain, all the organs are more heavily charged with water, and in proportion to the amount of water they contain so will they suffer when left to their own resources.

In speaking above about full exposure from the time the cutting is taken, of course I do not mean that all the varieties of geraniums that we now breed out are adapted for this treatment, because none of us would think of so treating the new tricolours; nor, indeed, is it desirable to do so with any of the variegated class, as, unless they have the shelter of glass, they are a long while in making roots. But all those that are usually called scarlets will strike readily in the open air. Why plants so raised are of more value for amateurs and window gardeners than those more tenderly raised is, first, that, having been fully exposed, they are more hardy; secondly, they have roots of a firmer texture and more in number than those raised under glass; and, lastly, the plant is more matured, and a greater degree of solidity is secured in its whole structure. It has, in short, a good constitution to begin with, and the best chance, therefore, of surviving the vicissitudes of a long dark winter.

I should advise my readers to use clean five-inch pots, with the drainage perfectly secured. The soil should consist of loam, leaf-soil, and silver-sand, equal parts, to be sifted and well incorporated together. The pots should then be filled to within half an inch of the rim, firmly pressed down while being filled. Round the sides of each pot place five or six cuttings, taking care that in making the hole to receive the cutting it is not made too deep, for if so the cutting will not reach the bottom, and there will be left below it a small body of air, which will prevent the roots from forming quickly. The cuttings should have a firm bottom to rest on, and the soil pressed firmly round them. They should then be well watered, and placed on a firm level bottom, fully exposed to the sun and all weathers. Should the weather be very bright immediately after the cuttings have been potted, a gentle sprinkle from a fine rose or syringe two or three times during the day will tend to prevent evaporation from the leaves, and will assist them the sooner to make roots. At no time should they be deluged with water; a sprinkle over the leaves every evening, with the soil just moistened about every third day, will be sufficient until they have made roots enough to absorb water, and then it must be increased. The latest date at which geraniums can be so treated must not be after the first few days in August, and,

indeed, the present period in July is not too soon, as the plants will be all that much the stronger. They should be removed to their winter quarters early in October, the pots first washed, and the plants cleaned of any dead or decayed leaves. All the time mild, open weather lasts they should have air night and day, and be watered sparingly all the winter, and on the approach of spring they may be potted off separately, or treated in whatever way best suits the convenience and taste of the cultivator. All the more tender kinds may be potted the same as the above, but they strike best when placed in a pit or frame.

THE MAN WITH THE BLUE APRON.

TESTIMONIAL TO MR. R. THOMPSON, OF THE CHISWICK GARDENS.

Though publicity in these columns has not been solicited by the promoters of the Testimonial to Mr. Thompson, of the Chiswick Gardens, we gladly place in the hands of our readers the following circular, which fully explains Mr. Thompson's claims on the horticultural public, and will, we sincerely hope, elicit a liberal response to so proper and well-timed an appeal:—

"The retirement of Mr. Robert Thompson from active duty in the service of the Royal Horticultural Society has been thought by his numerous friends to offer a fitting occasion on which to present him with a substantial testimonial, expressive of their cordial sympathy with him in his declining years, and indicating also their high appreciation of the many services which he has rendered to pomology and meteorology during a long and active life.

"The Council of the Royal Horticultural Society, acting as the exponents of the wishes which have been expressed that Mr. Thompson's services should be publicly recognized in this way, have taken the initiative by inviting several gentlemen connected with horticulture to attend a preliminary meeting, at which a committee was named to carry out the proposed object. [The committee consists of the Council of the Royal Horticultural Society, the International Committee, and other gentlemen connected with horticulture and meteorology; the Duke of Buccleuch, president; Mr. W. W. Saunders, vice-president; and Dr. Hogg and Mr. Thomas Moore, joint secretaries.]

"The many services rendered by Mr. Thompson both to horticulture and meteorological science are well known to those actively engaged in these pursuits, but it may be proper on such an occasion as the present to briefly recapitulate them. For upwards of forty years, then, he has held a prominent position in the working staff of the Royal Horticultural Society. He entered the Society's service in 1824, the second year after the establishment of the garden at Chiswick, and in 1826 was appointed to the charge of the Fruit Department, which then contained the finest and most extensive collection of fruits in Europe. At that time comparatively few of the varieties were known in this country, and the whole nomenclature was in a state of confusion, requiring unwearied application and perseverance to clear it up, so that the riches of the collection might be made available to the Fellows of the Society and to the country. In 1831 a 'Descriptive Catalogue' of these fruits was published, from memoranda taken at Chiswick, and in this valuable work Mr. Thompson, with great success, succeeded in carrying out his design of indicating the good and the bad sorts, together with their synonyms, and such brief characteristics as it was thought would be most generally useful. By means of this catalogue a knowledge of the superior kinds of fruits was much more rapidly spread throughout the country than it could have been by any other available means. The distribution of seeds of new fruit was consequently carried on with assiduity, and much consideration was bestowed in endeavouring to select such kinds as were most likely to succeed in the localities for which they were destined.

"While this important work was year after year being carried out, Mr. Thompson was engaged in making experiments both in the fruit and kitchen garden departments, carefully reporting the results; in taking descriptions of new varieties of fruits as they came into bearing; and in preparing another edition of the fruit catalogue, which was published in 1842, and a supplement in 1853. These descriptions and records have been of the greatest practical utility. Upwards of 2000 pages of the Society's various publications have been written by Mr. Thompson, but the fruit catalogue claims prominence, as having been the standard of fruit nomenclature in this country; while his 'Gardeners' Assistant,' a work not connected with the Society, may be characterized as the best and most scientific of compendious treatises on modern gardening.

"For a nearly similar period, Mr. Thompson has devoted much attention to meteorology. The meteorological journal of the Society, which was commenced in 1826, and which has been carried on by him since 1830, gives the readings of the barometer (corrected for temperature, &c.) morning, noon, and night; of the thermometer, maximum and minimum in sun and shade; and of the hygrometer; comparatively with averages of forty years, deduced from 219,000 observations of the various instruments. Such broad averages afford what must be considered as true means with which extremes may be compared as regards heat, pressure, and moisture. The observations of sixteen years have been translated from the Transactions of the Horticultural Society into those of the Royal Philosophical Society of Berlin; and up to the present time a weekly return has been published in the *Gardeners' Chronicle*. Among other papers from Mr. Thompson's hands, connected with this branch of science, is a Table of Temperatures for the use of gardeners, published in the Journal of the Horticultural Society, which furnishes an idea of the climate of some 900 places situated in different latitudes.

"With a modesty peculiarly his own, and with a degree of plodding perseverance which cannot be too highly recommended as an example to the rising generation of horticulturists, Mr. Thompson has worked on at these his favourite pursuits with zeal and assiduity, setting before himself the object of rendering service to science rather than that of personal gain; and now, after a long and useful career, when his physical powers begin to fail him, it has been thought that an expression of public sympathy in acknowledgment of his life-long labours would serve to gladden and solace the remaining years of his life.

"It is proposed that a subscription list be opened under the management of the committee, and that a money testimonial be presented as soon as a reasonable time for response has elapsed. Subscriptions, which will be duly announced, will be received by any member of the committee; by the Society's bankers (London and County Bank, Kensington); by the secretaries—Dr. Hogg, 99, St. George's Road, Pimlico, S.W.; and Thomas Moore, Esq., Botanic Gardens, Chelsea, S.W.; or by James Richards, Assistant-Secretary of the Royal Horticultural Society, South Kensington, W."

Calendar.

WORK FOR WEEK COMMENCING JULY 27.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN requires now a general clearance of plots that have borne peas, beans &c., to burn all the dry haulm and weedy stubble, and fork over and put on manure if necessary; all winter crops will do better in the ground well dug, even if not manured, than with a mere scratching of the surface. Where there is much demand for potting composts, the kitchen garden will supply useful material for the muck-pit, which is a more economical method in the long-run than the burning of rubbish, though the latter is a clean and quick way to get rid of it, and the ashes are useful. Save all the soot that can be got to make a puddle for dipping the roots of broccolis, cabbages, &c., when planting out from the seed-bed, and store away at once all pea-sticks worth keeping, to preserve tidiness and prevent waste.

Sow Early York, Battersea, Shilling's Queen, and Rosewort cabbage, Early Horn carrot, green curled endive, cabbage and cos lettuce, turnips, and prickly spinach. Make ready the ground for winter spinach, the time for sowing being near at hand.

CELERY newly planted will require abundance of water. Plant out as fast as possible, if any left in beds or pots. The fly has not seriously damaged the crop this season, and where it has not appeared there is now no further danger, and the late celery is likely to escape altogether.

WINTER SPINACH.—The time being at hand for sowing winter spinach, we are reminded of a peculiar failure of the crop which occurred to us a few years since. It may be worth while to state how this occurred. The ground was got ready in good time after potatoes, and was not manured. The spinach was sown as usual, and we had a splendid plant. But very soon after the plant was established, and the leaves were three inches long, they began to drop off suddenly. On scraping away a little of the soil from the plants that were affected, we found that detestable thing the larva of the Daddy Longlegs, which always attacks plants at the junction of the stem with the roots. Experience taught us there was nothing to be done. We might have wasted money on gas-lime, or on searching out the grubs by hand, but we knew too well the folly of attempting to cope with this pest in a remedial way, and quietly suffered the plantation of spinach to perish, which it did in a rather summary manner. But a preventive process may be adopted. Let the ground be dug a little earlier than usual, and left rough for a week or ten days. Then cart in a good dressing of manure, and have the whole piece trenched, and the manure put in the bottom of each trench. The plant will derive no immediate benefit from the manure, which is an advantage; for if we have a hard winter, it will endure the frost better in poor soil. Yet the manure is not wasted, for in the spring, when the plant begins to grow again, the roots will have got down on the manure, and in the dry weather of March we shall see the spinach producing huge fat leaves when other things are not growing at all. So much for the manure and the plant in their relation. You will now ask what about the vermin. Well, the first digging will expose the grubs; and the robins, and blackbirds, and rooks—so fond of newly dug or newly ploughed ground—will pick them up by thousands. Then those that escape death that way will be either buried in the trench at the next digging, or exposed to the view of the birds to be devoured. Thus the ground will be well cleansed for a year, and will not want manuring in spring, for the spinach will not consume all the strength of the manure. When the crop is removed, therefore, a deep digging with a four-tined fork is all it wants to prepare it for any kind of spring seeds, whether green crops or roots. As for other matters, all we need say is, lay out the ground in four-foot beds, sow in drills, and thin in good time to six inches apart. All sowings of winter spinach should be finished by the 15th of August.

Flower Garden

GERANIUMS should be propagated at once by cuttings put in the open ground in a sunny place, or singly in thumb-pots in frame or on a moist bed in a house facing south. If this work is postponed, the plants will be more difficult to keep through the winter. If quantity is an object, every two joints, one joint in and one out, will make a good plant; but one joint will do very well of any variety it is necessary to cut hard, as to form roots a joint in the soil is not necessary, as the internodes will root nearly as soon as the joints.

CARNATIONS, PICOTEEES, AND PINKS to be propagated largely now from layers and pipings, both easy and certain methods.

PANSIES to be propagated from cuttings of young wood; the old hollow stems are quite unfit for the purpose. Keep the cuttings shaded, and sprinkle frequently, but the soil of the cutting pans only moderately moist. Beds to be planted to stand over winter should now be deeply dug and manured, which will tend to reduce wireworm, as they will be turned up in the process and be destroyed. After the beds are made ready, set traps for vermin, and persevere to get the ground clean, as the losses in winter often arise through the eating away of the roots by marauders.

DAHLIAS want a heavy mulch after the ground has been lightly forked. This is said to harbour vermin, but practically its few disadvantages are balanced by the superior health of the plants and the beauty of the flowers, and the labour of watering is good rid of. As for earwigs, they always go upwards, and may be trapped with certainty.

ROSES may be multiplied by putting short cuttings, selected from the shoots of this season, in a bed of sandy soil, in a frame, keeping them shaded and sprinkled. Nine-tenths will root with ordinary care, and ninety-nine hundredths where the cultivator is quite *au fait* at propagating. Budding on brier and manetti stocks may be carried on. It is a good time to buy in new roses, and plant them, as they will be well established before winter, if taken care of, as to shading and watering, for three weeks after planting.

THE BEST BEDDERS.—The best bedders for amateurs are those which are used in greatest quantities at great places. Amateur cultivators generally suppose that in great places the means and appliances are so perfect that the planters there have ten chances to an amateur's one. This is a great mistake. In nearly every case the millions of bedding plants produced are the result not of first-rate appliances, but of appliances wretchedly imperfect, and so far inferior to what most amateurs possess that the managers of the great places are really those who deserve commiseration. The fact is important, because it teaches that the plants found most serviceable at great places are those that are most to be relied on for display

of colour, and which also have constitutions that adapt them to a certain degree of hard treatment. Among *geraniums* there are a few that surpass all the rest in absolute usefulness. Stella, crimson scarlet, is certainly the finest bedding geranium known. Crystal Palace Scarlet may be used with safety. The last named differs from Tom Thumb in being of more upright growth, and producing a richer and more continuous display of flowers. The fourth of this series is Christine, which in its colour and style is not surpassed as a bedder. Among *verbenas*, the most useful is Purple King; the next most useful, Mrs. Holford, Lord Raglan, Fox-hunter, and Ocean Pearl, which are all true bedders, and never fail to produce the effect desired of them when properly treated. *Tropaeolum* (Lobbianum section) of various kinds abound, but the best are Elegans, Eclipse, and Conqueror. *Lobelias* (of the Speciosa breed) abound, and several of them are of eminent service in bedding. The best are the true Speciosa, which is a fine deep blue; Blue King, which is a clear sky-blue; Paxtonia, creamy white and pale blue; and Compacta, which is of very dwarf, compact habit. Among SILVERY-LEAVED PLANTS *Centaurea ragusina* is the grandest of all. There are few who know how to manage this, and hence many inquiries come to hand. Plant a few strong specimens in a rather dry sheltered position, in sandy soil. Take during the summer as many side-shoots as you can obtain from those and from all others in beds, ribbons, &c.; strike those side-shoots, and house them in the usual way, and keep them rather dry all winter. The plants put out in the selected position are to remain there all the winter: if a mild winter, they will all survive; if a severe winter, they will not all perish. Those that survive will next season flower, and seed abundantly. Sow all the seeds, and go on again in the same way. This routine is soon told. It is worth a ten-pound note to any one who, for either trade or artistic reasons, wishes to grow a stock of this grandest of bedding plants. It may be well to add that *C. ragusina* and *C. candidissima* are one and the same thing, but the first is the proper name for it. Next to *Centaurea candidissima*, the best silvery-leaved plant is *Cineraria maritima*, which may be struck from cuttings at any time without heat, and which, if allowed to flower, produces seed abundantly. The next best, or we may say the equal of the best, but of quite different habit, is *Cerastium tomentosum*. Plant where it can remain, and it will be found quite hardy, and in spring will bloom beautifully. After blooming it should be cut close back, and will soon grow again and be as beautiful as ever. CRIMSON AND PURPLE LEAVED BEDDERS: the best are *Coleus Verschaffeltii*, *Amaranthus melancholicus*, and *Iresene Herbstii*. The first and last must be increased by cuttings on a north in spring; the other can be raised freely from seed sown in pans, very thinly covered, and placed in a very mild heat in February or March. The more hardy and less attractive purple orach (*Atriplex hortensis rubra*) is not to be despised. This plant will always propagate itself if allowed to do so, and its own way is the best way, because then they come at the season which suits them best. Allow a few plants to grow as they please, in the shrubbery, rockery, or border. They will flower and seed freely. Do not disturb the soil till some time in the next April; there will be hundreds of plants where the seed was shed. On a showery day lift them with a trowel and plant where required, and they will grow ten times more freely and more handsomely than by any artificial treatment. Self-sown plants growing in the full sun have leaves three or four inches broad, and of the richest shade of bronzy purple, and the plants attain a height of five or six feet.

ANNUALS for NEXT SEASON.—The finest show of annuals early in the summer is to be had only by autumn sowing. During the latter half of August and the first half of September is the best season to get them strong enough to stand the winter; if sown earlier they get too forward, and are apt to suffer from frost. An open quarter sheltered from the north is to be preferred, and the ground should be as hard as flint. On this hard surface lay down a shallow bed of poor sandy soil, and on that sow the sorts in rows pretty close together, each marked with a good-sized tally. In gardens that are very dry or insufficiently drained, the plants will have a better chance if the bed is made to slope southwards; this will carry off excess of water, and the plants will start better in spring. They are to be transplanted singly into beds, horders, ribbons, &c., as desired, as early in March as the weather will permit. The soil in which they are to bloom should be rich and well worked, and as every one of the plants will grow to twice the size ordinarily attained by the same sorts when sown in spring, they must be planted at double the ordinary distance apart. To make more sure, it would be as well to sow at least one pan of each of the same sorts as those sown on the border; these to be kept in a pit or frame and dealt with in the same manner for blooming. Some of the improved forms of hardy annuals are equal to anything we possess for brilliancy of colour and effect in masses; for instance, Iberis Kermesina, a new crimson candytuft, makes as grand a bed as the finest verberna or geranium in our collections, though it does not last in its prime more than four or five weeks. The old *Campanula speculum* is a charming thing for masses, the rich bluish purple of the flowers being enhanced by the white eye. Indeed, all the established annuals are worthy of more attention than they commonly receive, and will repay for all the extra care bestowed upon them, besides which they are particularly interesting as botanical studies. The following are among the best annuals to be sown at once:—Calliopsis, Clarkia, Collinsia, Convolvulus minor, Escholtzia, Godetia, Hibiscus, Dwarf Larkspur, Lupinus, Nemophila, Nolana, French Poppy, Schizanthus, Saponaria, Virginian Stock.

THE POLYANTHUS.—The polyanthus grower may be supposed to have in his possession now a few pods of ripe seed. What shall he do with it? Sow it directly—say within an hour of having read this. The best mode of procedure is to fill large pans or boxes with a mixture of two parts maiden loam, one part rotten cow or horse dung, one part leaf-mould, and one part silver-sand. The prudent cultivator will either bake or boil the compost before sowing the seeds. To bake it, place it in a hot oven for a few hours. The easiest way, however, is to boil it, as that is accomplished by first filling the pans with the mixture, and then watering it freely with boiling water, and when the soil is cool sow the seeds. It is very easy to say "Sow the seeds." The proper way to do it is to sprinkle them thinly on the soil, and then very lightly cover them with very fine earth of any kind, enough to hide them and no more. These seed-pans ought not to require any more water till the seedling plants are up, and the proper place for them is a cold frame facing the north, a sheet of paper, or a tile or slate, or empty pan laid over each, to prevent evaporation, and after ten days from the date of sowing to be looked at daily, and the moment the seedlings appear remove the covering. But suppose they do want water before the seeds germinate, there's the rub! Well, if you fill a water-pot and put on the rose, and give the pans a good drenching, you will wash every seed away, and make an end of your troubles completely, for you

will probably not see a single plant in any pan which has been so operated on. But there are more ways of killing a dog, &c. The neat way to water these seed-pans, and all other seed-pans, is to quietly lower them into a tub of water, and leave them there till the soil is wetted through. Don't drop them in carelessly, so that they will be instantly submerged, or the seeds will be floated up with the rush of hubbles, but gently rest them on empty pots, bricks, &c., so that they are plunged to the rim, and no deeper; so that, in fact, the water does not spread over the surface at all. Now for a last word on this subject. It is the one great secret of raising seedling polyanthuses, auriculas, and a hundred other good things. *The soil in the seed-pans should never be dry.* If it ever gets dry, you may expect that some of the best seeds will perish. You may, indeed, have plenty of plants even if the seed-pans are very carelessly treated, and are many times dry before the plants appear. But we repeat that dryness at any time is sure to kill the best seeds, so those who are most watchful are likely to have the best seedlings out of a batch. It is a good plan to divide a parcel of seed into two parts, to sow one part as soon as ripe, and the other part to be kept till spring. If you have plenty, adopt this plan; if not, then sow all at once, and pot separately all the seedlings as soon as they are large enough to handle. Potted polyanthuses in the full sun now will be nicely roasted and half killed. If you want to keep them, let them be shaded from eleven to three, and let them have plenty of water. Go at once and see if there is green-fly or red-spider on any of them, and the only way to ascertain is to search the under side of the leaves. If you find fly or spider, be brisk with remedies. Tobacco-water applied with a brush is a good and cheap remedy. Better still the "Aphis wash," sent out by the City Soap Company. Pour out a tablespoonful of the treacle-like fluid, and half a pint of water, mix well, and wash the under sides of the leaves with the mixture. If the use of a brush is too tedious a process, lay the plants on their sides in a row, and syringe the under sides of the leaves with the mixture.

GARDEN FLOWERS.—*Oenothera fruticosa*, *Pentstemonis Jaffrayanus*, *angustifolius*, *glabrum*, *eriantherum*, and *barhatus*; *Sabbatia campestris*, *Agathyrus Sibericus*, and *Tartaricus*; *Agrostemma suecica*, *Eryngium aquifolium*, *Inula glandulosa*, *Silene maritima*, *Aconitum versicolor*, *Dianthus fragrans* and *serotinus*; *Delphinium moschatum* and *intermedium*, *Plumbago Europæa* and *Larpenæ*, *Aster macrophyllus*, *abbreviatus*, and *multiflorus*; *Globularia cordifolia*, *Glaucium fulvum*, *Oenothera macrocarpa*, *Rumex sanguinea*, *Teucrium Hyrcanicum*, *Eryngium aquaticum*.

Fruit Garden and Orchard House.

STRAWBERRIES.—Plant out the first lot of well-rooted runners in ground well manured, and shade for a week and keep well watered; these will at once form good crowns, and bear well next season. Lay more runners, always removing them as soon as rooted, as they do better for being on their own feet early, and distress the parent stools less.

FRUIT TREES that are still making young wood must not be stopped, or it will cause them to throw out useless side-shoots, and the less the knife is used among them now the better. Espaliers must be tied and nailed before the young wood gets too hard to be brought into regular order without injury.

POTTED TREES must have every necessary attention to complete their growth and ripen their wood. No more pinching, and the pruning of useless growths to be deferred till the sap is down. Peaches and nectarines to be put in a position where they will be roasted with sun-heat, as near a hot wall or fence. The lights of the peach-house should be off for a month at least, and any training neglected to be done at once, that the wood may ripen perfectly.

BUSH FRUITS require attention now that the crop is gathered. Thin this present year's growth, tie and nail all the bushes, on fences and wires, and give the trees their final shape for fruiting next year. Thin out the new canes of raspberry stools, so as to leave only three or four of the strongest to each. As soon as the fruit is off, cut the old canes to the ground, and tie out the new ones that the wood may get hard and ripe. If manure is plentiful, mulch the raspberries at once, but do not disturb the surface more than may be necessary to remove weeds.

Greenhouse and Conservatory.

GREENHOUSE PLANTS, especially hard-wooded kinds, will be benefited by a few weeks' exposure in the open air, to ripen their seasonal growth, and give them a stocky habit. This will afford opportunity for a general cleaning and painting of sashes, stages, walls, &c., and to clear out vermin from odd corners and old woodwork. Houses containing all ordinary kinds of stock to have air day and night; but most soft-wooded plants in flower will enjoy to be shut up for an hour after watering, and then to have a little air again.

FLOWERS OF THE GREENHOUSE.—*Anacamperos angustifolia*, *arachnoides*, *poliphylia*, *varians*; *Senecio speciosus* and *venustus*; *Crassula bibracteata*, *filicalis*, and *tetragona*; *Billardiera scandens*, *Mesembryanthemum album* and *bidentatum*; *Aloe depressa* and *nobilis*; *Hakea illicifolia*, *Adesmia viscosa*, *Anomatheca cruenta*, *Adama versicolor*, *Aganallis linifolia*, *Aloysia citriodora*, *Amphicomma arguta*, *Babiana villosa*, *Ricinus rutilans*; *Fuchsias*, *Zonale pelargoniums*, the pendulous *Celosias*, several *Salvias*, *Plumbagos*, and *Lobelias* are now in their prime.

ERICAS IN FLOWER.—*Vestita*, *mutabilis*, *jasminiflora*, *dichromata*, *Eweriana*, *globosa*, *obliqua*, *pregnans*, *Aitoniana*, *Irhyana*, *anrea*, *curviflora*, *suaevolens*, *Swainsonii*, *formosa alba*, *elata*, *alopeuroides*, *cruenta*, *Banksiana alba*, *margaritacea*, *ampullacea rubra*, *taxifolia*, *incana rubra*, *laricina*.

STANDARD GERANIUMS are often grown for decoration, and they are valuable both because of their beauty and their uncommon appearance. Countess of Warwick, Alma, Flower of Spring, Mrs. Pollock, Sunset, Luna, Cloth-of-Gold, and Golden Chain, as the most distinct in their several classes, are the best seven kinds to begin with for the formation of a collection of standards for grouping. But as to the sorts, there need be no restriction; select according to your own taste and judgment, bearing in mind that you will not only produce standards, but the heads of your standards will grow much faster than plants of the same kinds grown in the ordinary way. You want for the purpose a number of stout straight-stemmed geraniums of any kind; generally inferior kinds are chosen because they are to be used only for their stems. The best of all for the purpose are seedlings that have grown straight up to a height of one to three feet, as the sacrifice of their heads is a matter of very little consequence. On these stems graft the sorts required in the cleft mode of herbaceous grafting. This is the easiest of all grafting operations, and really requires but little practice to make the operator perfect. Cut back the stock to a place where the wood is half ripe: it must be sound and

hard, but neither green nor brown. Let the scion be in the same half-ripe state. Split the stock down an inch or an inch and a half, and if possible choose a place for the top of the stock where it breaks into two branches. The fork will be just the place for inserting the graft. Cut the graft to a clean wedge, so as to fit in the slit, so that the bark of graft and stock will meet on both sides if possible; if that is not possible, *they must meet on one side.* Tie up moderately firm with worsted thread, and paint over with grafting mastic or with clay paint. The work is now done. Place the grafted plants in a shaded pit or frame or greenhouse; give only as much water as will just keep them from flagging. On fine mornings sprinkle the tops slightly. Beware of strong sunshine or cold draughts. Three weeks after putting on the grafts, loosen the bandage slightly, but do not remove it till six weeks from the date of grafting. If grafts are put on now there will be time to get the junction well ripened before winter, and if the grafted plants are put in the stove in January they will make a fine growth for next summer's use. The leaves and shoots of the stock must be removed by degrees until the head alone takes all the sap.

CLAY PAINT FOR HERBACIOUS GRAFTING.—Take some soft clay and knead with a little water till it is of a pasty consistency; then put it into a clean vessel with a little more water, and work it about with an old brush till it is of the thickness of cream, free from grit, and semi-liquid. Paint the graft with this, and shake over the paint a little dry sand. Then paint again and again, each time shaking over a little dry sand, but always allowing the sand to dry before applying another coat.

Stove and Orchid House.

ORCHIDS must have every necessary assistance to ripen their pseudo-bulbs. They may have more light and air, and less moisture, but must be kept plump, and those that continue to grow all winter to be kept going steadily but without excitement.

STOVE PLANTS intended for early bloom next season to be shifted at once to their blooming pots; let the soil be *fresh*, and the shifts not greater than the plants can reasonably fill up, and have time to ripen their wood.

ORCHIDS IN FLOWER.—*Cynoches Loddigesii*, *C. ventricosum*, &c., *Epidendrum aloifolium*, *Cymbidium pendulum*, *Epidendrum rhizophorum*, *Cypripedium barbatum*, *C. Farieanum* and *Lowii*, *Dendrobium Paxtonii*, *Galeandra Bauerii* and *cristata*, *Huntleya meleagris*, &c., *Miltonia bicolor*, *M. candida*, *M. spectabilis*, *Peristeria elata*, *Burlingtonia Knowlesii*, *Irelia autumnalis*, *L. majalis*, *Oncidium pulchellum*, *O. Batemannii*, *O. flexuosum*, *Promeneas stapeloides*, *Cattleya granulosa*, *C. Harrisonia*, *C. labiata pallida*, *Odontoglossum grande*, *O. phalaenopsis*, *Saccolabium Blumei* and *B. major*, *S. furcatum*, *Sobralia liliastrum*, *Stanhopea Martiana*, *S. insignis*, *tigrina*.

Replies to Queries.

A. P., Mere House.—The plant is *Linaria cymbalaria*, sometimes called *Antirrhinum linaria*. The first is the proper name. It is a beautiful plant for an old wall or rockery.

Geraniums Diseased.—**W. G.**—As only two plants out of about three hundred are affected, there does not appear to be any peculiar case for inquiry. When the young leaves become spotted, and the flowers die before opening, we may reasonably conclude that the plants have been too wet and too cold at the root.

Hard-wooded Plants.—**J. H.**—The precise treatment required for each of your plants cannot be given in a general reply; nor can any one without seeing the plants say much about what should be done with them. You may safely prune them back at once if they require it, to keep them symmetrical, and to promote a dense bushy habit, and three weeks hence you may shift them on to the next size pot, if they appear by their size and vigour to require more pot room. The plant you are in doubt about is *Genetyllis Hookeriana*.

Bees.—**K.**—So far as we understand your case, you wanted to make an artificial swarm and failed. The season is now so far advanced that you must not indulge in any more experiments, or you will lose your bees in the winter. You had best stop up the entrance to the old hive, and force the cast into a good working; if you do this at once, the cast, with its additions, will become a good stock before winter. About three weeks after take the old hive and drive the bees out. A few days before taking it, ventilate it rather liberally, with a view of inducing the queen to go down, giving the bees the choice of the old or young queen. We advise this course because you want the honey. Were we personally concerned in the matter, we should prefer to make two stocks, and should at once remove the old hive to make an end of the connexion, and enrich the cast by more strays from it.

A. B.—Probably the larva of the wood-leopard moth ate the pith out of the stem of the tree, and caused its death. This huge and hungry grub always leaves a hole bored in the tree it has lived in, so you may reasonably search for evidences of its residence. We do not think the little brown beetles had anything to do with it.

W. K. C.—Your plant appears to be *Disemma aurantia*, but we cannot speak with certainty, for it came to hand shrivelled up, and fell to dust while under examination—a common occurrence with plants packed in dry cotton-wool. One or two leaves and a flower placed between fresh ivy-leaves, in an ordinary letter, and directed to Stoke Newington on a Monday or Tuesday, would suffice us for its determination.

J. George.—Your seedling zonal, with delicate pink and white flowers, is beautiful. Your twenty (or more) varieties of tropæolums are interesting and pretty, but we have no time to expend in exploring such a heap. If you like to select three or four, we will look at them attentively, but when flowers come in this wholesale way we at once put them out of the reach of criticism and identification.

J. Evans.—No. 2 appears to be the best sample. The other subjects next week.

Brake.—**S. B.**—The real question about brake is not how to grow, but how, if you once begin, to get rid of it if you wish to. In your rockery you had best set apart a space for the brake; if you plant it with and amongst other ferns, it will soon spread and kill them all out, and become master of the situation. The brake will grow in any mellow loam or peat, but not in common garden soil or poor chalky soil. To establish it take up the roots at any time, and plant them where required. After one year's growth it will become luxuriant, and one of the most glorious ferns ever seen in a garden.

The Gardener's Magazine.

SATURDAY, AUGUST 3, 1867.

WINDOW GARDENS ASSUME MANY FORMS, but we seldom see plants grown or displayed in windows in a thoroughly satisfactory manner. Usually the display consists of plants in pots, and that is better than nothing, if the plants are good. But the appearance of the pots is not pleasing, and frequently, when these are hidden by being placed in boxes, neatness in the external view is obtained at the expense of ugliness in the view from within the room so embellished. There are other reasons, too, for concealing the pots from view, for what the eye sees with some degree of revulsion the sun shines on with some degree of injury to the plants; and, as a rule, zonal pelargoniums are the only subjects that will endure the roasting to which they are exposed in windows when the sun shines full on the pots. Yet it is not desirable to be restricted to the selection of one class of plants only for windows; we want methods of embellishing windows with plants equally consistent with good taste and the preservation of the plants from injury. It must be borne in mind that the embel-

ishment of windows is not a matter of trivial importance. Thousands of persons fond of flowers are during a great part of their lives confined to the house, even where there is ample garden space, and thousands more have no greater demesne than the window affords. Even in breezy country villages window gardening is pursued with ardour; but in towns it seeks to rank amongst the rural arts, but is generally somewhat in arrear of the rest of the arts to which it is allied.

Those who are familiar with the western parts of London must have noticed of late the increase of a very elegant form of window garden, consisting of a glass case projecting beyond the plane of the window sashes—a sort of vertical bow-window constituting the lower sashes; and in these cases elegant groups of plants are seen at all seasons of the year. There are some charming examples of these window gardens attached to the windows of mansions in Piccadilly, Cavendish Square, and other districts, where the residents are mostly wealthy persons who pass some months of the year in town, and the remainder far away at elegant country seats, where the luxuries of horticulture surround them in every imaginable form. We have seen in these window gardens ferns, evergreen shrubs, and flowers, in the depth of winter; and further on in the season, roses, pelargoniums, and many other suitable plants; and from time to time other subjects selected from the floral wealth of successive seasons; and we have observed that while the inmates of the apartments so embellished must derive much pleasure from seeing and keeping these gardens, they afforded their share of gratification, too, to the passers by—were, in fact, adornments of the exterior of the residence, and a boon to the pedestrian in the street.

Fig. 1.

Fig. 2.

Given a simple idea of this sort, and a skilful manufacturer will soon vary it to suit many tastes and circumstances. Generally speaking, the inner and outer sill together are made available to give considerable breadth to these cases; that is to say, breadth at right angles to the wall in which the window is set, without any greater projection beyond the line of the wall than is consistent with safety and convenience. The lower sash perhaps is removed, and a plant-case takes its place. In many parts of great towns it is necessary to exclude the view of the street, no less for the privacy of the inmates than their protection from absolute offence and annoyance. The ordinary means of accomplishing this is to "frost" the glass with an alkaline salt, or to put on a thin coat of paint, or to employ embossed glass. But a plant-case accomplishes the same, and more agreeably and quite as effectually, and renders the house cheerful within and elegant without. When the exterior appearance is a matter of the first consideration, such a case as that shown in figure 1 is admirable, and the plants are of course to be adapted to the aspect and the tastes of the possessor. In a place from which sunshine is excluded ferns are, as a rule, the best for the purpose, if they are planted in the case; but if pot plants, plunged in a bed of cocoa-nut fibre, or some other clean and suitable material, are employed, flowers may be freely used, because they can be changed frequently, and temporary residence in a sunless aspect inflicts but little harm upon them.

In other cases, where the embellishment of the interior is the

In other cases, where the embellishment of the interior is the

matter of highest importance, an aquarium can be fitted to the inner side below the level of the sill, and in this case exterior embellishment is possible by forming a bank of ferns on a miniature rockery above the water. The two examples figured will show that any taste may be gratified by varying the fashion and the contents of the cases. A slab of slate is the best foundation, and this should be pierced for drainage where plants are grown. A depth of four to six inches will usually be found sufficient for the small plants that are best adapted for such cases. But in a window of ordinary dimensions a depth of nine inches for soil could be obtained without difficulty, and an elegant moulding on both sides of the case suffices to hide pots and soil from view. Messrs. Barr and Sugden have considered all these matters, and have produced a great variety of suitable cases, and make it part of their business to provide suitable plants for them. We have but to direct attention to this subject, we feel assured, to secure it the interest of those of our readers who are not yet satisfied with the state of their windows in respect of plant embellishment. While on this subject, it may be seasonable to add that a few years ago Messrs. Barr and Sugden produced a very useful form of open box for windows. These were made in every variety of style imaginable, some having rustic work in front, others with architectural fronts to harmonize with stone and stuccoed walls. We have had some of these boxes in use three seasons, and they have proved of the greatest service, the plants, being planted in them, requiring far less attention than plants in pots, and making as free a growth and bloom as plants of the same kinds in beds; whereas plants in pots in windows, however gay for a time, soon become exhausted and have to be renewed two or three times during the summer. The glass cases are of course to be preferred, where a portion of the window can be permanently given up to them, as in these a display of beautiful vegetation can be secured without difficulty the whole year round; for in the depth of winter the plants derive a considerable degree of warmth from the room, and it is even possible to heat the cases in the same manner that the plant-cases manufactured by Mr. Gray, of Danvers Street, Chelsea, are heated, by means of a boiler periodically filled with boiling water. When lately visiting the works of the Patent Concrete Stone Company, we saw many elegant examples of window boxes made of cheap imperishable stone; and in the extensive assortment of useful subjects prepared in Rosher's patent stone, window boxes are plentiful, various, and beautiful. As compared with the best of these things, however, Messrs. Barr and Sugden's glass cases are pre-eminently beautiful and useful, and the advantage of forming in them permanent miniature gardens is a special recommendation of them for invalids, and for all, indeed, who delight in adding to the elegancies and attractions of home. Light and air are precious gifts, and no plant-cases should ever interfere with the free admission of two such health-giving agencies to dwelling-rooms; but where the window plant-case can be adopted without interfering with light and ventilation, there can scarcely be a better way of increasing the elegant resources of town life.

THE MANGO IN MADEIRA.—Mango trees are now become common in Madeira, and produce fruit abundantly when they have once come into bearing, which is not till they are ten years old or more. The oval or roundish-oval yellow fruit (ripe in September or October) abounds in rich juice like a nectarine, but has always somewhat more or less of a resinous or carrot-like flavour. The flowers are fragrant, like mignonette. The mango is scarcely ever seen in the Canaries, and but rarely in the Cape Verde.—R. T. LOWE, in "*Royal Horticultural Society's Journal*."

ARTICHOKES.—A horticulturist of the environs of Nantes is said to have discovered a method of producing artichokes of enormous size. When the fruit is formed and has attained the size of an egg, he makes a deep incision in the stalk, which lets the sap flow out, and prevents it from reaching the fruit. Under these conditions the artichoke reaches very unusual dimensions. He has also found means to give to all the leaves the qualities generally possessed only by the innermost, by simply covering the plant with a dark cloth to protect it from the sun.—*Galignani*.

THE HARVEST HAS COMMENCED in a few favoured spots in the south of England, and in Bedfordshire, peas, rye, and barley have been largely cut. Wheat generally looks well, though the plant is thin, and in many tracts of country in midland and southern parts has been much injured by the tremendous rain of the 26th. Turnips are growing vigorously, mangolds are making up for lost time, and the potato crop promises to be abundant and good. Reports of disease have been rife; but if it has really occurred at all, it has been quite local and partial.

A NEW GREEN FOR CONFECTIONERY, perfectly innocuous, may be thus formed:—Infuse for twenty-four hours 0.32 gramme of saffron in 7 grammes of distilled water; then take 0.26 gramme of carmine of indigo, and infuse it in the same manner in 15.60 of distilled water. By mixing the two liquids a large quantity of a beautiful, strong, green dye may be obtained. Ten grammes of this solution will colour 1,000 grammes of sugar. This dye may be kept for a long time by evaporating the liquor to dryness or transforming it into a syrup. The most beautiful green colour now used is formed by the dangerous preparations of copper or arsenic.—*Journal de Pharmacie*.

THE BELGIANS' BOUQUET.—They say that the magnificent bouquet of flowers from Ghent, which the Belgian volunteers presented to Miss Burdett Coutts, was composed entirely of hothouse flowers, as illustrative of the warm reception they had met with at Holly Lodge.—*Echoes of the Clubs*.

THE HALL OF OMNISCIENCE.—They say that big things are not always great ones; and that the Kensington Hall of Science and the *Great Eastern* are two of the most striking illustrations of the axiom. Mr. Boucicault, in proving that no human voice could fill such an area as the Great Hall of Science, which is eleven times greater than that of Covent Garden Theatre, seems to prove at the same time that it will be equally difficult to fill the space with an audience, inasmuch as few listeners would be tempted to go to hear nothing.—*Echoes of the Clubs*.

CITY RENTALS.—The *City Press* states that during the last ten years the annual rental of the City property has increased 273 per cent., or a million and a half sterling. The houses in 1811 were worth 32*l.* per house annual value; they are now worth 137*l.* They were worth, to capitalize them at twenty-five years' purchase, in 1811, 14,131,075*l.*; they are now worth, by the same process, 52,784,375*l.*, equal to the total revenue of Great Britain only a few years since, and equal to five-sixths of the present revenue.

PETERBOROUGH HORTICULTURAL SHOW.

The second exhibition of the Peterborough Society was held on Thursday, the 25th of July, in a field adjoining the cathedral. The spot was well chosen, both for its immediate proximity to the busiest parts of the town, and the beautiful surroundings of noble architecture and fine trees by which it is favoured. The several classes of productions were grouped in four tents, the most attractive being those in the general and amateurs' tents; but the cottagers' collection was interesting, and comprised many skillfully grown plants and flowers. The weather was delightfully fine, and the inhabitants of Peterborough and the country round honoured the labours that had been incurred for their gratification by crowding the tents from a very short time after the public were admitted. The classes for stove and greenhouse plants in the general section were well filled, Messrs. Wood and Ingram, of Huntingdon, leading the way with handsome specimens of plants in flower and plants with fine foliage. Mr. Davie, gardener to Lord Huntly, put up some good Gloxinias; and Messrs. Wood and Ingram Gloxinias and Achimenes. Caladiums were not good; it is, in fact, getting late in the season for them. Some of the best Fuchsias ever seen at a show were put up by Mr. Davie; they were not remarkable for size, but they were perfect in symmetry, and literally loaded with flowers. Those from Mr. House, of the Eastgate Nursery, Peterborough, were fine plants, surpassing Mr. Davie's in size, but not in finish. Pelargoniums of all kinds were well shown, Mr. House, Messrs. Casbon, Mr. Atherton, Messrs. Wood and Ingram, and Mr. Ewart being the winners. In several instances small, bright, well-trained plants took the favour of the judges before larger and showier specimens wanting training, which stood beside them, to the surprise of many of the visitors. In one instance this was strikingly the case; for Mr. House presented a group of huge plants with abundance of bloom, which if trained in good time would have stood first without a question, but they were placed second to neat specimens that were unique in style of training, yet not a stick or tie visible, and every leaf and flower in its place, and all as fresh as the morning. The tricolors in this class were good, and there was a fine plant of Lady Cullum in one group, showing the fine red zone and high golden ground for which it has become justly celebrated. The zonals generally were good sorts, and it is agreeable to record that quality in this class is appreciated at Peterborough. The Petunias from Mr. House were admirably done—dwarf, stout, leafy, flowery plants; we see so many lean examples of these at country shows, that a variation in the direction of good culture is worth recording. In the classes for cut flowers, Messrs. Wood and Ingram put up fine collections of Carnations and Picotees; Mr. Draycott and Messrs. Casbon, Verbenas, the first particularly good. Six Gladioli were shown by Mr. Atherton; they were good, considering the time of year, but would not compare favourably with average samples later in the season. Messrs. Casbon showed good Hollyhocks in spikes, which is the only satisfactory way of showing them, though as cut flowers they are attractive and pleasing. The competition in Roses was spirited and close, Messrs. Paul and Son, of Cheshunt, and Mr. Draycott running a nearly even race, but the Cheshunt firm made the winning, and Mr. Draycott was a good second. Mr. Lawrence, Messrs. Wood and Ingram, Mr. House, Mr. Laxton, Messrs. Casbon, and Mr. Atherton also competed. New Roses were best shown by Mr. Draycott; Messrs. Paul and Son second. Here were good examples of Exposition de Brie, Abel Grand, Alfred Colomb, Comtesse de Jaucourt, Thorin, and others of good quality. Messrs. Paul and Son were first for Teas and Noisettes, which were shown in a separate class; and though the flowers were beautiful, they were not effective: they required to be grouped for effect with high-coloured roses, to bring out their qualities. The best mixed group of plants came from Mr. House.

In the general class for fruit, Mr. Davie contributed magnificent samples of black grapes, Mr. House and Mr. Spragg following honourably; the two last-named exhibitors also showed good samples of white grapes. Peaches and nectarines from Mr. House were fine, and the last-named put up the best collection of fruit. Of other fruits there were many good dishes; indeed, the fruit department was one of the most satisfactory.

The amateurs' tent was well furnished, the best group of stove and greenhouse plants came from Mr. James Ewart; second, Dr. Porter; third, Rev. W. R. Thomas. In the class for fine-foliage plants, the awards were in the same order. Dr. Porter sent the best Gloxinias; Rev. W. R. Thomas second. There was a large competition in the class for exotic ferns; all the groups contained good plants, but none of them were equally good throughout. The first prize went to Mr. J. Ewart; second, Mr. J. Whitwell. Very pretty groups were also contributed by Mrs. Whyley, Dr. Porter, and Mr. J. Thompson. As it may interest the cultivators of the district to know on what principle the first prize was awarded, the judges made a note to the effect that Mr. Ewart's plants of *Nothochlæna nivea* and the crested variety of *Pteris serrulata* were especially meritorious though small, and the other plants in the group were equal in merit to any others competing against them. A good *Nothochlæna nivea* will fairly count for two or three in such a competition, as it is a difficult fern to grow to a size fit for exhibition. The class for hardy ferns was also well filled, and the plants were required to be correctly named. The first prize group, from Mr. Whitwell, comprised many rare kinds in a good condition, with plenty of well-grown plants of popular and vigorous-habited varieties. The judges examined the names of all the plants in this class, and found in the first lot only two incorrect labels out of about two dozen plants, and those were not very bad—such, for

example as "*Adiantum nigrum*," instead of *Asplenium adiantum nigrum*. Second in this class, Mrs. Whyley. Miss Leeds presented a pretty group of plants. In the class for Solaginellas, Dr. Porter took a decided first position, having good plants, two of which were variegated varieties. The gold-tipped *S. denticulata* in this group was exceedingly pretty. The Rev. W. R. Thomas presented an interesting group, which was most deservedly placed second. The Begonias from Mr. Ewart were first-rate, —better leaves could not be desired, but the plants were, comparatively speaking, small. The Rev. W. R. Thomas contributed a very effective group. Achimines were not good, but the best came from Dr. Porter. Fuchsias were admirably shown by Mr. Ewart, Mr. J. Thompson, Rev. W. R. Thomas, and Rev. — Grsy. Other classes were equally well filled and equally satisfactory. A fine Oleander, five feet high, leafy to the bottom, and well covered with beautiful flowers, won for its owner, Mr. J. Thompson, an extra prize, and was well worth it; for, usually, as Oleanders increase in size they decline in beauty. Cut flowers were not good throughout in this section, but some beautiful roses were shown by Messrs. Laxton, Fryer, Rev. R. S. C. Blacker, Dr. Porter, and T. Macanlay. Dahlias from Mr. Fryer were good, and Dr. Porter sent a group of Gladioli which were of good quality, considering their earliness.

A very interesting feature of this exhibition was the competition of ladies in dinner-table decorations and bouquets. Mrs. Porter took the first place in decorations in a very decisive manner, with a plateau richly decorated with fruit. It was surmounted by a silver nautilus-shell filled with flowers. We thought the silver stand and shell the least meritorious part of the construction, the shape of the shell not being well adapted either to display or preserve the flowers; yet it was in its way beautiful, and the *tout ensemble* was at once novel, rich, tasteful, appropriate, and pleasing. Miss Leeds took second place with a group of glass épergnes of the well-known March pattern. They were too much crowded with flowers, and there was no special touch of grace about them to give finish; fewer flowers and more green would have greatly improved them. Mrs. Hopkinson and Miss B. T. Saunders also contributed. In the class for bouquets the contributions were numerous and good, but the bouquet from Mrs. Macaulay quite distanced them all in its freshness and delicacy of colouring, pink and white with a few small dots of blue, with a fringe of fresh fern-leaves constituting its elements, and quite defying description. For this was awarded the five-guinea cup most deservedly. For once in our time we can say we have seen a perfect bouquet. Miss Bland took the first prize in the money classes, G. Copley second. One fair competitor had adopted the *Land and Water* theory of complementary colours, presenting a bunch of flowers arranged in rings of red, white, and yellow, a sort of small flower-bed of the road-side garden type. Gallantry forbids us to condemn, but, as fair reporting is proper, we will respectfully suggest to our lady readers that they need not trouble themselves at all about the complementary theory, and in saying that we desire to be complimentary ourselves, having deeply at heart the increase of their enjoyments in the grouping of flowers.

In the fruit department special mention must be made of the well-grown fruit-trees in pots from the Rev. W. R. Thomas; for though they were much brushed by the company, owing to the position they were placed in, they showed to the last that they had had the care of a skilful cultivator.

In the cottagers's section the contributions were generally good, and in many instances remarkably so. We regret we cannot afford space to do them justice.

Messrs. F. and A. Smith, of Dulwich, presented a collection of their beautiful new varieties of gold and silver zonal pelargoniums (tricolor geraniums), which were greatly and deservedly admired. First-class certificates were awarded them for *Jetty Lacy* and *King of Tricolors*. Mr. Watson, of St. Albans, exhibited a collection of three varieties of the same, and obtained a first-class certificate for *Mrs. Dix*. Mr. Burlingham and Mr. Paviour, watch and clock makers, of Peterborough, made a large and attractive display of table decorations, flower glasses, vases, &c., &c., executed both in glass and metal. This part of the exhibition was eminently interesting.

To the promoters of this show, and especially to Dr. Porter, the Rev. W. R. Thomas, and W. D. Gaches, Esq., the honorary secretaries, the highest praise is due for the general arrangement, and for the measures taken to secure full justice to every class of exhibitors. Nor can we omit to mention that Mr. House contributed largely from his well-furnished nursery, and this without respect to the schedule—for the good of the cause, in fact, and not for his own good. He capped his labours by providing a luncheon for the judges. May the House last long that holds his generous nature! The judges were Mr. Pearson, of Chilwell; Mr. F. Smith, of the Dulwich Nurseries; Mr. Clarke, of Studley Royal, Ripon; Mr. Roberts, Mr. B. Taylor, Mr. Casbon, and Mr. Sbirley Hibberd.

THE BEDDING DISPLAY AT THE CRYSTAL PALACE.

That our annual reports on bedding should be delayed to so late a date is simply the consequence of the coldness and the general unkindness of the season. The weather has offered some practical commentaries on our essays upon the increasing necessity for hardy plants, and upon the relative merits of the plunging system. Every word that has been offered in these pages on the difficulties, expense, and uncertainties of the bedding system, and on the advantages resulting from a liberal recognition of the merits of hardy plants, has been illustrated by the events of this season. We were enjoying displays of bedding plants by the plunging system in the middle of May, and were then praising the beauties of the Pyrethrums and other May flowers that have places in well-kept gardens, and that no bad weather can do hurt to; yet on the 1st of July the bedding at the Crystal Palace was not quite completed, and the planting accomplished by that date was far from being gay with flowers. Mr. Gordon had been fighting with the elements, and of course had got worsted in the battle. The Crystal Palace gardens were in no respect in arrear of other gardens similarly situated; and in these remarks we simply select them as the best known examples for purposes of comparison, and to point the conclusion, that whoever practises bedding extensively must expect to be without flowers in the very pink and prime of the whole year, the months of May and June. Of course, these gardens are gay enough now, magnificently so; the bedders are right at last, and the splendour of the colours during August and September may amply justify the excessive labour and the great expenditure of money and time required to produce it. For a great place of general public resort, there can be no doubt that an elaborate display of bedding is most proper and desirable; but it is a sad mistake

when a lady or gentleman owning a small demesne expects grapes and flowers and bedding plants all from a small extent of glass, and considers the gardener incompetent because his out-door display does not equal or surpass that at the Crystal Palace. The fact is, the Sydenham bedding is not adapted for imitation in small private gardens. It is promenade work, and admirably suited for the entertainment of crowds; but it would soon tire all the crowds that now rejoice in it were the individuals, each and all, to be compelled to behold it daily during its season of magnificence. But while we regard it as matter for regret that many possessors of private gardens consider themselves bound to imitate the Crystal Palace bedding, we cannot for a moment forget that here is one of the best out-door schools of design for gardeners of all classes, amateur and professional. The practitioner who can walk over these grounds, and not obtain a hint or idea of some practical value, must need to be taught the use of his eyes. And not only may we learn here something about design and colour, but we may find examples of all the best bedding plants, new and old, and make useful notes on the subjects most likely to be useful to ourselves. A large number of amateurs residing near the metropolis, and indeed a large number who dwell far away, make a point of visiting the gardens at Sydenham every year, with this sheet in their hands, for the purpose of comparing varieties, noting distinctive effects of contrast and harmony, and otherwise checking, correcting, and improving their own schemes of out-door embellishment. To all such we can say that, though Mr. Gordon has had unusual difficulties to contend with, the Sydenham bedding is rich and satisfactory this year, and well worth inspection by practical men, no less than by the thousands of mere sight-seers, who are not very critical, provided they see plenty of colour.

This time we will take our stand at the top of the central flight of steps in front of the principal garden entrance. From this position we see the whole of the terrace colouring,—the Araucarias with their circles of blue and silver in the foreground, the bold line of colour which forms the string of the bow immediately at our feet, or, in other words, the chord-line of the great semicircle which constitutes the central block of the second terrace. Farther away, right and left, the wing blocks are seen to be in a different style to the centre, drawing out the vast pattern to its proper dimensions, and at the greatest distance revealing clearly the general purport of the design. Usually distance makes a muddle of a bedding display, but here it is not so; the space is so extensive that the patterns can be made large enough to show their lineaments when viewed from this central point, and the large use of gray, yellow, and pink in the outermost schemes gives them a sharpness and distinctness that would be wanting were they coloured in the same rich manner as the central compartment. If the reader will refer to the figures of the principal or second terrace at pp. 318 and 319 of last year's GARDENER'S MAGAZINE (July 14, 1866), it will be seen that the great central semicircular compartment (D, D, S, p. 319) is embellished on its upper or bow side with a line of Araucarias and pedestals alternating. It has always been the custom to plant round these, the trees having circles of Lobelias and Cerastium, the pedestals circles of geraniums. It is one of the special delights of a view of the garden from the first or upper terrace to look down on these circles, so distinct and beautiful are they in their regular alternation of scarlet and blue, with gray in each case to afford distinctness to the outlines. The planting of these circles may all be read off from the top of the steps by persons familiar with bedding and bedding plants; but as this report is intended for the use of the world at large, we must say that the Araucarias are planted alternately with Lobelia Paxtoniana and Cerastium tomentosum, and Lobelia Blue King and Cerastium tomentosum. It is not needful to go through the series, but the reader may do so without difficulty; and the planting of the pedestals will be found to be, on the north side, thus—One row of Alma outside, four rows of Stella, one row of Alma inside: one row of Alma, four rows Christine, one row Alma: one row Alma, four rows Crystal Palace, one row Alma. On the south side, that is to say, the southern half of the great semicircle, Flower of the Day takes the place of Alma, but otherwise the planting is the same.

Let us now go down to the chord-line, where the grandest display in the whole garden is presented to us. Here we have a series of circles and oblongs, forming a flower border next the main cross-walk, 680 feet in length. In the planting of this border the artist must be bold and decisive, and he must content himself with about half a dozen varieties of plants, for if he attempts the least complication failure is certain. It will be agreed by all that Mr. Gordon has added to his long list of triumphs in the colouring adopted here in 1867, for here is richness with perfect harmony, and decision with boldness, but without lack of refinement in the tone. The circles are edged with Flower of the Day, next within are two rows of Christine, the centre is Trentham Rose. The oblongs are edged with one row of Purple King verbena, next within that one row of Flower of the Day; next within, two rows of Gaines's Yellow Calceolaria; the central line consists of three rows of Stella. Viewing the planting ribbon-wise, it will be observed that the intense deep colouring of Stella is interrupted by the lighter and brighter tones of Trentham Rose and Christine, and the effect is a rich mixture of reds in the centre line, and on each side a yellow line is interrupted by lengths of gray. It will bear inspection more than once, and that from several different points of view. In criticising this arrangement I went northward, and, when at the extreme north end of the 680 feet length of colour, turned sharp round to return to the central steps by way of the semicircle, to which the pedestals and Araucarias form the boundary on one side; on the other side of the walk are circular and oblong beds, the positions of which are indicated by letters H H in the figure at page 319 of last year. We are now dealing with the northern crescent, that is to say, the right-hand H in the figure. The first bed on the way up from the great cross-walk is edged with Silver Queen, and the remainder is a solid block of Tropæolum Perfection, a very fine scarlet bedder. The next bed is edged with Flower of the Day, and the body of the bed consists of Crystal Palace Gem and Lobelia speciosa, plant and plant. This Crystal Palace Gem is one of the favourites of our Geranium papers: here you may see it and judge for yourselves. The next bed is edged with Lady Plymouth, and the body of the bed is geranium Fatanizzi: this last is an old favourite here, and a very good bedder of the salmon coloured section. The next bed is edged with Centaurea ragusina, and has a solid block of Amaranthus melancholicus. The next bed consists of Sottesbam Pet and Lobelia Blue King; no note made of the edging. The next is edged with one row of Silver Queen, and within that is a solid block of Excellent. The next is one row of Lady Plymouth for edging, and within that a block of Mrs. Pollock. Now our course is broken by a compartment of rhododendrons, next we pass the grand steps, next a companion clump of rhododendrons, and then

go on again the beds on the southern crescent, or the left-hand H in the figure at page 319 of last year. The first bed here corresponds with the last one; it is a circle edged with Lady Plymouth and filled in with Mrs. Pollock solid. Next, one Silver Queen and block of Excellent. Next, row and row alternating of Shottesham Pet and Blue King; no note of the edge. Next, edging of *Centaurea ragusina*, and block of *Amaranthus melancholicus*. Next, Lady Plymouth edge, and block of *Fatanizzi*. Next, one row of Alma, the filling-in consisting of Crystal Palace Gem and *Lobelia apiciosa*. The last in the series is the same as the first in the former, being, like it, a corner bed, at the junction of the crescent with the cross-walk, edge Silver Queen, filling-in *Tropæolum Perfection*.

We may now conveniently inspect the chain pattern in the compartment to which our attention has been partially directed while inspecting the beds last described. This compartment continues the line of the main cross-walk on one side (see K in figure at page 318 of last year), and opens the way to the flight of steps immediately contiguous to the ethnological department. The corresponding compartment flanks the cross-walk, and opens the way to a similar flight of steps near the north wing. Both compartments are planted the same, of course, and the description of one will suffice. At the corners are large blocks of shrubs, embraced by the heart-shaped beds which at these corners form the outermost parts of the chain. These heart-shaped beds consist of two rows of Crystal Palace Geranium and a block of *Gaines's Yellow Calceolaria*. On either side of the heart-shaped beds are circles, consisting of two rows of Christine and central block of *Perilla Nankinensis*. Beyond these again are oblong beds, which are planted the same as the corners. All are connected together by means of links, consisting of the well-known variegated *Alyssum*, and this goes round all the beds, and forms an edging to the whole.

There are many hits of colouring that we take no notice of, for the simple reason that it is impossible to describe every bed in such a place as this, and it would be of no use to describe schemes that cannot be easily discovered. But mention must be made of a bed comprising two meritorious novelties. We are now near the steps which lead to the first-class dining-room. The position is marked by the letter M in the large print at page 318 of last year. The last bed but one next the main cross-walk (L) at this point consists of one row of Cloth-of-Gold, two rows of Crystal Palace Rose, and centre block of *Duchess of Sutherland*, the last being one of the new nosegays specially recommended in the Geranium papers.

We may now deal with the two outermost compartments (L at page 318 E at page 319, of last year). There are four corner panels in each of these compartments, very prettily planted. The edge is *Gnaphalium lanatum*; next, two rows of *Gaines's Yellow Calceolaria*; at each end a circle consisting of *Trentham Rose*; the filling-in consisting of *Cottage Maid*. The slope next the railway corridor has a series of beds that are usually described as *Vandykes*, which is incorrect. Our figure will show that the idea is much more probably taken from a well-known feature in architecture. In former reports we have described them as resembling a series of medals connected with loops of ribbon, but such a description will scarcely suffice this season; for the style of planting adopted destroys the medal completely. Those who are curious enough to go so far in their inspection, will find the planting to consist of *Lobelia Paxtoniana*; next, one row of *Flower of the Day*; next, two rows of Christine; the centre, *Perilla*; at the north end, flanking the orangery, *Cryal Palace Scarlet* is put for Christine.

It will now be convenient to go to the Rose Mount. The ground-plan of the mount and its surroundings will be found at page 328 of last year's volume (July 21, 1866). There are six walks up, with large V-shaped beds at the corners, and circular beds right and left. We usually begin here with the walk nearest to the railway station, marked A on the plan just referred to, where the great V-bed consists of a centre of *Stella*, with two rows of *Gaines's Yellow Calceolaria* on each side, and an edging of *Flower of the Day*. This bed will serve to give the key to our course, so that those readers who take the book with them will have no difficulty in finding their way to whatever else is to be described. Before starting, however, it seems proper to call attention to one of the circular beds, which is conspicuous for its colouring, and is as nearly as possible situated exactly opposite the ticket wicket, where the garden is entered from the railway station. This is a circular bed, consisting of Mrs. Pollock, edged with *Alternanthera spathulata*. Let us now go up this walk, to have a look at the pavilion. The roses are over, or nearly so; but there is a good promise of a second bloom. The slope or *glacis* immediately surrounding the pavilion is extremely gay, and this year is planted in a series of festoons enclosing escutcheons. All along the top line is *Cottage Maid*; next below it are escutcheons of *Trentham Rose*, divided by festoons of *Coleus Verschaffeltii*. Below these are festoons of *Flower of the Day* and Christine, one semicircle of each repeated, and every semicircle enclosing an escutcheon of *Purple King verbenæ*. In the spaces between these last loops or festoons, on the lower side, are blocks or escutcheons of *Tagetes signata pumila*, the now well-known dwarf yellow marigold, which in many places has taken the place of *calceolarias*. The boundary on the lower side is a continuous fillet of *Blue King Lobelia*. This is very gay, rather novel, and tasteful in the highest degree: it is to be hoped the marigold will hold out to the end of the season. In the centre of the pavilion the beds in which the gey-ropes of the flag-staff are placed consist of an edging of *Shottesham Pet*, two rows of Christine, and centre of *Stella*. From these we naturally turn to the six sunk panels, which are planted as three pairs, each bed having its counterpart on the opposite side. One pair of panels consists of two rows of *Tagetes signata pumila*, two rows of Christine, and centre block of *Stella*. Another pair consists of edging of variegated *Ageratum*, three rows of *Cryal Palace Scarlet*, centre block of *Gaines's Yellow Calceolaria*. The remaining pair consist of edging of *Gnaphalium lanatum*, two rows of *Calceolaria amplexicaulis*, central block of *Cottage Maid*. Let us now go down by the same walk as we came up—that is, towards the railway station (A in the figure at page 328 of last year).

Going down from the pavilion by this walk, we have on the left a bed consisting of one row *Shottesham Pot*, filled in with *Brilliant*; this is very effective. The match to it on the right is *Stella*, edged with *Shottesham Pet*. Next down on left, a seedling *Lobelia* of Mr. Gordon's, not yet named, forming the edge; next, two rows of *Geranium Diamedatum erubescens*, filled in with *Fatanizzi*. This new *Lobelia* is of exceedingly dwarf compact habit; the colour a clear deep azure blue. A good name for it would be *Blue Cushion* or *Sapphire*, but Mr. Gordon has not determined yet what its name shall be. The match bed to this is of the same *Lobelia*, with two rows of *Geranium Countess of Devon* and a centre of

Sidonie. This brings us to the V-bed with which we began, and there will perhaps be no harm in repeating that it consists of one row of *Flower of the Day*, two rows of *Gaines's Yellow*, and centre block of *Stella*.

The circle on the right, exactly opposite the V-bed, consists of an edging of *Geranium Silver Queen*, filled in with *Tropæolum Perfection*, a capital small-growing scarlet. Next on the right, the bed previously referred to, in which *Alternanthera versicolor* figures for an edging, the remainder of the bed being *Mrs. Pollock*. The next circle on the right has for an edging the new *Lobelia*; next, two rows of *Centaurea ragusina*, and centre of *Coleus Verschaffeltii*. Going on to the right, we have a bed edged with *Beaton's Minimum Pink Nosegay*, a curious variety, with yellowish green leaf and reddish brown zone and pink flowers. The remainder of the bed consists of *Excellent*.

The next V-shaped corner bed (marked B on the sketch) has an edging of *Cloth-of-Gold*, two rows of Christine, centre block of *Crystal Palace*. On the way up, we have on the left an edging of *Smith's Light Fancy*, and centre of *Prince of Orange*.

Further on we have a pair of beds, the left being *Lady Plymouth*, and *Blue King Lobelia*, the match to it being *Variegated Prince of Orange*, and a seedling blue *Lobelia*; a very pretty one too, the blue being of a deep clear tone, the centre of the flower pure white. The top bed is an odd one; it consists of edging of two rows of *Harry Hicover*, filled in with *Madame Vaucher*, which has not shown a white flower all the season, but plenty of a nice blush. We go down again and meet with one circular bed not seen before, consisting of an edging of one row *Mrs. Pollock*, next two rows of *Sidonie*, filled in with another new and interesting nosegay, *Lady Constance Grosvenor*.

The great corner bed at this point projects beyond the true periphery of the scheme, in order to carry forward the route to the Palace, as shown by the arrow at G on the plan. This bed has for edging *Viola cornuta*, next one row of Alma, and within these a fine block of *Lord Palmerston*. We now head round to the right, and find our way to the next V-bed, shown at D on the plan. This has for edging one row of *Gnaphalium lanatum*, two rows of *Gaines's Yellow*, and a central block of *Trentham Rose*. Once more we go up towards the pavilion, and find on the left a bed edged with white *Lobelia*, next two rows of the new yellow-leaved *Iresene aureo-reticulata*, enclosing a block of *Iresene Herbstii*. Next on the way up, and still on the left, edging of *Nierembergia gracilis*, filled in with *Heliotrope corymbosa*. Again on the left going up, edging of *Lobelia Paxtoniana*, with block of *Geranium Countess of Devon*. The match to this on the right is *Lobelia speciosa*, enclosing a block of *Geranium Gipsey Queen*. The top pair consists of left-hand bed of *Silver Queen* edge, enclosing *Comte de Morny*, and right-hand bed of *Silver Queen*, enclosing *Lady Mary Fox*. Now, down again, and pass all that we have just described. The next beyond them on the right has an edging of *Arctotis repens*, enclosing a block of *Gazania splendens*. The next is edged with *Harry Hicover*, with block of a seedling geranium with rose-pink flowers, a truly splendid bedder, and of a class in which improvement is needed. The next is edged with *Shottesham Pet*, enclosing a block of *Tropæolum Perfection*, a splendid bit of colour. Once more we arrive at a great corner bed, the one marked E on the plan.

If we look to the left, that is, away from the Mount, we see a triangular compartment with *Wellingtonia*, and three large triangular beds. These are planted with an edging of *Gnaphalium lanatum*, two rows of *Crystal Palace geranium*, the centre *Lucius*. The V-shaped bed (marked E on the plan) which occurs in the usual place at the next walk up, has for edging one row *Purple King verbenæ*, next two rows of Christine, centre block of *Cottage Maid*. On the way up, on the left, an odd bed edged with *Crystal Palace Gem* geranium, the one of F. & A. Smith's aforesaid, and which had a leading place in the Geranium papers last year as a first-class golden-leaved variety. The centre block consists of *Madame Vaucher*. The next beds are a pair; that on the left consists of *Lobelia apiciosa* and *Shottesham Pet*, plant and plant; that on the right consists of *Blue King Lobelia* and *Cloth-of-Gold* geranium, plant and plant; both good beds, but not well matched. Again, a pair, the left being *Lobelia speciosa* edge; next, a ring of *Centaurea ragusina*, and a block of *Amaranthus melancholicus*. The right-hand bed is edged with two rows of *Lobelia speciosa*, two rows of *Centaurea ragusina*, and block of *Perilla*. These are not a good match. Now we go down again and wheel to the right, and passing the beds already scanned, we come to one with *Dandy* edging and block of *Excellent*. The next is edged with two rows of *Tropæolum compactum luteum*, with block of *Tropæolum compactum coccineum*. Here speculative amateurs not yet acquainted with them may form some opinion of the merits of Mr. George's series of *Compactum Tropæolum*. The next is edged with one row *Gnaphalium lanatum*, and within that *Verbena venosa* and *Cinoraria maritima* in alternate circles; a curious bed decidedly, and a change from things commonplace. The next is edged with *Japanese honeysuckle*, and the centre block is *Salvia patens*. The last in this series is a bed of *Prince of Orange*, edging not planted when these notes were made.

The next corner or V-shaped bed (F in the figure) consists of an edging of *Nepeta violacea*, the pretty blue-flowered *Salvia*-like plant we have so frequently recommended, and which is sometimes described as *Salvia chamædrifolia*; within the edging two rows of *Gaines's Yellow Calceolaria*, and a fine central block of *Cybister*. Again we turn to the right, and up. On the left, the first bed is edged with *Shottesham Pet*, enclosing a block of *Tropæolum Perfection*. To the right is a match bed with the same edging, and a seedling *Tropæolum* called *Gipsey King*, a fine dark variety. The top pair consists of left-hand bed of one row of *Cloth-of-Gold*, enclosing a block of *Purple Nosegay*, or *Fothergillii*, the right being one *Cloth-of-Gold* and block of *Lord Palmerston*. We now go down again and pass five beds, which were not planted when these notes were made, and which we hope may be spared from the report. So we come to another great triangle, the one marked G on the plan.

This last of the V-shaped beds is edged with two rows of the little marigold *Tagetes signata pumila*, next one row of *Brilliant*, centre block of *Purple Nosegay*. On the way up a pair of beds consisting of edging of *Golden Chain*, two rows of *Excellent*, and block of *St. Clair*. At this point we close the description of the Mount. Our notes were made on the 29th of June, with a view to publication of this report in the week following. We have kept it back till now, hoping to be enabled to make another visit, but other engagements have prevented us, and it seems better to make the best of the notes as they are than to delay any longer their publication.

There remains yet one magnificent piece of planting, the description of which will require but few words; but every student of these matters must

see it. As a matter of necessity, almost all visitors to those gardens on grand days do see it, for it is the series of oblong and circular beds which flank the main walk on each side on the way from the terraces to the fountains. Yet, important as the situation of these beds may be, few people, comparatively, out of the thousands who visit the Crystal Palace during the season see them; for when they get to the central walk which divides the upper garden into two equal parts, at the intersection of the great basin and the water temples, it does not occur to them to look over the parapet and down upon the beds. Those who have ever done so will doubtless be in haste to know how those beds are planted this season. The oblong beds here are each 30 feet long and 9 feet wide, and the circles are 9 feet wide to correspond with the others, and the first series extends about 350 feet. The long beds have an edging of *Geranium Mangle's Variegated*; next two rows of *Christine*; next two rows of *Gaines's Yellow*; next three rows of *Stella*. Ye who can paint all this in your mind's eye, say, is it not grand so far? Now for the circles. These are edged with two rows *Lobelia Paxtoniana*; next, one row *Golden Chain*; next, two rows of *Crystal Palace Scarlet*; and lastly, centre block of *Trentham Rose*. Then we find a bed of *Dahlia's* at the turn round the great basin, and then we go on again as before on the way down to the Temples. Let us suppose, for the sake of convenience, that the fountains are just about to play, and that the visitor, tired of this long story, is on his or her way down to be refreshed; what better can we do than suddenly snap the thread, and abruptly conclude our report on the Crystal Palace for 1867. S. H.

CUCUMBERS FOR THE WINTER.

Having been a successful grower of cucumbers for winter consumption for several years past, I have decided to detail my practice upon paper, and I do so with a hope that it may be useful, feeling that I ought to do something for the pages of the Magazine in return for the many useful hints I have gleaned from a constant perusal of its columns. In the first place, I must remark that the details given below refer to cucumbers grown in houses only, and not to those grown in frames with duug-heat, and I may state that the bottom-heat is furnished by a tank filled with water, through which a 4-inch flow and return pipe is carried, which is heated from the boiler, in conjunction with six other pipes of the same size for top-heat, in a small lean-to house, 16 feet by 10. I have full control over all the pipes, and only use those for top-heat when the weather is severe, and I wish to maintain a regular temperature for fruiting plants. And on this depends much of the success; for where there is a deficiency of heating surface the plants suffer materially in frosty weather if they are allowed to get chilled.

The soil I use is a sweet turfy loam, half decomposed leaf-soil, and well rotted dung, in equal parts. To every barrow-load of this I add about a gallon of coarse sand—either river or road sand is the best, as its particles are larger, and consequently they make the soil more porous. I do not like to use for winter work a loam that is destitute of its turfy surface, as it tends to make the bed too close and impervious to air and water. After the bed has been made up a few weeks, therefore, I procure a thin surface spit from which the turf has not been removed. When this has lain by for a few months, it cuts up with the spade in excellent condition. I cut it into pieces about half the size of one's hand, and well incorporate it with the other ingredients. It would surprise those who advocate the growing of winter cucumbers in a soil consisting chiefly of peat earth to see what luxuriant foliage they make, and how vigorously the roots ramify and extend themselves in and around these turfy lumps, and its nature gives to the other component parts an agreeable consistency, while its turfy texture admits of a free access to air and water, without which the plants cannot long remain in health. The rotten dung and half-decomposed leaves are both essential; the first to afford the roots a sufficient amount of nourishment, and the latter are valuable for the organic matter which they contain, and on which the plants will feed with avidity, and show their gratitude by exposing to the cultivator well developed foliage of the densest dark green, such as every good grower of cucumbers delights to see, and without which a satisfactory produce cannot be expected. The above compost should be put on the tank in a moderately moist but not in a wet condition.

As to the time of planting, many years' experience convinces me that it should not be delayed after the third week in August. Of course, they may be planted later and made to fruit during the winter; but requiring cucumbers from December onwards, which we do, I have never yet succeeded in getting a vigorous constitutioned plant when put out after the above time. When planted early, they have time to make a good growth before winter without the aid of fire-heat; and when plants furnish themselves well over the trellis under such conditions, I find they are much less liable to feel the effects of a varying temperature in the after management, as, not being coddled up in the first stages of their growth, they are more hardy, and will endure a certain amount of excitement without injury.

Among many Kentish gardeners, I find that struck cuttings from favourite varieties are generally considered the best for winter work, but for myself, unless I have some special sort I wish to increase or cultivate for the winter, I find seedling plants answer every pur-

pose, and, indeed, they are less liable to come to premature decay than plants from cuttings, as I have before now seen a whole house of cucumbers drop their leaves and wither up in a day during sultry weather in July, yet with no fault in the management. I have never seen the same with plants raised from seed. Whether they ever go off so suddenly I cannot say.

I must now deal with the planting, and whether the plants are from seed or cuttings the remarks will apply. Presuming that the plants are ready, the house thoroughly cleansed from all dirt, the paint all scrubbed, and the glass well cleaned, and the soil being in its place for some days, with the boiler and hot-water pipes in good repair, we may plant with a reasonable hope of success, if there is no break-down with the boiler and no steaming of the plants. Put the plants in the soil, with only just a gentle pressure round each. A small supply of water may be given at this time to settle the soil down to the roots. I prefer to plant of an evening, and then shade for the next two days, not longer, and not then unless it is very bright, as I always like to inure my plants to full exposure to the sun in all their stages, as it gives them a greater power of endurance against any other little vicissitudes that may happen. When cucumbers in houses flag, it is caused either by a weak constitution or for the want of water, or for the want of a judicious system of air-giving. Reader, remember this, and work out the rule until I can spare time to write the remaining portion of my management for an early number.

A KENTISH GARDENER.

NOTES ON SOME BEDDERS.

As usual, a great many new bedding plants were put out for trial in the borders at Stoke Newington in the spring of the present year. I shall not attempt to enumerate them all, or minutely describe the characters of any; but I shall make a few notes on such as have particularly struck me as worthy of a few observations. Many of my long-accustomed readers will remember that my date for many years past for the first start in bedding is the 10th of April. Generally speaking, in sheltered places geraniums and calceolarias that have been wintered dry and cool, and kept very hardy all the spring months, take no harm by being put out so early; and when we had to clothe walls as well as beds, and make pyramids ten to fifteen feet high without mounds of earth for centres, but with plants of the height required, it was very important to begin early, as experience had taught us that five or six degrees of frost did our plants no harm. The plunging system takes the place of bedding now, and whatever we plant out is for trial and comparison. The home garden does not of course suffice for all our practice in this way; but not far away from it we have some good collections, and plenty of work to do. We began planting this season on the 6th of May, a circular bed enclosed by two semicircular borders. The circle consisted of festoons of *Geranium Goldfinch* and *Geranium Mrs. Pollock*, enclosing half-moon-shaped blocks of *Coleus Verschaffeltii*, *Coleus nigricans*, *Iresene Herbstii*, *Alternanthera amœna*, *Alternanthera paronychioides*, *Alternanthera spathulata*, and *Teleianthera versicolor*. The border was planted with festoons of the same kind, but white and creamy-leaved geraniums and *Iresene Herbstii* were the principal features. The object was solely to ascertain how far our bold system of early planting would suit such things. They were all well hardened first, the weather in the latter part of April being quite as good as any we have had since, and much more like summer than any part of the defunct month of July. Everything went well till the 21st of May or thereabouts, and at that time there was a perceptible commencement of growth in the geraniums, which looked as if another week of nice weather would give them a good start. On the 23rd and 24th came a killing frost. I was away at the time, attending the Cambridge show. On the 24th I saw them, and found them slightly altered from the condition they were in when I left home. It must be remembered that the frost referred to was unusually severe. In the field, a furlong or so distant from the home garden, the whole of our collection of 160 varieties of potatoes, then in a forward state of growth, were killed back, with the sole exception of two kinds; and on the spot where these bedders were planted the temperature had twice gone so low as 10° of frost. To prevent any misunderstanding, let it be understood that our minimum register was 22°, just 3° lower than the minimum on the same night at Chiswick. The geraniums looked queer, but were not seriously hurt. The *Alternantheras* (including the *Teleianthera*) were as bright as before, not a leaf hurt; in every respect, so far as we could judge, as good as before the frost occurred. The two varieties of *Coleus* were dreadfully cut about, and some of the plants were quite killed; yet they looked as if, with a little patching and mending, and with downright good weather to follow quickly, they might make a decent appearance at last. As for the *Iresene*, it was literally destroyed. We could find its withered leaves on the ground, but until we looked for

them we might have supposed they had been pulled out of the ground and carried away, so complete was their destruction. From these experiences I conclude that the new *Alternantheras* are well adapted for places where the elements are apt to be unkind to bedding plants. They stood ten degrees of frost without harm, and to learn this much about them is well worth the loss of all the rest. As the scheme of festoons and crescents was ruined, we took up all the *Alternantheras* and potted them for plunging, and put blue *Lobelias* in all the places where the red and purple-leaved plants had been. In the semicircles we made front lines of the variegated *Dactylis*, and gave up all idea of novel colouring.

The mention of the *Dactylis* puts me in mind of the new variegated grass, *Poa trivialis argentea elegans*. It is quite hardy, and grows fast. I took one thin stolon with a scrap of root, or in other words a rooted scrap as thick as a worsted needle, with about five leaves, and potted it in February. It soon began to spread in the warmth of an ordinary green-house. In the first week of April I planted it out, and it now covers a space of ground exactly 20 inches across. In growth it very nearly resembles the *Dactylis*, spreading as that does in the likeness of a mat, but it is not so strikingly white as the *Dactylis*, yet it is more beautiful, for the leaves are narrower and the plant is shy to flower, and when the two are side by side, the *Dactylis* has a coarse appearance. Let it not be supposed I wish the *Dactylis* to suffer by the comparison, for it is one of the most beautiful variegated-leaved bedding plants we have. But the *Poa* is beautiful too and distinct. I have given you its true character, and you can take your choice.

All who have seen the *Golden Feather Pyrethrum*, which is a variety of *Pyrethrum parthenifolium*, at exhibitions have voted in its favour. Several times in the past season Messrs. E. G. Henderson have shown it in quantities in pots, and it has met with general favour. I have not yet seen it planted out any where except here, and I put out one plant so early that it had made a vigorous tuft a foot across before April was out. From that same plant, about the middle of April, we managed to steal a dozen cuttings, all of which were quickly rooted and planted out, and are now nice tufts of sulphur-coloured herbage. It is so good as we have it that I do not believe, in respect of distant effect, there is any geranium to equal it; it is truly brilliant in colour and of neat spreading growth. Where it fails in comparison with geraniums is its lack of individual beauty when looked down upon. Mrs. Pollock, for example, is not very striking when viewed from a distance, but to stand beside a good bed is to see a pavement of jewels, as if Alhambras could be grown to order. The *Golden Feather* will be as good in the golden way, for people who cannot tackle delicate plants, as *Stachys lanata* and *Cerastium* are in the silver way or the milky way; in other words, it is a hardy plant and a poor man's bedder. I had almost forgotten to say that its flowers are worthless, and must be picked off as fast as they appear.

A *Calceolaria* called *Gem* is undoubtedly one of the best for bedding. It is one of the shrubby class, of dwarf compact habit, with flowers of a gold yellow in huge trusses, the habit everything that can be desired and the plant not given to the slight failing of dying the same day as it comes into flower. There are several *calceolarias* bearing the same name, but how to fix the identity of this by its origin I know not, for I am ignorant of its history. Our able and enterprising nurseryman, Mr. Oubridge, of Stoke Newington has it, and no doubt could manufacture a few thousands of it for next season, if ordered now. It is certainly the best in these parts. That is all I can say of it.

Verbenas are plentiful enough, yet there will always be a demand for good bedding varieties, if in any respect in advance of established kinds. *King of Bedders* is first-rate, and whoever has it will be sure to propagate it for next season. To say that it beats Admiral Dundas is not mean praise, for that is certainly one of the best still. But it surpasses the Admiral in colour, being a more brilliant shade of crimson-red; the growth is free and dwarf, not subject to mildew; the flowers are produced in great abundance, the pips and trusses large, and with a fragrance that will revive in high summer the odour of spring violets. I know of none among the *White Verbenas* to equal *White Queen*. It is a pure white, even in the hottest and driest weather. Unfortunately, we have had little of such weather to prove it by this season, though we have had rain enough to wash it away; but it blooms as bravely whether sun or shower. This scarcely requires pegging; indeed, unless in very rich soil, which it does not require, pegging need not be attempted. Mr. Thorpe, of Littlethorpe Gardens, near Leicester, sent us a variety without a name, which has proved to be a first-class bedder. The flowers are large and stout, but not well formed, the trusses of good size; the colour blackish velvety crimson with a touch of violet in the eye. It is incomparably rich, and for a heavy royal sort of bed the very perfection of a verberna.

Tropæolums have become so abundant that there are just five times as many named varieties in cultivation as we require. The *Compactum* series, for which we are indebted to Mr. George, of Stamford Hill, have been better this season than last, the result,

doubtless, of the farther remove of the plants from a seedling state, propagation through several generations by cuttings having apparently improved and refined their natures, and increased their tendency to flower. The four best in the series we have, and for plants of which we are indebted to Mr. Cannell, of Woolwich, and Mr. Kirtland, of Stoke Newington, are *Luteum Improved*, a fine deep orange-yellow with small crimson spots; this is the most robust and free of all; it forms a round compact bush, and flowers without intermission. The next best appears to be *The Moor*, the colour of which is maroon-crimson, apparently the next in order of robustness, and readiness to grow and flower. *Novelty* must perhaps take the next place; this is decidedly diminutive in growth, and the flowers do not expand so flat as in the two just named; the colour is intensely bright orange-scarlet with a few touches of orange. Lastly, *Scarlet Gem* is the weakest grower of all, quite a miniature, and a gem of its kind, for it covers itself with flowers, and these are most neat and beautiful in form, expanding to an almost flat face, the colour being clear light scarlet. The best of all the *Compactum* series are *Luteum Improved*, *The Moor*, and *Scarlet Gem*, the last named being the weakest grower of the three. Since some time early in June, *Tropæolum Advancer*, sent by Mr. Chater, of Gonville Nurseries, Cambridge, has been pronounced the best in the garden. I never saw such a perfect plant as one that stands right in front of my garden sanctum, in the full sun on the ledge of a rockery. The plant quickly grew, after being turned out of a thumb pot, to the size of half-a-quarter loaf, as round as a ball, with little light green leaves, and with most beautifully formed flowers of the brightest scarlet, in such profusion as made it an astonishment for a time. Yes, for a time; there is not now (July 29) a single flower on the plant, and no promise of one either. I conclude, therefore, that *Advancer* will do for the London season, to blaze away from the beginning of June to the end of July, for the assistance of Parliament, who must want a little of the light of Nature on their work, even with such a trivial matter as the Reform Bill before them, and with the prorogation *Advancer* should disappear. While on this subject, allow me to remind all and sundry that once upon a time *Double Major* and *Minor Tropæolums* were not unknown to British gardens. Where are they now? It might be worth some one's while to make a stock of two or three good sorts, more especially the double orange colour *Minor*, and give them a fair trial out of doors next season.

Violas have been forced into fashion, and will soon be relegated to the herbaceous borders again. Some of my friends have been very much hurt that I did not join in writing up *Viola cornuta*; but I was content to say as much in its favour as it deserves—as, for example, that it is extremely pretty, quite hardy, and an agreeable tone of colour to soften down hard and glaring combinations. When our contemporaries were blazing away upon the subject, as if *Viola cornuta* were a new discovery, and capable of producing any colour in any quantity at the word of command, we had but a few plain observations to make, and there we quitted the subject. Time will justify our coldness, for in a year or two *Viola cornuta* will be scarcely heard of as a bedder, but many will owe to the extravagant laudation of the plant a knowledge of it, for as a hardy herbaceous plant they would never have accepted it on our quiet recommendation. There is a quite comic side to the *Viola* fervour, and it is that *V. calcarata* has been confounded with *cornuta*, and hence there are two *cornutas* in the market. *V. pedata* is possibly a better thing than either *cornuta* or *calcarata*; at all events, *Viola* hunters should look for it, and get a few tufts in growing order in some quiet place, ready to cut at when the rage for *pedata* as a bedder shall begin. An endeavour was made to puff *Viola lutea* into notoriety, but as a yellow bedder it would have to compete with two or three rather extravagantly showy subjects, and there does not appear to be any great chance for it. Yet all these *Violas* are lovely things; we have rejoiced in great tufts of them—"Velvet cushions" of mauvy blue, reddish slate, gray dashed with lavender, and bright gold-yellow—for at least twenty years past, and have praised them, perhaps, in public twenty times. But very few ever cared to hear of such things until they were proclaimed as bedders, and if by *that* means lovers of gardens are made lovers of beauty, let us be thankful. I am reminded of the case of the engine-drivers. The system of the companies has always been to bleed, purge, and de-marrow the men to the maximum for a minimum of pay, and so of course they were exposed to all weathers while performing their difficult duties. But one day there happened to fall a torrent of rain, and a driver, who thought himself the last on the road for the night, crouched down to avoid being blinded, for the rain smote him like a shower of arrows. Presently this train ran into another, a dozen people were killed, the company lost fifty thousand pounds by the business, and after that engine-drivers were provided with a sheet of iron to shelter them from the rain. Well, barring the loss of life, which is too dreadful a matter for the smallest word in levity, the fifty thousand pounds was well spent, though it was a long price to pay for the conviction that engine-drivers are human beings, and unfitted to face a blinding rain, and at the same time see far-off

signals, and keep their temper perfectly. Well, it has required a great row to convince a few people that *Viola cornuta*, *V. calcarata*, *V. pedata*, and *V. lutea*, are pretty hardy herbaceous plants. It was a row well worth making, I say, and I begin to be sorry I did not join in it. If a 40-horse power engine is needed to crack a nut, let us employ the 40-horse power, if the nut is worth cracking.

S. H.

BEDDING GERANIUMS.—No. XLI.

It is quite a proper thing to cast ourselves upon desert islands occasionally, in order to "realize" by fictitious means the relative values of the comforts in which our daily life is embedded. Who was it? Froude, surely, who said that if the Bible were blotted out from the literature of the world, nearly all the best books in existence must suffer obliteration with it, so much were they indebted to the Bible for facts, for ideas, for metaphors, for terms and phrases, for tone, purpose, spirit, and organization. I tried once to prove, for my own amusement solely, that Froude was quite wrong, and I took for my argument the text of Shakspeare; but I soon began to discover that, if not to the Bible directly and immediately, certainly to the systems and ideas that have grown out of it, Shakspeare was greatly indebted for a considerable portion of the spirit and life that pervade his works. What of the martial plays, in respect of the spirit of chivalry engendered by the Crusades,—those rash adventures that grew out of a zeal for the care of the Holy Places, and had for their sole object the vindication of the Biblical geography? What of the martial plays, in the wondrous part that the prerogatives of the Church assume in all of them, and to what else than to the Bible may we look as the fountain-head for their primary ideas? Even poor old Falstaff on his death-bed, "as cold as any stone," is "babbling o' green fields;" or, as Mr. Knight so ingeniously and happily suggested, is repeating in an hour of reflective penitence, in which memories of childhood are strong in the old sinner's heart, the 23rd Psalm: so if the Bible were blotted out from the world, that passage in Shakspeare—one of the grandest, too, in all the wide range of imaginative literature—must pass away, and be as if it had never been. We might go on in this way, but I shall pause, because I wish to return to the idea which started me on this discursion,—the idea that it is good sometimes to imagine ourselves cast away, solely that we may, in such a frame of mind as a sense of supposed extreme destitution might create, cast up accounts between ourselves and the world as to the relative values of things extremely precious to us. In a wreck of matter and a crush of worlds, when I saw the books being extinguished, I should endeavour to save the Bible and Shakspeare. To place these two books in so immediate juxtaposition will pain some good friends, but the lover of books, the real philosopher, the healthy humanitarian, will say that I am right. But I am quite ashamed to illustrate by this high argument the case that properly comes before me here,—such a case as this, in fact: if all the golden-leaved geraniums were threatened with extinction, which of them would you endeavour to save? I can answer the question for myself with the ease that a hawk drops from the empyrean to the clods like a stone, with the ease that always accompanies falling, but I fear with none of the dignity that has accompanied falls ere now, as when Lucifer fell, or as the waters of Niagara go on falling for ever, and are no whit degraded or lost. Yes, in plain prose, having got down to the clods, I can say plainly that *Golden Chain* is my first choice, and I say this after giving proper heed to every golden-leaved variety that ever has been known in this world, and with such heed as is needful in one who aspires to lead a company of believers in the right way. I am speaking solely for myself though; for *Golden Chain* would never give me any trouble, I could manage it as easily as Tom Thumb; but as there are people who profess it baffles them, we must consider the claims of *Cloth-of-Gold*, *Golden Fleece*, and some others that compete for notice when beds and bands of golden leaves are needed. The great vice of modern art, in all of its many departments, is *haste*. Men want effects produced in days or weeks that in gone time required months and years, and the periods of which have not been shortened by any legitimate mode, though they have been shortened by trickery. A painter now will finish a picture in the time that his master required for putting in the background, and they make wine old in a few days by means of a furnace, a thermometer, and a bottle containing in its texture a due proportion of baryta, which is the deadliest of all the poisons this bounteous earth produces. So, of course, only one per million of the folks who do bedding will give *Golden Chain* the time it requires; all the rest want to pave the ground with gold by an instantaneous process, and quick growth is of more consequence to every body except the one per million than fine quality. But to make short of this argument, I repeat that in the wreck of matter and the crush of worlds, I hope to save *Golden Chain*, should it happen at such a juncture that any geranium is worth a moment's thought. I can give it time, always did give it time. What if it requires three years to be effective, and seven years to

be grand? I can well afford that time, because in the interim, and while it is growing, there are a few other members of the vegetable kingdom capable of affording me amusement, and I can try my hand at getting up a variegated or double-flowered chickweed to drive dull care away.

For the quick race of mortals who want a crop in twenty-four hours after sowing the seed, one of the *Golden Fleece* school is the thing. And all three of that original group are good—that is to say, *Cloth-of-Gold* and *Gold Leaf*, in addition to the leader. And *Golden Fleece* is the leader, there is no denying that; and we need say no more about any of them, for they are just as well known as Tom Thumb or Aldgate Pump; and by the pretty star *epsilon* in Alphaus—a new thing to swear by—it is a wonder we have not yet heard of a geranium bearing the appropriate and elegant cognomen of Aldgate Pump!

"But to our tale," as one Robert once said, "ac market night." I heard of some good gold-leaved varietics, and went in quest of them, and they are now shining in baskets on the lawn, one basket—or rather one "*Leicester vase*" (fine vase too) being, in Miltonic phrase, "dight" with them. Now here in the batch is *Mrs Charles Barry* of the Dulwich Smiths, to which insufficient importance has been hitherto paid in this series. I can see in a garden that has no exact boundaries a clear furlong of it, as a front line to Hibberd's Pet, and the dark leaves and intense orange-scarlet flowers of the last show all the golden glory of *Mrs. Barry* to perfection. The new race of bronze zonals will light up this department in several ways, but they are as it were upon trial yet, and, for the rapid race and the steep descent that, like the water at Lodore, produces its effect at once, we must have sorts that are tried and cheap and quick growing, and certainly *Goldfinch*, in the classification of No. XL., would come into the Golden-leaved or Bronze Zonal class. Many of our favourites would go with equal ease into two classes, just as some dahlias do, and just as in every class that ever was devised, whether by Linnæus, Buffon, or Cuvier, the boundaries are such that some things can escape beyond them. Nature abhors a vacuum, said the old sages. Nature defies classification, we say; "but to our tale." *Goldfinch* has been extremely good here this season; but let no man talk of *Goldfinch* and *Luna* as if they ever could be competitors. But better than *Goldfinch* for golden leaves is one of J. J. Chater's, which we have here under the mysterious designation of 240. Wordsworth sang of "forty feeding like one," and I have seen ere now one feeding like forty. But here is 240 with a more golden leaf than *Goldfinch*, and a better scarlet flower, and a habit as compact as an exhibition cauliflower, but not a strong grower—moderate, in fact, that way. But why I should go from *Mrs. Barry* of F. and A. Smith to 240 of Chater begins to be a mystery, because beside it stands another labelled "J. J. Chater 142," which may be compared with *Mrs. Barry*, and will take a place beside it, and to some eyes be the better of the two. They are both bronze zonals, though the zone is passing into nubibus in both cases. In *Mrs. Barry* you can trace a zone; in 142 J. J. Chater you can see it, the colour being a light rust-red laid distinctly on a very strong yellow ground, very decisive, effective, and splendid. To say that both are good is to aver that I am not wasting time in writing this, and therefore superfluous; but I think 142 J. J. Chater will win in a hard competition, provided it will grow as compact as *Mrs. Barry*. Of the last our plants are in their third year, very compact big-headed bushes; but of the other yearlings, but big of their age, and brilliant in colouring. As to flowers, *Mrs. Barry* shows an abundance of neat trusses, in which the pips are as round as florins, and somewhat larger—very near indeed to the type that a florist can look at; the colour a clear light scarlet dashed with salmon or orange, or something less describable. In the other there is a starry, curly, small pip of a good strong scarlet. Flowers are no doubt useful sometimes, and in that case *Mrs. Barry* is the best, and the light scarlet over-spreading the yellow leaves is to me a pleasing harmony; but I can make allowances for people who don't seem to see it. *Annie Williams* and *Golden Nugget* I never did like, and never did praise; the first, to my eye, is waxy at the best, the other is indecisive. Yet these two have become favourites, and I may be in some degree fallible and in need of correction. *Crystal Palace Gem* of F. and A. Smith is first-rate, and you can see it in perfection now at the Crystal Palace: the colour is brilliant when the plant is in the full sun, and has a tide of sunny weather. *Jason*, *Lightning*, and *Waltham Gem* are good, but I see nothing in them to demand a chapter. *Neatness*, for plenty of flowers on a bronzy golden ground, is good; and *Canary Bird* is brilliant, and a grand bedder—in fact, one of the best bedders in the list. Of course, our readers are already impatient to see *Mrs. Pollock* in the competition here; but no, no, no, my dear friends, whose name is Legion. To look down on a bed or line of *Mrs. Pollock* is to look down on a pavement of vegetable jewelry—it is an event in one's life; but to go twenty yards away, and then look at the same bed or line of *Mrs. Pollock*, it is weak and indecisive, and *Golden Chain*, *Cloth-of-Gold*, or *Golden Fleece*, would beat it hollow.

S. H.

HORTICULTURE FOR THE CREDULOUS.

In the GARDENER'S MAGAZINE of June 22nd there is a paragraph headed "This is an age of wonders," wherein it is reported that a Mr. Firminger had discovered a process of growing peaches, plums, and cherries without stones, and at the same time describing the *modus operandi*. We agree with you "that such absurd inventions are calculated at the best only to provoke a smile at the expense of all who believe in them." We have not attempted to follow out the idea, so as to have the luxury of eating stoneless cherries, &c., but can imagine they would be very nice indeed. Some of your readers might be induced to try their hand at "the latest horticultural device," as the paragraph is headed in the daily newspapers, and perhaps the following may be of use to them. It may "provoke a smile," at all events, should no other good follow. In a book entitled "The COUNTRY FERME," published in the year 1586, the process is fully described. I give you a copy verbatim, and you will observe the process differs in no way with the modern invention. "If you hollow the branch of a Cherry Tree taking away the pith, and after set it againe it will bring fourth fruit without any stone: or else thus better: cut off a Young Cherry Tree within a foot of the earth cleaving it also even to the roote, take out the pith both of the one side and of the other, afterward ioyn them together againe, and tie them close with a straight band, and a Yeere after that this Cherrie Tree hath taken, graft therein a graft of a Cherry Tree which neuer bare fruit, and the fruit which cometh of such a graft will be without any stone. Otherwise, cut off from such stone fruit Tree as you desire, a graft which may be easily bended: sharpen it on the two ends, and graft it likewise on the two ends upon two partes of the Tree, make close the two grafted places with Mosse of fat ground, and tie them carefully with a band. The Yeere following if you see that the two ends of the graft have taken some force and strength from the stocke, putting forth sum buds, then cut the graft asunder in the midst, and take cleane from it the thickest sprig that it hath, and let the other grow, and it will beare in his due time fruit that hath no stone. The same will come to passe if you propagate the endes of the smallest boughes of the Yoong Chery Tree, Plum Tree, or other stone fruite Tree, and after that you have taken roote, if you cut off the thickest and fairest twig and let alone the leanest and slenderest. The reason and cause of this is, for that the Stone cannot grow, if the Tree lacke his pith, but in the tops and endes of little boughes there is no pith: therefore the fruit that cometh of them, whether they be planted or grafted after the Manner that hath bene said, will have no Stone, even no more than that which groweth of Trees whose pith is taken out."

The book from which these extracts are taken is entitled "Maison Rustique,"* or "The COUNTRY FERME." It contains amusing methods of "To fashion fruits after what shape that one will," "To graft a Vine upon a Vine," "Elegant Fruits," "One fruit having the taste of many fruits," "To Keepe Apples," and a multitude of other curiosities "too nnumerous to mention." I might give you extracts at some other time, should you think they would amuse any of your readers who may not have seen the book.

WILLIAM MEIN, *Kelso, N.B.*

Calendar.

WORK FOR WEEK COMMENCING AUGUST 3.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—Winter greens claim the first attention, and it is necessary to ensure at once a good supply, and a variety. By this time Scotch kale, Brussels sprouts, broccolis, savoys, &c., ought to be strong, and where they have been planted between rows of peas, to stand the winter, should now be looked over, and every other plant taken out, to make fresh rows, if they are at all crowded. Cabbages of most kinds may be sown in the second week of August; Shilling's Queen, Sprotborough, West Ham, and Red Dutch ought to have a place in every garden. Sow also Prickly spinach on slopes in rich soil, and plenty of hardy green Hammersmith, Silioian, and Black-seeded Cos lettuce. Sow cauliflower from the 7th to the 20th to keep over winter in frames. The summer-sown endive will now be strong enough to plant out on slopes or raised beds. Give plenty of water, alternating with liquid manure, to celery, and do not earth it up until it is well grown, the earthing being only to blanch it for use. Give plenty of water to broccoli and cauliflower beds, and top scarlet-runners. In good open situations, vegetable marrows for a late supply may still be planted. Use grass mowings to mulch the ground between crops that are likely to suffer from drought. Hoe between the rows of potatoes in dry weather, but do not draw the earth to the stems; the admission of air and sun-heat to the roots will hasten the ripening of the tubers; the foliage, where it remains green, should be injured as little as possible. Those that are casting their haulm may be taken up. Earth-up the earliest rows of celery; earth-up leeks; thin out the rows of parsley, so as to get rid of every plant not well curled. Remove decayed leaves from cucumbers and gourds, to prevent the growth of moulds and fungi about them in damp weather, and take cuttings, or sow seed, for cucumbers to fruit during winter.

Flower Garden

AUGUST WORK IN THE FLOWER GARDEN.—Propagate bedding plants for stock; of geraniums, ripe hard shoots make the best plants. Fuchsias come best from the points of young growing shoots. Strike verbenas and petunias from the points of young shoots. Calceolarias should be struck in chopped moss or peat. Herbaceous plants may also be struck in quantities to keep over winter in frames, such as pansies, dielytras, double walls, double Canterbury bells, double feverfew, and hollyhocks. Keep dahlias and hollyhocks well fastened, and put stakes to chrysanthemums before their heads get heavy, as a protection against storms. Pompones may still be struck for blooming in pots. Plant out pinks and carnations in nursery beds, in well-manured loam. Give plenty of water to chrysanthemums, with occasional doses of strong liquid manure. Look over your bins and heaps of compost with a view to replenish for autumn potting, as there will soon be a heavy demand for that purpose. Pansies may be sown, as may also most hardy annuals, to stand over winter for early blooming next spring; the latter should be sown thick, on poor, dry, hard ground, to induce a stubby and hard growth. Some seed should be saved for a second sowing in September, as, in the event of protracted warm weather, such as we had last year, some of the first sown may bloom this season. The sorts to sow now are calliopsis, Clarkia, Collinsia,

godetia, larkspur, lupinus, nomophila, nolana, French poppy, and dwarf schizanthus. There is still time to raise a stock of hardy perennials for next season, but not a day should be lost in getting in the seed. The most useful are antirrhinums, delphiniums, dianthus, geum, hollyhocks, Indian pink, lupinus, phlox, potentillas, silenes, sweet Williams, and wall-flowers. Those already up in seed-beds should be looked over and transplanted before they get drawn through being crowded. Plants left for any length of time to spindle are likely to perish in winter, and never can make such good specimens as those that have had plenty of room from the first.

ROSES.—Continue to bud roses and fruit trees, choosing damp dull weather—they take best just after heavy rain. In budding on the Manetti stock, enter the bud just above the collar, close to the ground, the proper mode of planting afterwards being to sink the base of the bud below the surface, so that the rose will root as well as the stock.

CHRYSANTHEMUMS.—Pompones cbrysanthemums may still be increased. Either the tops may be struck for pot blooming, or shoots of eight or ten inches in length may be layered into five-inch pots, and removed when moderately well established. Dwarf plants of the pompones and liliputian varieties are very useful for decorative purposes at the end of the season, and are adapted to purposes for which large bushy plants would not be so suitable. The large-flowered kinds do not bear to be stopped so late as the pompones.

AURICULAS should be turned out of their pots and repotted in rich turfy loam in a very sweet state. If overpotted they never do well. Keep rather close for a week after potting.

BEDDING PLANTS to be stuck in quantities for next year. The great secret of keeping verbanas and petunias through the winter is to have them struck early, and either planted into boxes or pans by the middle of September, so as to be established before winter. Strike bedding geraniums in the full sun in open borders. Short cuttings make the best plants. One eye with its accompanying leaf is sufficient of any scarce varieties, but mere eyes should not be put in the open border, but in pans under glass.

DAHLIAS are, in fine condition this season and much benefited by the recent rains. Thin 'the blooms, and tie out the growth regularly, or they will spread about and get snapped with the wind. Set traps for earwigs, and use the sulphur-duster if there is any appearance of mildew.

HOLLYHOCKS to be looked over, to see if the ties are too tight; sometimes they get crippled by the swelling of the stem causing the ties to pinch them where carelessly tied in the first instance. See that they are safely staked, so as to withstand storms.

HARDY SHRUBS and herbaceous plants may be propagated now in quantities from cuttings and divisions. Use a liberal admixture of sand, and choose a shady plot of ground for the purpose.

PANSIES.—Plant out from the cutting pans during showery weather, and shade till they make fresh roots. Make the last sowing of seeds the first or second week this month.

COLLINSIA VERNA.—Collinsia verna, introduced by Mr. W. Thompson, of Ipswich, is one of the most beautiful of spring flowers, and deserves to be extensively cultivated, not only in mixed borders and in pots for the conservatory, but is well adapted for ribbon and marginal lines in geometrio gardens, where its effect when planted *en masse* is equal to Lobelia Paxtoniana, to which, in its colours and habits of growth, it bears some resemblance. It is no longer needful to vindicate the distinctness of this species, that has been satisfactorily established; but it may be remarked that it is the only Collinsia that can be had in bloom in the month of April, a peculiarity which renders it invaluable for grouping with other spring flowers. The seed of this charming annual must be sown in the autumn; it will not vegetate if kept till spring. The best time is from the end of August to the end of September. Mr. Thompson recommends sowing in pans of light soil, and keeping those in a frame till the seedlings have developed their first pair of leaves, and then transplant them to the places where they are to bloom. It would be well also to keep a few pans of it in a pit, in case of severe weather killing those that were planted out.

HARDY HERBACEOUS PLANTS.—This being a good time to purchase and plant hardy herbaceous plants, we offer our [readers a list of the best 50 kinds known:—

- Anemone japonica, and varieties; flowering in autumn; 2½ feet.
- Aquilegia alpina and Californica; blue; summer; 1 foot.
- Delphinium, in variety; blue; summer; 3 feet.
- Helleborus niger; white; winter; 1 foot.
- Herbaceous Præonies; various; summer; 2 feet.
- Dielytra spectabilis; rose-pink; early summer; 2 feet.
- Baptisia australis; blue; summer; 3 feet.
- Ceronilla varia; pink; summer; 1 foot.
- Galega officinalis, and its fine white variety; blue; summer; 4 feet.
- Lathyrus grandiflorus; purple; summer; 4 feet.
- L. latifolius, and pure white variety; pink; summer; 4 feet.
- Orobos vernus, and varieties; purple; spring; 1 foot.
- Lupinus polyphyllus; blue; summer; 3 feet.
- Achillea Eupatorium; yellow; summer; 3 and 4 feet.
- Aster versicolor; white and pink; autumn; 1 foot.
- A. lævis; blue; autumn; 2 feet.
- A. elegans; white; autumn; 3 feet.
- Pyretbrum roseum, single and double, in variety; red; summer; 2 feet.
- Phlox, all the tall herbaceous varieties; summer; 3 and 4 feet.
- Campanula carpatica, white varieties; blue; summer; 1 foot.
- C. persicifolia, and varieties; blue; summer; 3 feet.
- C. rotundifolia; red; spring and early summer; 2 feet.
- Statice latifolia; blue; summer; 3 feet.
- Gentiana asclepiadea; blue; summer; 2 feet.
- Iris pallida; pale blue; early summer; 3 feet.
- I. Germanica, in great variety; blue; early summer; 2 feet.
- I. Florentina; white; early summer; 2 feet.
- I. variegata; striped; early summer; 2 feet.
- I. sub-bisflora; dark purple; summer; 2 feet.
- I. flabescens; light yellow; summer; 3 and 4 feet.
- I. amona; blue; early summer; 3 feet.
- Lilium exoelsum; cream; summer; 2 feet.
- L. longiflorum; white; summer; 2 feet.
- L. chalcedonicum; scarlet; summer; 3 feet.
- Tritoma glaucescens; red; autumn; 3 and 4 feet.
- Pitillaria meleagris, and its beautiful white variety, known to some as F. precox, spotted; spring; 2 feet.

* A French book translated into English by Richard Sorlet, Practitioner in Physique.

Narcissus poeticus; white; spring; 2 foot.
Iberis Gibraltarica, syn. *corraefolia*; white; spring and early summer; 1 foot.
I. saxatilis; white; spring and early summer; 1 foot.
Arabis albidia; white; spring and early summer; 1 foot.
Alyssum saxatile; yellow; spring and early summer; 1 foot.
Aubrietia purpurea; purple; spring and early summer; 1 foot.
Erigeron speciosus; blue; summer; 2 feet.
Centranthus ruber, and white variety; red; summer; 2 feet.
Potentilla, in fine variety; various; summer; 2 feet.
Pentstemon procerus; summer; 2 feet.
P. gentianoides or *Hartwegii*, all good varieties of; summer; 2 feet.
Tradescantia virginica; blue; early summer; 2 feet.
Lythrum roseum superbum; red; summer; 2 feet.
Eryngium amethystinum; blue; summer; 3 feet.
Dodecatheon Meadia, and varieties; light purple; summer; 1 foot.

Fruit Garden and Orchard House.

FRUIT GARDEN.—Throw nets over fruit bushes to keep off the birds, and give a little shade to keep a few bunches hanging for a late supply. Put wasp-traps about vines and peaches, or stick a few lumps of loaf-sugar among the branches, and as long as there is any sugar left they will not touch a single fruit. Nail in all good shoots on wall trees, that they may have the heat of the wall to ripen them. Encourage in every possible way the ripening of the wood of the season. If any trees have been allowed to get crowded, thin them a little now to admit the sunshine amongst the well-placed shoots and spurs. Windfalls to be sent into the house every morning for immediate use. Gather fruit in dry weather, and, as a rule, not till quite ripe. Plant strawberries.

Greenhouse and Conservatory.

GREENHOUSE.—Pelargoniums that have been trained out and pruned should be repotted as soon as they have broken regularly. Put them into the smallest pots into which their roots can be got, so as to allow of a series of shifts till they are once more in their blooming pots. Young plants and greenhouse shrubs should be well hardened now, before going to their quarters for the winter. Let canellias and azaleas have plenty of sun and little water. Summer-struck geraniums, achimenes, and fuchsias, may be got into bloom now, to keep up a display till Christmas. Shift all forward stock requiring to bloom early. Cinerarias should now be strong, and must have no check; see that they are kept clear of fly, for they are very subject to it. A cold pit is the best place for them. Sow now, for decorating the house in early spring, *Clarkia pulchella*, *Nemophila insignis*, *Erysimum Peroffskianum*, *Oenothera rosea*, *Collinsia bicolor*, *Veronica syriaca*, and Chinese primroses. Whatever needs potting pot at once. Late shifts result in deaths during winter. All plants winter best when their pots are full of roots.

AZALEAS must be trained into whatever shapes they are to have when in bloom, and the plants should be set out in a shady place to ripen their wood. Specimens to be exhibited next year must be trained out now.

CONSERVATORY to be kept gay by introducing a few specimen plants in good positions. Keep climbers regularly trimmed, and encourage the ripening of the wood of all hard-wooded plants, to ensure plenty of bloom next season.

CINERARIAS to be potted off from stock suckers and offsets; prick off seedlings; suckers not rooted to be put in as cuttings round the sides of pots, where they will make roots in a week. Beware of slugs and woodlice, which are tremendously fond of the young plants.

FUCHSIAS struck now will make nice plants to bloom early next season. To keep beds in bloom remove the berries, and shorten in any too vigorous growth; the side-buds will push and flower soon after.

PELARGONIUMS must be turned out of their pots, and the old compost shaken off for repotting, but never until they have broken well after having been cut down. Give plenty of drainage, and use as small pots as possible. Sow seeds gathered this season of all kinds of geraniums.

HELIOTROPES FOR WINTER FLOWERING.—Strike cuttings in August; the following spring select the strongest plants and pot into five-inch pots, and as they grow pinch back the shoots most determinedly, to lay the foundation for well-shaped plants. In June pot into nine-inch pots; place out of doors and frequently water overhead. By beginning of September they will be good specimens to take in for flowering all the winter and spring. Old plants, if cut back and watered with liquid manure, will produce several crops of flowers during the season.

HYDRANGEAS.—These are showy summer-flowering plants, and a few may be grown to assist in dressing vases, steps, or balconies. As they may, if kept rather dry, be put away under the greenhouse stage in winter, in spring they must be brought forward, and have good-sized pots, and plenty of liquid manure. The weak shoots must be thinned out, so that the principal shoots on which the next year's flower is to appear may be as strong as possible. The variegated variety is worth growing for its foliage; their flowers may be changed to blue by mixing iron filings and scales from the smith's forge in the soil. And very neat flowering specimens, only six inches high, may be had by taking off the points of the strongest shoots in August, inserting them in three-inch pots. Tie up their heavy leaves to a small stick; water freely, so as never to allow them to flag; place under bell-glasses till struck. The following season they will each produce a large truss of flower.

PELARGONIUMS FOR FLOWERING LATE.—Strike cuttings from the old flowering shoots as soon as the plants are out of flower; put them round the side of a pot; give no water for a few days, and place them on a shelf in the sun; for these cuttings are impatient of moisture until they have formed a callosity. If sufficiently rooted in September they may be potted singly into three-inch pots, kept in the warmest part of the house, and encouraged to grow. If nicely established in March they may be put into five-inch pots, and have their shoots pinched; they will then make nice little flowering plants. After flowering, place out of doors to harden, and in August cut well back, so as to ensure a dwarf compact specimen. As soon as their new growth begins, shade them out of their pots, trim their roots, and repot in pots the same size as those they came out of, or smaller, if the plants are weak; place in a shaded spot, and water overhead with a rose. In September remove to an airy shelf in the greenhouse for the winter, taking care to water cautiously, and not to wet the foliage, as water upon the leaves in winter causes them to spot and turn yellow. In February shift from five-inch to seven or eight inch pots, according to the strength of the plant, and place in the warmest and lightest situation at command;

pluch their shoots to the end of April, after which they must be allowed to run up for flowering. When approaching the flowering period use liquid manure.

STRIKING CUTTINGS.—Those who have the convenience of a hotbed may strike cuttings at various seasons, but those who have not such conveniences may strike most common greenhouse plants under bell-glasses placed upon the floor of the greenhouse at a distance from the light, during the months of July and August, and may raise seeds upon a shelf by placing a piece of window-glass over the mouth of the seed-pot, and shading with paper until the seedlings are fairly above ground, after which time both the paper and glass must be removed in the evenings, and be replaced during the hottest part of the day, until they have gained sufficient strength to dispense with them entirely. In July and August the shoots of most plants will be found in the most favourable state for cuttings—that is about half ripened—the air also sufficiently warm without artificial means to cause them to strike root, and by placing them under bell-glasses or hand-lights, at a distance from the glass, the light is so modified that they do not shrivel and dry up. Having filled the cutting-pots very firmly with sifted soil, in which an extra portion of silver-sand should be mixed, water thoroughly, and whilst the pots are draining prepare the cuttings, prick them round the sides of the pots with a small pointed stick, and close the soil about them by giving another slight watering, place upon the floor of the greenhouse with the bell-glasses over them, but remove the latter during mild nights, which will tend to prevent leaves rotting, and the cuttings damping off; but if the nights are windy, only remove the glasses for a short time. Water may not be required for several days, but this must be watched for, and when required, sufficient given to thoroughly moisten the soil. As they are found to have struck root they may be brought near the light, and the bell-glasses gradually withdrawn entirely from them, and those that are well struck previous to the end of September potted singly; but it will generally be best to leave those that are not struck by that time until the turn of the winter, otherwise they would not get sufficiently established before winter. Those who have no other convenience should provide a shelf very near the glass: the front of the house, if a lean-to, is best; but if a span-roofed house, of course either side will do equally well. This shelf should have a spline nailed on to both edges, so as to form a kind of trough; this should be filled with moss or sand, into which the small pots containing fresh potted seedlings or cuttings should be plunged; for if not plunged in some such manner there would be danger of their roots becoming too dry.

Stove and Orchid House.

STOVE.—All specimen plants in free growth must have attention now to secure a perfect ripening of the wood before the season closes. Let everything have now as much sun as can be borne without injury, which is best done by removing the shading from part of the house, and there placing whatever is likely to bear the exposure. Use water freely on the paths and beds to keep up a moist atmosphere, and give air at seasonable times liberally. Plants to be used for autumn and winter decoration ought now to be in a thriving condition; if any want a shift attend to it at once. Stop young plants of *Euphorbia*, *Aphelandra*, *Justicia*, *Poinsettia*, *Ixora*, *Æschynanthus*, &c. As the month progresses shut up earlier, and give less and less water to the roots of plants, and especially those which should be going to rest. If we have a period of dull chilly weather, use fire-heat, for a chill will do more harm now than in a month or two hence, when vegetation will be in a state of repose.

Forcing Pit.

VINES that have ripened their fruit to be cleaned. Where grapes are hanging give plenty of air, and keep the houses rather dry.

MELONS to be kept safe as to bottom-heat, or they will do no good. Shut up early, syringe on fine mornings, and give plenty of water, except when the fruit is ripening, and then keep them rather dry.

Correspondence.

MRS. PINCE'S BLACK MUSCAT GRAPE.

Seeing an inquiry in the GARDENER'S MAGAZINE of July 20th, respecting Mrs. Pince's Muscat, I beg to forward you a few remarks thereon. I was at Exeter some few days ago, and bought a fruiting cane of the new grape, and also saw the house of grapes, which I understood had been planted four years. From its appearance there can be no mistake regarding constitution; for the house, which is twenty-three feet long and thirteen wide, had over 230 bunches in it, which I consider more than one-half too many. The grape in all respects appears free in showing bunch and setting. The worthy proprietors have, I consider, not yet given the public a fair chance of seeing its merits, owing to heavy cropping. I think it a good grape in addition to our many late varieties; for Mr. Pince informed me that he cut bunches as late as the 4th of May from his house. The habit of the vine seems distinct, from its very wiry appearance of stem and leaf. I am going to plant the cane in our large lateinery, which no doubt you remember walking through when you were here in 1866. J. HANNAN.

The Gardens, Cyfarthfa Castle, Merthyr Tydfil, July 25th.

In reply to the inquiry of R. W. P., in page 318, respecting Mr. Pince's Black Muscat Grape, I have great pleasure in stating that I have seen it in its different stages of growth during the last three years. I have watched it with great interest, having had at the same time the care of three vineries, containing most of the newer varieties, in which I am greatly interested. Its habit is quite distinct; both wood and foliage look hard and firm, even when in a young state. In bunch it resembles the Muscat of Alexandria, when that variety is well done; in size and shape of berry, the Muscat of Hamburg, but the foot-stalks are shorter and more robust than in that variety. Its flavour is most agreeable—something like a mixture of Muscat and Frontignan. I believe its constitution to be such as to require for it but little treatment. The heavy crops of grapes ripened by the same vines in the Exeter Nursery for three successive seasons have proved it strong and prolific. But, added to the above, its chief recommendation is its valuable keeping qualities, which I believe far surpass "Lady Downe's." In flavour the latter has no chance against the former. In a garden where grapes are grown largely, I should recommend a house to be entirely devoted to Mrs. Pince's Muscat; where the object is to make

one house do duty over the largest possible time, I should say, to every four vines planted let there be one of this variety.

JAMES PEARCE.

The Gardens, Westlawn, Teignmouth, Devon.

I can venture to state that all who have had the chance of seeing Mrs. Pince's Black Muscat declare it a distinct first-class variety. It is one of those superb things which make a perfect photograph on the eye at first sight. Too much cannot be said for it. I first saw the vine in 1863, fruiting in a tub, smothered among hundreds of pot vines growing on for sale. In that unfavourable situation it looked at home, producing fine handsome bunches of jet-black oval berries. In the spring of 1864, I saw twenty-four anything but fine canes, planted in front of a small span-roofed house about 26ft. by 10ft. Feeling interested in the vine, I called from time to time to watch the character of it. It broke and bore fruit freely; the berries swelled off and stoned in perfection. Seeing the bulk of fruit they had to carry, I tried to persuade Mr. Pince to take one half off. Mr. Pince's answer was, "I intend to prove this vine thoroughly; they shall all bang. I will not send it out if it is not a beat on all its class." I expected to see the fruit no better colour than the old Warrington gooseberry, or that it would shank. Such was not the case; the bunches and berries were of the size and form of a well-filled bunch of Alexandrian Muscat. In 1865 these vines were more prolific, the bunches and berries much finer, keeping firm and free from rot up to April, 1866. The vines being then impatient of being longer retarded, what fruit was left was cut off and hung in a dry room, and in December, 1866, I had the pleasure of eating some of the fruit of 1865. In the year 1866 the vines had over 3 cwt. of fruit on them: the bunches were as large as in the previous year, but the berries were not quite so fine nor so well coloured; the want of colour was not owing to the heavy crop, but to improper treatment. As soon as the fruit showed colour, the moisture in the air and at the root was withheld, which was too soon for any of our solid-flesh grapes, and this is the most solid of any with which I am acquainted, and is a long time after showing colour before it is perfectly ripe. Not till the vines showed symptoms of distress did they get what they ought to have had long before, a good watering. With all this, the berries were a good passable colour: the true colour is equal to Trentham Black. After Mr. Pince had sent samples of it to different parts of the country, a few bunches were left in March, 1867, to hang as long as they would. Unfortunately they had drawn the attention of Mr. Rat, who could not resist the temptation to rob the vine of its finest black berries, there being but one bunch not touched; it was protected, and it hung to the end of April. The vines requiring much moisture, it was cut in as good condition as it was in November. This year the vines are again covered with long handsome bunches, and are in perfect health. The constitution of the vine has been severely tested by over-cropping and less than ordinary treatment. It has thoroughly proved itself to be the most prolific and the most free from disease of any vine which we have in cultivation; and as regards quality, it is quite a Black Muscat in flavour as well as in shape of bunch and berry. I am sure no connoisseur or cultivator of the vine who once sees Mrs. Pince's Black Muscat will fail to make speed to plant it.—WILLIAM CRAGG, *Gardener to J. C. Bowring, Esq., Larkbeare, Exeter, July 25th, 1867.*

I believe this grape to be quite distinct in habit and fruit, and I think there cannot be two opinions about its good constitution and prolific qualities, as the vines can be seen growing there, both with and without fire-heat, bearing enormous crops. Nothing can be more vigorous or healthy: splendid bunches were cut as late as May 4th this year. It proves to be a first-class grape, surpassed by none. I sincerely trust it will meet with the hearty reception it deserves from all grape-growers.—SAMUEL SALWAY, *Gardener to W. F. Splatt, Esq., Flete, Ivy Bridge, South Devon.*

CYPERUS ALTERNIFOLIUS.—The variegated form of this plant is frequently described as one of the most refined and beautiful subjects in cultivation. I well remember your description of a remarkable specimen that was shown by Mr. Tanton, at one of the Guildhall exhibitions, and I have observed lately that you have found fault with some amateurs for showing it with green leaves. What is very simple and easy to you is sometimes very hard to us, and this is a case in point. I know something of plant-growing, but this beauty beats me. I find it difficult to keep, much less to grow, and as to showing it wholly variegated, that appears to be out of the question, not only for me but for all other cultivators in the midland counties. Do pray afford us some practical help, or get your able correspondent, Mr. Tanton, who appears to be the first man in the country with this plant, to tell us the story of his management. I am sure such information will be a boon to hundreds of the readers of the GARDENER'S MAGAZINE.

R. W. STEELE.

WELCOME TO THE ROSES.

Roses, roses, beautiful flowers!
Pearly and pale and pink-lipped roses,
In ye, the light of the laughing hours,
The smile of the summer sun reposes.
Children of distant climes are ye,
Flushing the vales with your purple bloom,
Living your life on the breast of May,
And steeping her breath in your soft perfume.
Near ye the nightingale tenderly sings,
Loving and lone, in the pale moonlight;
His gushes of song, like falling springs,
Bathing in music the lids of night.
And when your reign in the east is o'er,
He looks to the sea and he prunes his wings,
And seeks once more, on our northern shore,
The rose that he loves in a later spring.
For blossom and bud you then are ours,
And ours the voice of the nightingale,
As it floats along on the breath of flowers,
Dewy and soft, through the star-lit vale.
Beautiful strangers! your home is far;
Yet welcome, and three times welcome here,
To us, who, beneath the ice-king's star,
Sit songless and flowerless half the year.

Chambers's Journal.

Replies to Queries.

Suffolk.—Your rose-trees are badly affected with red fungus, and there are evidences also of the ravages of thrip. The best mode of procedure, to prevent further mischief and to save the autumn bloom, will be to occasionally sprinkle the foliage on the under side at daybreak with fresh lime, slaked and powdered, and at the same time give abundance of manure-water to the roots. Probably three dressings above and below, at intervals of three days each, will make your roses right for the season.

W. C.—It is too late now to pinch trees of any kind; the reason there are so many failures is that people who do not understand it begin the work just when those who do understand it are leaving off.

Food Value of the Potato.—S. B.—You may admire Cobbett, and yet not be deluded by his notions about potatoes. The following extract from Dr. E. Smith's "Practical Dietary" will afford all the information you want, and be useful, perhaps, to others besides:—"That kind should be preferred which becomes mealy on boiling, and which, when well cooked, can be thoroughly crushed with the finger. The potato which is known as 'waxy,' and those which remain somewhat hard when boiled, do not digest so readily as the mealy kind; but for that very reason they are said to be more satisfying. . . . It is not material in reference to nourishment whether the potato be boiled or roasted, since in both methods it should be well cooked. In point of economy and convenience, however, it has been found better to boil than to roast them; for whilst the loss in boiling upon 1lb. of potatoes scarcely exceeds half an ounce, that in the most careful roasting is 2oz. to 3oz. It is also more economical to cook them in their skins, and to peel them immediately before they are eaten; but this is not very convenient in many families, and the colour of the potato is not quite so agreeable as that of those which have been boiled after peeling. When they are peeled before boiling, and particularly when they are small, and the operation is performed carelessly, from one-third to one-fourth of the whole weight of the potato is lost, and if there be no pig to eat the peelings the whole is wasted; whilst the weight of the peel which is removed after boiling would not amount to more than 1oz. in the pound. When potatoes have been roasted, the loss in weight from the skin and drying is more than one-fourth of the weight before cooking. An average sample of potato, after it has been peeled contains 11 per cent. of carbon and 0.35 per cent. of nitrogen; and hence in each pound there are 770 grains of carbon and 24 grains of nitrogen, and it is greatly inferior to bread. The economy of its use depends upon its cost; so that in times when potatoes are sold at 3d. and 1d. per pound they are very dear food as compared with household flour, whilst they are a very cheap food when produced by the labourer at the cost of the 'seed' and the rent of land. Thus, at 3d. per pound, only 1,024 grains of carbon and 32 grains of nitrogen will be obtained for 1d.; when the cost is 1d. per pound the quantities will be reduced to 770 grains and 24 grains. When the labourer, however, can obtain 50 bushels of potatoes from a quarter of an acre of land, at a cost of about 30s. for seed and rent, he will have more than 7lb. of potatoes for 1d., and the quantity of carbon and nitrogen thus obtained for that sum would be 5,770 grains and 200 grains. If, however, he were to sell a large part of his crop at the market price, he would procure with the money thus obtained far more nutriment in the form of flour than would have been derived from that portion of his potatoes. The weight of potatoes which alone would supply the daily nutriment required by a man would be about 6lb. in reference to the carbon, and 8lb. in reference to the nitrogen; but when a labourer in the west of Ireland lives upon this he is allowed 10½lb. daily, besides a large supply of buttermilk, and as both of these kinds of food are cheap in that locality, the proceeding is even then an economical one."

Rats.—B. B.—There are several ways of killing rats. The best way of all is to procure some Carbonate of Baryta, which is a cheap article. Pound it, and mix it with the meat of a good bloater, or with flour and water and minced fat. The mixing should be done without touching the stuff with the hands, and if the Baryta is in the proportion of a tenth part of the whole it will be effectual. It is not wise to place poisoned food in their runs, for they are suspicious of such marked consideration. It is better to place it in a vessel, as if intended to be preserved with care, with a lid which the rats can remove to get at it. Having to make an effort to obtain it, they will eat it greedily; but if they discover by their keen scent that it has been handled, and see it placed rather in their way than out of it, they will turn up their noses in disgust, and entertain the utmost disrespect for you. If arsenic is preferred, the best mode of procedure is to mix it with barley-meal in a clean basin, with a little milk or water, using a wooden or iron spoon. Or broil a bloater on the gridiron, and while cooking powder the arsenic upon it. We prefer the Baryta, because it can be compounded in a shed; but to arsenicate a bloater one must go to the kitchen, and we prefer that a deadly poison should never be placed in the neighbourhood of food intended for human beings.

Gourds.—S. S. writes to say that he is anxious to preserve pure seed of certain races of gourds, but he finds in his plantation several hybrids, the result of crossing last year, and which he regards as rogues. If he destroys these rogues, he spoils his plantation, for it is too late now to plant again; if he leaves them alone, they will possibly spoil for seeding purposes those varieties which are at present true. S. S. may easily escape this difficulty. He must remove all male flower-buds before they open; the females may be left to swell their fruit, as they will be fertilized by the males of the typical kinds. The fruits on the rogue plants may be used young as marrows, or when ripe for any of the purposes to which ripe gourds are put, but the seeds taken from them must be destroyed. To sum up the advice in few words, nip the male buds from the rogues, and eat all the fruits the rogues produce.

Grass Leguns.—G. Harris.—Yours is the common, too common case. You go on for years taking grass off the lawn, and you put nothing on. Of course the soil gets exhausted, and will only produce daisies. Guano or rotten dung, or any good artificial manure, will change the scene.

F. S. Barlings.—Your seedling potunia is a large semi-double flower, defective in form, and rough, but of good substance, and likely to be a superb bedder. The colour is brilliant violet-crimson shading to violet centro, exceedingly rich and massive.

R. Taxton.—Your seedlings are of quite average merit; throw them away. Do not take seed from Christine at all unless you practise cross-breeding in a systematic and scientific manner.

FORCED FUN.—When a man is as "cool as a cucumber," may he be said to be in a cucumber-frame of mind?

The Gardener's Magazine.

SATURDAY, AUGUST 10, 1867.

Mrs. PINCE'S BLACK MUSCAT GRAPE has been the subject of anxious inquiry amongst grape-growers, and the result is that the whole of its history is now before the public. That it should excite curiosity somewhat beyond the average of similar subjects, may be attributed to two circumstances—first, the reports of its peculiar excellence as a table grape and its long-keeping properties; and, secondly, the somewhat out-of-the-way locale of the parent vine, which has prevented many of the best judges of grapes from seeing it. However, it has been seen by many of the best grape-growers in the country, and in these pages their testimony has been given in favour of its general adoption where a long-keeping grape of the finest quality is in any respect a desideratum.

The history of this grape is interesting. The late Mrs. Pince—who, like her much-respected husband, Mr. R. T. Pince, of the Exeter Nurseries, was an enthusiast in horticulture, and well versed in many of its mysteries—was one day eating a bunch of grapes, and observed that one of the berries contained a peculiarly large round stone. She desired it might be sown. This was done, the vine grew, and in the year 1862 first produced fruit. Mrs. Pince was not then living to witness the evidence of her good judgment and perception in regard to the sowing of the selected seed; but the seedling plant was observed to possess some peculiar properties, and it was named, in remembrance of her, "Mrs. Pince's Muscat," and has now become such a memorial of her virtues as those who hold her name in affectionate remembrance can best desire. On several occasions this variety has come before us for critical examination, and we have had in every case to report in its favour. Yet, in truth, it is but lately that the whole character of the variety has been manifested; its immense fruitfulness and its good keeping could be ascertained only by the test of time, so that, from promising at first to be an admirable grape, it has proved at last to be one of the very best at the command of the cultivator. In the "Garden Oracle" of 1864 we reported on it as "the best grape of the year," having become acquainted with it in the autumn of 1863. In the GARDENER'S MAGAZINE we have several times directed attention to it, and have made public our impressions, derived from seeing the original vine at home, surrounded by abundance of its progeny, the parent commencing its new growth while fruit of the previous year still remained upon the rods.

In growth this variety is peculiar. The young wood is of a purplish hue; the leaves are small, nearly triangular, deeply and elegantly lobed, and of a bluish tinge of green. The bunches are large, long, tapering, well shouldered; the berries oval, as large as those of the Muscat of Alexandria, purplish black with a thin bloom. They are borne on short, rigid, green stalks, with thick warted re-

ceptacles, a character which in some part accounts for the length of time the bunches will keep good if left hanging on the vine. The skin is tough, but scarcely thick; and this, again, is in favour of late keeping, for no tender-skinned grape can be kept long after ripening. The flesh is firm, sweet, exceedingly rich, and of a decided Muscat flavour, changing, however, to a Frontignan flavour after the bunches have been long kept.

One of the special advantages resulting from the distribution of this variety is, that in places where there is much demand for grapes in spring it will lessen the labours and anxieties of the cultivator, and in some cases render early forcing unnecessary. It is in its prime from the end of January to the end of April; keeping improves it, and the second-class varieties in cultivation which are valued chiefly for their keeping will have to yield up their places to it, for it will assuredly supersede them. Mr. Meredith, of Garston, who knows as well as most people the commercial value of a first-class spring grape, to be obtained in abundance without forcing, has lately built a house expressly for this variety, and in almost every good garden in the country young canes will be planted during the present autumn.

Now that Mrs. Pince's Muscat is in course of distribution we must cease to regard it as in course of probation.

Its character is established, its fame secured, and we confess a feeling of peculiar satisfaction in having been enabled to assist in giving publicity to the merits of so valuable an acquisition. With these remarks we present our readers with a figure of a portion of a bunch which measured 11 inches in length by 10 inches across the shoulders. The artist has depicted the shape and colour of the berries admirably, but he has not represented the foot-stalks and receptacles sufficiently stout to be quite truthful.

Mrs. PINCE'S BLACK MUSCAT (Portion of Bunch).

FUNGI ABOUND EVERYWHERE at this time of year, and many kinds that would furnish palatable and wholesome dishes are rejected through the common but not unreasonable fear of poison. Mr. Hardwicke, of Piccadilly, has just published two large coloured sheets of figures of fungi, one sheet comprising the edible, the other the poisonous kinds. They are from drawings by Mr. W. G. Smith, who has most happily hit the characters, so that they may be quickly identified when found. A volume of letterpress accompanies the plates. We earnestly recommend the introduction of the book and plates into every school-room in the country, and into every reading room, garden library, and wherever else a question may be likely to arise respecting the wholesomeness of a fungus.

EUROPEAN PLANTS FOR AUSTRALIA.—Dr. F. Mueller, of the Melbourne Botanic Gardens, writes as follows to Dr. Berthold Seemann:—"I should like to introduce, not only to the Lagoon in our hotanic gardens and its banks, but also to suitable localities in our mountain glens, lakes, &c., some of the very ornamental European swamp and other plants of the kind mentioned below, or of others of similar habits. May I, therefore, ask your kind assistance in begging you to collect for me, during your excursions, seeds (or living plants, if readily available), and forward them by one of the fast-sailing vessels to my address. In exchange, I shall be most happy to send to you seeds of our beautiful Australian plants. To indicate the class of plants specially referred to, I would name the following, and must leave it to you to add such others as you may have an opportunity to procure: *Lychnis Flos-cuculi*, *Lysimachia thyrsoflora*, *L. vulgaris*, *Hottonia palustris*, *Circea Lutetiana*, *Paris quadrifolia*, *Glaux maritima*, *Butomus umbellatus*, *Sagittaria sagittifolia*, *Menyanthes trifoliata*, *Parassia palustris*, *Stratiotes aloides*, *Pinguicula vulgaris*, &c. A collection of the various species of *Salix* and *Rubus* would also be most welcome."

THE SEASON.—After a second deluge, that has laid flat the ripening corn, we have accidentally taken up from a mass of papers a cutting from a popular magazine, which was sent to us some months ago for insertion in these columns. We produce it *now*, in illustration of the doctrine to which men of scientific experience cling tenaciously, that it is not in the power of man to predict the weather more than a few days, or at the utmost a week, in advance:—"The *People's Magazine* predicts that the coming summer will be one of the hottest on record, the deduction being made from the following axioms established by Dr. Kirwan: First, that when there has been no storm before or after the spring equinox, the ensuing summer is generally dry, at least five times out of six. Secondly, that when a storm happens from any easterly point, either on the 19th, 20th, or 21st of March (the equinox), the succeeding summer is generally dry four times in five. Thirdly, that when a storm arises on the 25th, 26th, or 27th of March, and *not before*, in any point, the succeeding summer is generally dry four times in five. Fourthly, that if there be a storm from S.W. or W.S.W. on the 19th, 20th, or 22nd of March, the succeeding summer is generally wet five times in six," &c., &c., &c. Any of our readers curious in this matter may be interested to know that in the *Floral World* of November, 1866 (p. 322), we pointed to the great probability of 1867 proving a bad season, but there was no admixture of prediction with the statement, and we begin to be firmly persuaded that predictions, come from whom they may, if they attempt to overpass a period of five to seven days in the future, deserve to be treated with contempt.

NIEREMBERGIA RIVULARIS, beautiful alike for its fresh green leaves and pure white salver-shaped flowers, promises to prove quite hardy in this country. For this we were not quite prepared, yet it is consistent with the geography of the plant. As it is easily propagated, we hope those who have strong plants will at once plant them out, to remain for the winter, and at the same time take a few cuttings to make plants to keep through winter under glass. It will be one of the neatest and most pleasing of all known bedding plants, and, if quite hardy, one of the most valuable.

SALE AT BRISTOL.—A sale of a portion of the stock, together with a series of plant-houses, of the Durdham Down Nurseries, Bristol, is announced for the 19th of August and five following days, in consequence of the approaching expiration of Messrs. Garraway and Co.'s lease. The catalogue comprises selections of azaleas, camellias, amaryllis, orange and lemon trees, ferns, palms, and other first-class subjects.

IN THE REGULATIONS FOR THE EXHIBITION to be held at Manchester on the 27th and four following days, it is announced that "Sale prices may be affixed to the objects exhibited." This is a good regulation, and might be much more generally adopted than it is. It appears that some intending exhibitors are in doubt as to when the plants may be removed. They will find a regulation to this effect, "The objects exhibited may be removed after six o'clock on the evening of Saturday, the 31st of August." Entries close on the 17th.

THE extent of land under potato cultivation in France is 2,040,364 acres; in Austria it is 1,308,148 acres; in Ireland, 1,050,412 acres; in Bavaria, 649,735 acres; in Great Britain, 498,843 acres; in Belgium, 369,850 acres; in Sweden, 334,000 acres; in Holland, 265,987 acres; in Wurtemberg, 167,948 acres; and in Denmark proper, 69,176 acres.

A GREAT variety of plants foreign to France have sprung up under the walls and around the buildings in the Park, the seeds of which have been conveyed to Paris in packages from various countries for the Exhibition. Especially around the house of "Gustavus Wasa" several plants may be seen which are peculiar to the country of that monarch.

THE *City Press* of last week gave an interesting account of a flower show held in the girls' parochial schoolroom of St. Dunstan's Fleet Street, when Messrs. Broome and Dale, of the Temple Gardens, acted as judges, and the rector distributed the prizes. Amongst the objects exhibited special mention is made of an india-rubber tree, also of rhubarb, potatoes, and hop plants, besides the usual geraniums, fuchsias, and musk plants, all of which were grown by poor people, mostly children, in the narrow ways that lie behind Fleet Street and the Strand.

THE SEMPERVIVUMS AND SEDUMS: A WORD ON THEIR CULTIVATION, WITH A SELECTION OF THE BEST OF THE HARDY SORTS.

Of all families of hardy plants, this is one of the most interesting and the most neglected. In fact, although some of them are among the most interesting and singular of all known plants, there are many horticulturists who do not know a sole species, except it happen to be the house-leek. People have rockworks, it is true, and a poor hand they make of them as a rule, generally substituting free-growing weedy plants instead of such things as the best of these Sempervivums, which are of all others most suitable for the choice rockwork. But this is not the end of their advantages. They are amongst the hardiest of all plants, standing any weather, though generally grown in pots, and living even in smoky London, where many things the people generally think much more hardy and vigorous perish in no time. There is not a window-sill in London to which the light of the sun can occasionally penetrate on which they may not be grown, either in pots or boxes, while in all open gardens they merely require to be kept free from weeds and "left to nature." To the cottage or garden of the poorest they will lend an interest; any of our largest gardens would be improved by their presence, suitably arranged and associated. Generally it is rare to see them in cultivation, but lately a splendid species, *S. californica*, has come into use as a first-class hardy edging plant, and a few of our nurserymen happily possess stocks, so that no reader need be in want of some to make a beginning with; and doubtless some day a large proportion of our nurserymen will find it to their interest to cultivate this neat and interesting class. We will now give a selection, premising it with the remark that our selection is not, as is too commonly the case, one from books, but from actual experience with a great number of the species. We will not confine ourselves to the best kinds solely, but enume-

rate all, or nearly all, in cultivation, indicating the best kinds with an asterisk. This is desirable for two reasons: nearly all the species are worth growing, all are neat and pretty, and if we omitted half those in cultivation our work might not meet the wants of those with wider range of selection than ourselves.

Almost the same remarks apply exactly to the very neat and interesting *Sedum* family, and therefore we will not repeat anything in the same strain, but furnish lists of the cultivated species of both families, beginning with the *Sedum*, as it has the first place in the orthodox botanical order of things. For all rockwork the family is indispensable, while occasionally they furnish a first-class plant for the fronts of borders, as in the case of *Elegans*, *Kamtschatium*, and *Pulehellum*.

THE SEDUMS.

A list of the species in cultivation in British gardens, with the best kinds indicated by an asterisk (*):—

<i>Sedum acre</i>	<i>Sedum hispidum</i>
* " variegatum; golden tinge on shoots	ibericum
aizoides	involutatum
Aizoon	Jacquinii
albescens	* Kamtschatium
album	libanoticum
" turgidum	littoreum
altaicum	Lydium?
" sibiricum	* monregalense
altissimum	maximum
anglicum	* multiceps
* Anacampseros	neglectum
arborescens	ochroleucum
" monstrosum	orientale
asiaticum	pallens
aureum	* pellidum; very good
Brauni	pulechrum
* brevifolium; rather tender, but very pretty	* pulehellum; very pretty
Beyrichianum	American species
cæruleum	populifolium
* corsicum	" msjus
* cruentum	reflexum
cruciatum	" collinum
cyaneum	rupestre
* dasyphyllum	* sempervivoides
dentatum	sexangulare
denticulatum	sexfidum
* elegans	Sieboldii
elongatum	" variegatum
* Ewersii	spectabile
Fabaria	speciosum
fabariform of C. Lemaire; the fine, new, and strong herbaceous species	* spurium; very pretty
Forsterianum	stellatum; distinct colours
* farinosum; tender, but very pretty	Stephani
* glaucum	Telephium
" monstrosum	telephoides
grandifolium	teretifolium
* hispanicum	ternatum
	triangulare
	villosum
	virens
	* Verlotii
	Wallichianum

THE SEMPERVIVUMS.

A list, with the best kinds marked (*):—

<i>Sempervivum acuminatum</i>	* <i>Sempervivum hirtum</i>
anomalum	juratum
* arachnoideum	Mettenianum
* " majus	molle
arenarium	montanum
* assimile	Neirichii
* Brauni; light green	* piliferum
canescens	* Pittoni
Catyledon	Pomelli
ciliatum	Requieni
* californicum	ruthenicum
dioicum; large and good	* soboliferum
Funkii	* stenopetalum
glaucum	tabulare
* globiferum; very large and fine	tectorum var. rusticum
grandiflorum	urbicum
Heuffellii	velutinum
	villosum

It should be observed that the above are authentic lists of the kinds really identified, and that there is no family in which mistakes of nomenclature are so likely to be made. We finish with a few observations on kinds of *Sempervivum* not in cultivation in England, or but very rare. They are as follows, and should be laid hold of by our readers whenever they have a chance, as they are very good:—

<i>Sempervivum Doellianum</i> , very neat	<i>Sempervivum violaceum</i> , distinct
barbatulum, slightly tomentose, and very pretty	assimile, very good
pilosella, ciliated edge; very good	calcareum, fine
tectorum var. rusticum, very good	fibriatum, very good
Connollii, very large and good	albicum, neat
Verlotii, good and distinct	soboliferum, if true, is one of the best, with large rosettes, surrounded by young ones of a pink tinge
Schleana, very good and distinct	piliferum of Jordan, very good
Boutignianii, also very good, distinct, and large	With these <i>Umbilicus chrysanthus</i> should be associated.
affine, A 1	

BEDDING GERANIUMS.—No. XLII.

The creamy leaved varieties, the *VARIEGATED par excellence* of No. XL. (class 4), are very curiously planted in the circle that opens close beside my garden sanctum. They form a circle cut through at two opposite sides, with a circular bed of blue lobelia within, the variegates forming two semicircles beyond, and they have for relief front lines of the variegated *Dactylis*! It is about the coolest bit of colouring possible—a centre bed all blue, and two outer semicircles all white; but it is pleasant, for there are green trees all round and about, and the only remark proper to the case would be, "What a queer taste!" Now there is reason in roasting of eggs, the adage says, though I never could see it, for I never did roast eggs. I once tried to bake some on the sly, in "the days when hope and life were young," and they burst and spilt their contents among the hot embers,—and contributed a most elegant varnish, or a sort of gutta-percha coating to some potatoes that were put into the same embers to keep them company. Like many other strange things, it admits of explanation; but to explain it from beginning to end will require about half a dozen folio volumes, which I have not time to write just now. But I'll tell you the use of the scheme. The *Dactylis* affords a great semicircle on each side, of a constant tone of gray or whitish vegetation, and with this constant tone in a great mass all the characters of the variegates behind it are quickly discernible; the *Dactylis* becomes in fact a point of reference for the eye, and it helps to show instantaneously the intensity of white in any particular geranium, or the depth of cream, the tendency of cream to pass to pale sulphur, and all the intermediate stages. It is a sort of standard of comparison, and its dwarf spreading habit eminently fits it to serve as a means of constant comparison; and this is the pith of the history that may be written, if I live long enough—say about the year 1900 perhaps, or perhaps not. In the circle there are 72 varieties, all of the creamy or white edged kinds, and amongst them the one to be taken, on the wreck and crush hypothesis, according to my taste and judgment of such matters, is *Daybreak*. I have carefully compared this with *Flower of Spring* and *Silver Chain*; the first of these two inclines more to cream colour, the second is nearest like *Daybreak* of any in the series, and all three are good. I find in *Daybreak* these special qualities,—free growth, leaf not more wrinkled than other good varieties, and frequently convex, which is better than concave; the margin is irregular, but it always shows a large breadth of creamy white. If a choice must be made between *Flower of Spring* and *Silver Chain*, then undoubtedly *Silver Chain* is the best, and only a shadow in point of merit below *Daybreak*. If I had to choose a second to *Daybreak* for my own keeping, it would be *Rosette*, for this would give me another shade of leaf, and an altogether different flower. The growth of *Rosette* is compact and dwarf, yet not wanting in vigour; the leaf is much wrinkled, but generally inclines to convexity, the margin is broad clear whitish cream, or creamy white, with the shadow of a pink zone; the flowers are a delicate shade of pink. A fine plant of *Rosette* in a pot is one of the most chaste and refined objects possible in all the range of bedding geraniums; and when bedded there is not so strong a reason for removing the flowers as in the case of variegates with scarlet flowers. I shall now go round and pick out a few good ones. *Oriana* grows very compact—I find a plant as round as a ball, though in a quite shady part of the ring; the colour approximates very nearly to sulphur; it is at all events as deep as the richest Devonshire cream, and the spare, starchy, yellowish green disk shades into the margin, producing an intermediate tint: its distinctness is one point in its favour, and its peculiar hue adapts it well for showing up a line of blue, or indeed for relief to any positive colour. *Silver Queen* is intermediate in tint between *Oriana* and *Silver Chain*; there is much sulphur in the disk, which we may call yellowish green; the margin is creamy rather than white; the leaf is peculiarly round, not much wrinkled, and generally inclined to a shield-like convexity; a robust grower, but compact, well-behaved, and effective. *Lady Palmerston* I like, though it is of the *Bijou* type, and the leaves are rather cupped, which is a fault; but the rosy pink flowers are plentifully produced, and a bed of it is chaste, pleasing, lively, and it makes an attractive pot-plant. It is, however, far from first-rate. *Flower of the Day* is far in arrear of many newer kinds in respect of quality, but it is a good serviceable thing, and keeps its place in all public gardens, by its ability to withstand dust and its free habit of growth. It must be remembered, however, that in great places, where they have a stock of an old thing like this, they go on using it for the simple reason that they have a stock, though if they had, or could quickly obtain, a sufficiency of some other kind, better in many respects, they would give up the old one. Another reason for the favour shown to some old things in great places is that they are used to them, and do not readily take to better things. Nevertheless I put *Flower of the Day* in the rank of reliable serviceable varieties, and we must not yet kick it out of the select list. *St. Clair* is good,

the flowers especially, but the clean creamy leaves are the proper criterion of its merit. The *Variiegated Stellas* number some half-dozen now, and all very much alike, and all beautiful, clean, slow-growers, with objectionable cup-shaped leaves. I was about to forget *Silver Nosegay*, *Snowflake*, and *Venus*, all good. I think we may very well stop at this point. We have enough, certainly, for suiting every taste and every soil and climate where variegates can be grown at all. Amongst the new ones, we have one of very fine quality, and a decided advance on *Daybreak*. It is labelled "40 J. J. Chater." A small plant turned out of a thumb in May is now a foot across, branching from the bottom, the leaves showing a large proportion of white, and the plant conspicuous in the circle of 72 by its distinct bright character and contour. From the same source we have a remarkable variety, labelled "147 J. J. C." It is hatefully coarse, with huge *Bijou*-like leaves, most of which are cupped, the disk dark green, the margin white as snow.

And this coarse brute of Chater's brings us to consider the bad ones, and I place *Bijou* front in this series; for, though beautiful, and when old exceedingly free to flower, it will not, as a variegate, bear comparison with the good ones named above. My old plants of *Bijou* have made shoots a foot long this season. As plants they are grand, but for any of the purposes to which variegates are usually put, this is about the last I should choose. I would never have it while *Daybreak* or *Flower of Spring* were to be had. *Bijou* will be swept out of the garden this season, with a hundred or two others that are condemned. In the list of the condemned I find *Argus*, which is not clean; *Perfection*, not enough variegated, and too rank a grower, but, like *Bijou*, fine for scarlet flowers; *Culford Beauty*, curly and coarse; *Hendersonii*, curly, coarse, and colourless; *Queen of Queens*, not so good as when it first came out—time has made a weed of it; *Meteor*, good, but no special character; *Attraction*, marred by the inconspicuous, almost dirty zone when it grows freely; *Countess of Warwick*, same objection as the last—remember, both are good in pots, and to breed from; *Mrs. Hoyle*, a bad form of *Perfection*; *Mountain of Light*, a poor grower; *Mountain of Snow*, not showy enough for the present day; *Brilliant*, nothing for leaves, and in other respects beaten by *Brilliantissima*, which can be bought now for a shilling.

There is a peculiarity in the growth of geraniums that very few are acquainted with, and yet it may be explained in a word. All the variegated kinds, including such as we are now especially dealing with, and all others, whether popularly known as bicolors or tricolors, are of compound constitution: in every leaf there are two or three classes of cells, which extend and multiply in different ratios. When we see young plants in pots, we see perhaps flat leaves, and we say, "This is perfection." We plant them out, they acquire increased vigour, some part of the leaf grows faster than another part, and the leaf ceases to be flat. There is no exception to this rule; it applies to *Mrs. Pollock*, *Luna*, *Flower of the Day*, *United Italy*; to one and all alike free growth always adds to their imperfections, though it may, and usually does, increase their attractiveness. The variegates proper, such as come into class 4 of our system, are the most subject to become cupped, or convex, or wrinkled, because between the green disk and the white margin there is greater antagonism, or rather greater difference in degrees of vigour, than between any two classes of cells in the leaves of other varieties.

Another matter of great importance is this, that free growth always increases the darkness of the zones. A rich soil will add to the aggregate of black in *Mrs. Pollock*, and give greater effect to the red and yellow thereby. A rich soil will fully develop the dark but generally obscure zone in *Countess of Warwick* or *Attraction*, and spoil them both. A rich heavy soil will so increase the black and diminish the red in *United Italy* as to make it almost worthless; to show its proper colours at their best, *United Italy* should be in a bed of light, fresh, rather poor soil, raised above the level; but to make the best of *Mrs. Pollock* a generous soil should be used, to give full effect to the colours. Geraniums of every kind are more healthy, and flower more abundantly, if the beds are raised a foot or eighteen inches above the general level of the ground—this is especially the case with such as are of delicate constitution. I can grow *United Italy* so that it shall glitter with shades of creamy white and carmine, or show so much of black as to be unsightly. When in heavy and well manured ground the black comes out prominently, and the leaves become deeply cupped; hence it frequently happens that people condemn it as worthless, after having themselves taken pains to spoil it. S. H.

When is a forcing-frame like a pigtail that always gets in your way?—When it's a-queene-umbering you. N.B. This joke, raised from a frame, is naturally a little forced.—*Fun.*

Messrs. Veitch and Sons, the well-known Chelsea nurserymen, have introduced a new pea this season. In recognition of the eminent services of our well-beloved Cole and Co., and to preserve a name the world would not willingly let die, they have named their new variety *The Brompton Boilers*.

CYPERUS ALTERNIFOLIUS VARIEGATA.

CYPERUS ALTERNIFOLIUS has been known in English gardens since 1781, when it was first introduced from Madagascar, where, in common with the Lattice-leaf plant (*Ouvirandria*) and other valued inhabitants of our stoves, it is an abundant river weed. It takes its specific name, "alternifolius," from the alternate arrangement of its leaves; and its generic name "Cyperus" carries us at once into the great family of sedges, to which it properly belongs in the natural arrangement of plants. The sedges (*Cyperaceæ*) may be collectively considered as plants removed one degree in the order of structure from the grasses (*Graminaceæ*). Many of them may be readily mistaken for grasses by unbotanical wayfarers when traversing an English waste, the British species being usually much more grass-like than those of exotic origin. The peculiar characteristics of the Cyperus family are the following: the leaves are usually hard and rigid, sometimes sharp as a razor at the edges; the stems are usually solid, not, as in grasses, hollow and jointed; the flowers of our British species of *Carex* are distinctly unisexual, the males presenting themselves in cone-like catkins, the females in elegant feathery plumes. There are other points of distinction, less obvious in their nature, and respecting which I must refer the reader to some good botanical work; I have simply pointed out a few in order to correct, without giving offence, those cultivators who persist in regarding the plant now under consideration as one of the grasses. In the order to which this plant belongs, it has for congeners our British species of *Cyperus*, *Scirpus*, *Eriophorum* (the well-known "cotton grass"), and the exotic *Papyrus* of the Nile, the very elegant *Isolepis gracilis*, which is almost a true *Scirpus*, and several other plants of less repute. The variegated form of this *Cyperus* is of quite recent introduction, and it is of this form alone that I intend now to speak.

There are few plants of modern introduction which really deserve more attention than this. Its graceful beauty justly gives it claim to be considered one of the most conspicuous of fine-foliage plants, and yet we seldom see it either grown as a fine specimen or luxuriating with that degree of vigour which is essential to the development of its peculiarly high and characteristic elegance. An unhappy stunted form of growth, with almost every alternate leaf diverging from the true character, is the general aspect of plants one is accustomed to see, both at exhibitions and in private gardens; and in the hands of manipulators, too, whose other performances would lead us to expect better results.

There are two reasons to account for this failure: in the one case a better knowledge is required of the peculiar requirements and habits of this charming exotic sedge; in the other the variety is at fault. As in the case of many other forms of beautiful plants, there have been distributed of this two distinct varieties. One is the true plant as imported, and increased by division; the other, speaking of the aggregate as one, consists of seedlings which have been raised from the true variety. Young plants, propagated from the former by division, always retain their character, which is typical, of tall, slender, vittately-marked footstalks, surmounted with a whorl of leaves about half-an-inch broad and upwards of a foot in length, and bearing the same character as the stems. The regular alternate lines of pure white and green, together with the pendulous habit of the whorl of leaves, gives a well-handled plant a most refined and imposing aspect. Seedlings seldom, if ever, acquire this beauty: their habit is dwarfed, the leaves generally push up green, are shorter, with the markings inconstant and indefinite, and withal are plants of no beauty in comparison with the true variety. I find propagation by division of the root can be done at any season of the year, and if your plants are rooted by the month of March they will make nice plants, bearing from four to six good leaves, by the following autumn. In potting, the several materials should be well prepared and incorporated, namely, fibrous peat, leaf-mould one year old, very old brick mortar, wood charcoal reduced to powder, potsherds broken very fine, and very sharp silver sand, in about equal proportions. The pot must be well drained, and a layer of cut sphagnum laid upon the drainage, upon which place the ball of the plant, carefully packing the material round, and pressing the mass gently to render all firm. The plant should then be put into a cool division of the stove, where plenty of direct light is secured. This is necessary to prevent a too great accumulation of chlorophyl—that is to say, a tendency to too great an accumulation of green in the leaves. This plant is semi-aquatic, and, with free and unimpeded drainage, delights in moisture. I find large pans filled with pebbles and water to the rim, in which the plant should be placed, most beneficial. The moisture imbibed by those roots ramifying amongst the drainage, and the slow and constant evaporation of moisture immediately around and beneath the leaves, has the effect of increasing the vigour, and thus enhancing the beauty of the plant. It likewise acts as an antidote to all kinds of insects. A moist genial atmosphere must be secured by the free use of the syringe throughout the summer, and until the month of October, when atmospheric moisture must be partially

withheld, and the plant taken off the moist pebbly pan, and kept drier throughout the winter or resting season. It is when in this condition that the plant really should be propagated. The ripe side eyes, if judiciously taken off, will readily root. From the specimen in my possession, and which has received high honours from the Royal Horticultural Society and other metropolitan exhibitions, I have this season secured upwards of two hundred fine young plants, all possessing those charming attributes of character of which my specimen is characteristic.—RANSLEY TANTON, F.R.H.S., Nurseryman, Epsom, Surrey.

CONSTRUCTING A VINERY.—No. I.

What are the principal points to be attended to in the construction of a vinery? is a question so often asked, that I have found it necessary to go fully into the details of the subject in order to furnish a useful reply. With a view of making the subject of general interest, I shall treat all the principal points under separate headings, giving such information as my experience has afforded me.

POSITION.

As a general rule a southern aspect is considered by many as the best under any circumstances; but in this I must beg to differ. A south aspect is eminently adapted for those who do not force grapes, or indeed for those who do not start their vines until February. But for those who begin forcing in November, a south aspect is not so well adapted as one a point more eastward; for this reason, the house that stands a point to eastward secures earlier in the day the sun's influence when our dull dark November climate admits of its penetrating the dense fogs and mists which then usually abound. By securing the sun's influence upon the house as soon as it is sufficiently risen in the horizon to distribute its welcome rays, the cultivator is enabled to give air early in the day, to dispel the stagnant atmosphere enclosed in the house, which every one knows is essential to the health of the vines. Moreover, when a house is so placed that the sun's rays fall upon it soon after it is risen, that house has the benefit of a greater amount of light than one on which it does not act for an hour later in the day; for the sun not only carries in its rays a certain degree of warmth even in November, but it also furnishes a great amount of light—and as most members of the vegetable world succeed best in proportion to the amount of light supplied them, the vine being no exception, we can readily understand the importance of so placing an early vinery that it may have the full benefit of all that it is possible to secure at a time of year when our climate only gives us a limited supply of daylight. I might properly add a note on the importance of securing the sun's heat early in the day, and how it gives strength and substance to the vines; and how much more agreeable is the heat so obtained for all vegetation than any that can be supplied artificially. But these are points that will appear clear to every unbiased mind without any arguments of mine.

I have briefly stated above that for later forced grapes a south aspect is admirably adapted, and so it is for those not forced at all; but it is a folly to suppose that even late grapes cannot be grown on eastern aspects. All they require is a very light constructed house, and a very well regulated system of air giving; that is to say, to open early in the morning and shut up early in the afternoon: as, for instance, houses facing south-east will bear shutting up at 3 p.m., while on a south aspect 4.30 or 5 p.m. will be soon enough.

THE WALLS.

The foundations should be concreted on a firm bottom, and the walls not less than nine inches thick; fourteen inches would be better for the back wall of a large house, or range of houses. For late houses, I like the front wall on arches, that the roots may work both inside and out; but for early work the border should be inside the house, and the roots confined to its dimensions. Brick piers for the front are objectionable, unless they are placed at every three feet, and an extra strong wall-plate to carry the roof. Where there are sliding lights on the roof, the back wall should be carried eighteen inches above the roof, as a sort of parapet. This affords great shelter from the north winds when air is given by the top lights; it also breaks off the rain, and is a protection against a sudden storm.

DRAINAGE.

To secure a proper drainage for the border and floor of the house is also most important, as well as to take away the water from the roof. But the roof-water should, in the first instance, be conducted into a tank or cistern inside the house, to be used in watering the borders, &c., an overflow being provided from the tank to the drain, to take away all superfluous water, for which there should be a gradual fall to the outlet, that there be no impediment to obstruct the water in its course away, as stagnant water is fatal to the roots of vines.

FLOOR OF THE HOUSE.

If the house is intended for very early work, the roots, as above stated, must be all inside, and the border for the most part covered with a wood trellis, that when the operator is giving the necessary attention to his vines there may be no treading upon the border, which tends to render the soil impervious to air and water. These trellises may be removed after the grapes are thinned, and the vines require less attention, except a line of them through the centre, or where there is most traffic, as the border will be all the better for not being covered up longer than necessary. If the roots are partly inside and partly outside, then a wood trellis to walk upon as a pathway will suffice, taking care to fork up lightly any footsteps that may from time to time be made upon that portion of the border not covered. A wood trellis is to be preferred to either a stone or tile paving, as it admits of a more even distribution of air and water to the roots.

MODE OF HEATING.

Unquestionably, for large houses, hot water is the best, but for a small single house a flue is not to be despised. For a house thirty feet by twelve a flue will answer every purpose, and I should advise that a flue be used, unless there are other houses in close connexion with it. In this last case a saddle boiler, with a sufficient quantity of four-inch piping, should be supplied. The quantity of piping required to heat a house of a certain size depends entirely upon the time it is intended to commence forcing the vines. For a house thirty feet long and twelve feet wide, four four-inch pipes will be necessary if the vines are started in November; but if forcing is not commenced until the 1st of March, then two four-inch pipes will do. The same remarks will apply to a flue—that is to say, the earlier the forcing, the greater length of flue will be required.

INSIDE versus OUTSIDE BORDERS.

In the foregoing remarks I have given the preference to inside borders for very early forcing houses, not because I prefer them to properly heated and constructed outside borders, but I have recommended them in this case because they are more simple in making, and of less expense, and when properly managed they answer every purpose. A good chambered and properly heated outside border, with every requisite appliance for protecting the border from wet and cold weather, is in some instances better than an inside one; but borders of this sort add considerably to the expense, and, from what I can gather from the communications of those asking for advice, they are not likely to be adopted by them.

In my next communication I propose to deal with the making of the border; meanwhile, those who are thinking of making new vine-borders should secure at once the principal ingredients, particularly a sufficient quantity of the top spit of a good mellow fibrous loam from a pasture field or a similar spot. J. C. CLARKE.

THE CULTURE OF VERBENAS IN POTS.

It is greatly to be regretted that many of the most useful local horticultural exhibitions have ceased to exist, and with no probability, at least for the present, of ever being restored. What caused them to decline? Perhaps this is a question not so difficult to solve. If we take a retrospective view of their rise and fall, we shall find that their decline may be traced in a degree to the desire, on the part of some of the exhibitors who were considered the lions of the show, to endeavour to monopolize the prizes, by the reduction of the number of subjects for competition, and thus turn the whole affair into a commercial transaction, somewhat similar to the system followed at our large horticultural exhibitions. Thus the purpose for which local shows are established, that of giving encouragement to many exhibitors, and the greatest variety of productions, is departed from. There can be no question but that the originators of local shows, from the manner in which the list of awards were framed, aimed generally to improve the cultivation of fruits and flowers in their own locality, and to inspire a spirit of laudable ambition to excel in the growth of their several products among gardeners. All gardens are not alike in size and accommodation for aiding the gardener in achieving great results in connexion with the several species of the vegetable kingdom, especially those which require a high state of cultivation. A gardener may be conversant with all the requirements for producing superior cultivation, and yet not have the means to aid his skill. It is then he resorts to the cultivation of plants which are best adapted to the circumstances that govern his operations; and local shows have been great helps in developing these resources, by offering prizes for subjects that are considered unworthy of a place in the schedules of our leading horticultural exhibitions. Amongst many good subjects that schedules of great shows do not recognise, and which ought, therefore, to have liberal encouragement at local exhibitions, the verbenas as a pot plant deserves a leading place.

Much has been said from time to time in the columns of this paper respecting the individual merits of the several varieties of verbenas. Having within the last week had an opportunity of viewing several of the best varieties in flower at Mr. H. Cannell's, The Fuchsia Nursery, Woolwich, and elsewhere, of which I shall speak at a future period, it has occurred to me that I might employ my pen usefully for a short while in an attempt to simplify the practice of producing specimen verbenas in pots. But I must endorse the opinion of the Editor in the issue of August the 3rd, respecting the qualities of the new crimson verbenas, the *King of Bedders*, having witnessed a bed of it in full bloom in the garden of the successful raiser, Mr. Todman, gardener to — Hudson, Esq., Clapham

Common. As a hedder, it was flowering in profusion, producing a most brilliant effect. In my opinion, it is far in advance of Admiral Dundas in colour and size of bloom, besides partaking of a more vigorous habit. It must become a general favourite as it becomes better known. But to return to their value as pot plants for ornamenting the greenhouse or conservatory when in flower. For that purpose they are far more beautiful subjects when trained with taste. Of course there are many varieties which are not suitable for pot culture, especially those which partake of the habit of Purple King. In selecting, make choice of those which produce large heads of bloom. Distinctness of colour is another thing to be observed, so as to make them when in bloom not only attractive, but interesting. The present is the season for choosing your sorts, while they are in flower, and in doing so you must question the grower as to their habits, if you do not see sufficient to justify you in your choice; for sometimes valuable varieties are overlooked for the want of inquiry as to their fitness for the required purposes. For selecting plants, the present time is about the best during the year, because most of the plants now growing are from late struck cuttings. Such being the case, they are generally clean and healthy, and more so if the pots have been plunged in any cool materials under glass, as decayed tan or leaves, for example. Besides, you have the advantage of seeing their flowers, they being more decided in colour now than earlier or later in the season.

Having procured your plants, reduce their shoots, if long, to two or three eyes—the object being to keep them bushy while young. As soon as the breaks are visible, pot them into five-inch pots. Use plenty of drainage. The soil should have mixed with it a fourth of silver sand. After you have shifted them, put them into a cool frame, and keep shaded from the burning rays of the midday sun. As soon as you consider them sufficiently rooted in the new soil, uncover them during the day, and continue to stop the shoots as they may require. The object in putting them under glass is, that they may be the more easily protected from heavy rains. Keep the wood as short-jointed as possible at this stage of their growth, by having the plants always near the glass, and freely ventilated. Do not think of further shifting them till the following February. The most suitable place for them during the winter is the top shelf of a greenhouse, or a pit that is heated by hot water or otherwise. The most destructive enemy they have to contend against during the winter months is damp, which creates mildew, and the green-fly, which, if allowed to gain the ascendancy, will soon destroy the vital energies of the plant. To guard against the former, give plenty of air on all favourable occasions; and as a preventive to the ravages of the mildew, always dust the plant with powdered sulphur at the first appearance of the disease, and so continue to repeat the dusting till there is no further signs of its presence. Fumigation with tobacco is the only remedy for the destruction of the green-fly; and by way of economy, if the other plants in the house do not require to be fumigated, then put the verbenas into a box or hand-light for the purpose, and when you consider the fly on them destroyed, give the plants a gentle syringing, after which replace them in their former position. If you are anxious to have them in full bloom by the latter end of May or beginning of June, you must, if the plants are thrifty, shift them in the month of February into their flowering pots; and that you may get them well established in the same, let their pots be plunged into a mild bottom heat. They will, from this time till their flower-buds appear, require to be grown in a warm moist atmosphere, and their shoots stopped often, if they show a disposition to become long-jointed.

As regards the style of training, that is a matter of taste. I have had them trained to a balloon trellis with good effect, and equally so on a flat surface, with a slight rise in the centre, similar to the mode adopted by the growers of zonal geraniums. Thus treated, I have seen some very large plants grown in nine-inch pots, and literally covered with bloom. In their final potting they must have plenty of drainage; any kind of soil that is sweet, and of a light loamy texture, well incorporated with decayed manure or leaf-mould, with some silver sand, will suit them. I have been favoured by request with the following list of varieties, as being the best adapted for pot culture, by Mr. H. Cannell, who grows all that is worthy of being cultivated for sale:—

Name.	Colour.	Remarks.
Harry Law	Shaded purple	Very large flower.
Queen of England	Salmon, and fiery scarlet centre...	Large, smooth, and flat.
Fanny Martin	Clear rose	Pleasing flower.
Antonia	Rich claret-crimson	Fine truss.
Leah	Pink, white eye	Good shape.
Triomphe de Massiffs	Grand blue... ..	Desirable flower.
Madame H. Stenger	Bright scarlet striped with white	Distinct and delicate.
Earl of Radnor	Rosy scarlet	Free bloomer.
Un pare	Cerise-purple	Largest flower in cultivation.
Mrs. Turner	Pale flesh	Splendid variety.
Mauve Queen	Mauve	Very fine.
Annie (Cooling's)	Striped	Finest striped ever produced.

JOHN F. McELROY.

OBSERVATIONS ON THE PORTRAITS OF KENT AND BROWN, AT THE SPECIAL EXHIBITION OF NATIONAL PORTRAITS.

I wish to offer a few remarks respecting the portraits of two landscape gardeners now on view at the Special Exhibition of National Pictures, South Kensington, namely, William Kent and Launcelot Brown, better known as "Capability Brown."

WILLIAM KENT was born in Yorkshire, 1685. He was apprenticed to a coach-painter, but, aspiring to a higher path, he repaired to London, and there, aided by some gentlemen of his own county, proceeded with Mr. Talwin to Rome, where he studied under the Chevalier Luti, and gained the second prize in the second class in the Academy. His first resources failing, he found a patron in Sir W. Wentworth, and finally in Lord Burlington. With this nobleman he returned to England, and resided at his house as a painter. Kent was painter enough to appreciate the charms of landscape; he was bold and conceited enough to dare and to dictate, and moreover he had genius sufficient to strike out a great system from the twilight of imperfect essays. Mahomet imagined an elysium, but Kent created many. It is said that Kent frequently declared that he caught his taste in gardening from the perusal of Spenser's picturesque descriptions; but we are indebted to Mr. Walpole, his contemporary, for the outlines of his style of design. The great principles on which he worked were perspective and light and shade. Groups of trees broke too uniform or too extensive a lawn; evergreens and woods were opposed to the glare of the champagne; and where the view was less fortunate, or so much exposed as to be seen

at once, he blotted out some parts by thick shades to create variety, or to make the richest scene more enchanting by reserving it to a farther advance of the spectator. Where objects were wanting he introduced temples, &c.; but he especially excelled in the management of water: the gentle stream was taught to wind about at its pleasure, and where interrupted by different levels its course appeared to be concealed by thickets, properly interspersed, and it glittered again at a distance, where it might be supposed naturally to arrive; its sides were smoothed, but preserved their meanderings. His ruling principle was that Nature abhors a straight line. The grounds in which the above principles were most strikingly carried into effect were those of Stowe, near Buckingham, then the residence of Lord Cobham. His lordship was an amateur designer, but employed Bridgman to assist him.

LAUNCELOT BROWN was born in Northumberland. His first employment was as kitchen gardener to a gentleman near Woodstock. He afterwards moved to Stowe, and confined his exertions to that department. Lord Cobham recommended him to the Duke of Grafton, who appointed him head-gardener at Wakefield Lodge, Northamptonshire, where his judicious formation of a lake first brought him into notice as a designer. Lord Cobham still continued his patron. Among other places, he was employed at Blenheim, where, by his easy completion in a week of one of the finest artificial lakes in the world, and other improvements, he rose to the height of popularity. He never went out of England, neither did he ever contract to execute his plans. He employed assistants to draw his designs. "Improvement," says Loudon, "was the passion of the day, and there was scarcely a country gentleman who did not consult him." The leading outlines of his system were easily copied, and imitators innumerable arose to supply the demand for designs. The spade and axe were at work in every estate, and so rapidly did the face of the country alter, that Sir W. Chambers declared that, if the mania were not checked, in a few years more three trees would not be found in a straight line from the Land's End to the Tweed. Whenever consulted upon the alterations to be made in the grounds, he invariably observed that there were "great capabilities about it;" hence arose the nickname of "Capability Brown." Brown possessed taste to comprehend that which is pleasing, and genius sufficient to obtain in some of his designs very good effect. His management of the water at Blenheim can never be excelled. In this material of landscape he was most excellent, but in the management of the ground he was less happy. He seldom varied in his plan. His declivities were all softened into gentle slopes. Plantations belted the estate, while clumps and single trees were sprinkled over its area. These were planted without any consideration or object which taste pointed out as desirable. That he was not always successful is most certain; it must be allowed that he undertook more than he could perform, and the art became most monotonous; and, as Mr. Loudon says, the professor required no further examination of the ground than to take the levels for forming a piece of water, which water uniformly assumed one shape and character, and differed no more in different situations than did the belt and the clump.

Brown was evidently aimed at, under the name of Layout, in a novel entitled *Village Memoirs*, published in 1775, in which he is represented as a general undertaker of gardens, who introduces the same objects at the same distances in all. The excellent translation of *Girardin de la Composites des Paysages* points out distinctly the correct and true taste in designing. The *Picturesque Tours* of Mr. Gilpin, the *Essays on the Picturesque*, by Mr. Price, and *The Landscape*, by Mr. Payne Knight, completed the expulsion of the Brunonian system of garden design, and prepared the way for the better fashions that now prevail.

WILLIAM GILES.

SUGGESTIONS FOR THE IMPROVEMENT OF THE VERBENA.

Looking at the numerous and remarkably diversified varieties of Verbena which now adorn our plant-houses and flower-gardens, or at the still more numerous and formidable array of names which fill large sections of nursery sale catalogues, none who have not previously ascertained the fact could possibly conceive that scarce thirty years have passed since the original representatives of this universally admired race of showiest summer flowers first received anything like general cultivation in British gardens; yet such is unquestionably the case. In 1826 Mr. Pousette collected seeds of several verbenas in the neighbourhood of Buenos Ayres, which he transmitted to John Hawkins, Esq., of Bignor Park, Petworth, Sussex, where, under the management of his gardener, Mr. John Perry, the first flowered in May, 1827, and was figured from a plant grown by Mr. Harrison, gardener to the Earl of Egremont, in Sweet's "Botanical Register" of the following year, under the name of *Verbena Melindres*, given to it by Lindley, in ignorance that it had been previously called *V. chamadrifolia* in Persoon's "Synopsis" by no less an authority than Jussieu, a circumstance which led to a little confusion, in consequence of its being known under both these names among cultivators. That such a brilliant-coloured and neat-habited plant should have been hailed as a most important acquisition was nothing more than what might have been expected; and accordingly it became the popular flower of the day, and was eulogised as follows in Maund's *Botanic Garden* for February, 1831: "Its flowers are intensely brilliant, without glossiness, and yet it has a dazzling effect on the sight, not unlike the lustre of polished metal. The eye cannot rest upon it without evident uneasiness. If any artist or artisan, in the pride of his heart, assume to himself excess of merit for the tints he has discovered, let him look on this plant, and subdue the intemperate heat of his imagination." Such was the admiration bestowed upon *V. Melindres* that verbenas in general were popular, and not only were old obsolete species resuscitated, but new ones were eagerly sought for, more especially in South America, which had become noted as the land of verbenas. Of the former, *V. bonariensis*, introduced from Buenos Ayres so early as 1732, and *V. Aubletia*, from North America in 1774, again became common inhabitants of our gardens; and of the latter, *V. venosa*, brought home in 1830, *V. Tweediana*, as well as *V. Sabini*, in 1834, *V. incisa*, in 1836, and *V. teurcroides*, in 1837, were received by cultivators into particular favour. Of these, *V. Tweediana* and *V. incisa* are so closely allied to *V. Melindres*, that notwithstanding their having been separated from it, and named by such an eminent authority as Hooker, the propriety of considering them as distinct species has been questioned. In the *Botanical Magazine* for December, 1836, *V. Tweediana* is described as having much affinity with the last-named species, but differing from it in being of a much taller and more upright habit of growth, "clothed with soft downy hairs, of a much more delicate texture, especially in the

leaves, which are considerably larger, more acuminate and serrated, more cuneate at the base, and decidedly petioled. The flowers are larger and more inclining to rose colour ('rich rosy crimson'), in greater number, and the racemes more capitate." In the same magazine for January, 1838, *V. incisa* is described as "another South American verbenas of the *Melindres* group; it is extremely handsome; the blossoms are of a deep red rose colour, with a yellow eye, and become paler in age; it differs from *V. Tweediana* in the broad and depressed (not spiked) corymbs; and in the broader leaves, which are more deeply lobed, and cut in a pinnatifid manner." In Paxton's *Magazine of Botany* for December, 1838, appeared a well-executed figure, along with the following description, of *V. teurcroides*:—"The plant is erect, and grows about 2 feet high; its flower spike is generally more than 6 inches long; the flowers are of a delicate pinkish white, gradually deepening into rich rosy pink as they begin to decay; and they are delightfully fragrant. It first flowered in the Glasnevin Botanic Garden in August, 1838;" and Mr. T. Handasyde, of Muselburgh, who purchased the whole stock, first sent it out in April, 1839.

From these four reputed species, *V. Melindres*, *V. Tweediana*, *V. incisa*, and *V. teurcroides*, have sprung almost all the most popular verbenas now in cultivation; and while it may be conceded that little room for further improving these seems now to exist, in the lines of advance which cultivators have hitherto chosen, yet there are others which would afford ample scope for the exercise of their skill; among which we would specially particularize those of habit of growth and of fragrance.

In regard to habit, it is a remarkable fact that among all the now popular verbenas none possess the dwarf spreading growth of the original *V. Melindres*, the departure from which first arose by crossing it and the *V. Tweediana*, and became consummated when that so-called "improved strain" became in its turn further incorporated with the still much more vigorous growing *V. teurcroides*. To overcome this strong up-growing tendency in modern varieties, recourse is had to the tedious and (to render it effectual) continuous operation of pegging down, which, even when best performed, never gives that close surfacing of foliage which the *V. Melindres* spreads around of its own accord. As flower and not leaf improvement has hitherto been the principal end aimed at by growers, it follows that some of the most perfect blossoming kinds are, in both the earlier and latter parts of the season, little different in appearance from common nettles; and while this is the case in the warmer and drier districts of the country, it is more noticeable in the upland and moister parts. Hence some eminent horticulturists who are so situated never attempt growing the coarser leaved kinds, and even still depend largely on the *V. Melindres* and other low-growing sorts for their principal floral display. Dwarf compact growth is not, however, the only desirable habit for verbenas; but a much taller habit than has yet been attained is also desirable, provided it can be acquired in combination with good foliage and stout graceful outline. The six feet high *V. bonariensis* possesses these desirable characteristics, and is only deficient in size of flower. This defect might, however, be overcome by hybridizing it with some of the large-flowered kinds, which might produce a new race of verbenas far more elegant and effective than anything yet seen.

Fragrance is a property which verbenas improve have almost entirely ignored, and among all the varieties now in cultivation it is doubtful if any will stand comparison in this respect with the old "delightfully fragrant" *V. teurcroides*, from which most of the whites and other strong-growing large-foliaged kinds are descended. And what a success would be obtained were a hybrid connexion produced between that universal favourite, the lemon-scented *V. triphylla*, and the showy-flowered kinds! In attempting the attainment of this highly-desirable result, we would caution hybridizers not to be deterred because botanists have separated this old favorite from the verbenas, and restored to it its original name of *Aloysia citriodora*, for by art and skill they may be enabled to overleap this fanciful barrier, as easily as they have already done seemingly more difficult obstacles, in amalgamating other separated genera.

Variating the foliage and doubling the flowers of verbenas are other lines of improvement in which little or almost nothing has yet been done. By prosecuting the former the most objectionable features in the plants may not only be overcome, but rendered really ornamental; and by the latter, longer endurance in the flowers, that invariable accompaniment of doubling, will at least be obtained.—*The Farmer.*

THE BOG PIMPERNEL.—On occasion of visiting the College Botanic Gardens lately (says a writer in the *Irish Farmers' Gazette*), and passing through the cool conservatory, in which there are many interesting plants, our attention was at once arrested and fixed on two—a palm and a Dracena—not exactly on their own account, but by reason of the beauty with which our little *Anagallis tenella* clothed the surface and sides of the pots in which they grew. The pots were large—one, indeed, of the largest size—and the surface of the soil in both was cushioned with, and their sides beautifully draped and almost hidden by its very long thread-like stems that dropped perpendicularly from the rims. Each of these stems was prettily strung with its double row of round bead-like leaflets, and glistening for nearly half its length to the point with its exquisite little flowers; numbers fully expanded, and others, perhaps not less beautiful, in the bud. We may remark here, in passing, that pretty as are the flowers to the naked eye, they are still more so under the lens. The delicate transparent wool-like processes that surround and enclose the anthers are specially deserving of examination, as, instead of being the simple hairs they appear, the glass shows their beautifully jointed or necklace-like structure. Mr. Bain informed us that the *Anagallis* was not grown in these pots with any special preparation or cultural care, with a view to increasing its vigour and development. A patch or two of it had been merely planted in these pots, together with an occasional plant of another of our loveliest wildings, *Pinguicula grandiflora*, to have at hand for botanical purposes. We should therefore apprehend that, treated specially, it would be perhaps even more effective. At all events, no one could look on it as growing in the College Garden and not admit that in it all have at hand one of the prettiest and most effective little things possible for growing, suspended or otherwise. To keep it well supplied with moisture from below would, of course, be always necessary. The little *Campanula hederacea* we also noticed growing in other pots, and its elegant appearance, apart from the consideration of its being one of the many interesting plants our country calls her own, and perhaps from agreeable associations connected with its native haunts, at once suggested it as one of the prettiest and most interesting things possible for a hanging basket.

MR. WILLIAM PAUL'S NURSERY, WALTHAM CROSS.

The county of Hertfordshire has achieved great notoriety for the very extensive cultivation of the Rose, and the production of many improved varieties of the queen of flowers. Prominently with such flowers are associated the names of Messrs. Paul, Rivers, Francis, and Lane. Not only are these cultivators celebrated for the encouragement given to the growth of the rose, but there are numerous private gardens in which the flower is extensively cultivated, so that the county of Herts has been not unjustly styled the "Rose Garden of England." But we must not be unmindful that at the present period there are other portions of this country that can compete with Hertfordshire for this distinguished position. In the raising of new varieties, we believe that Mr. William Paul occupies the foremost rank among English growers, for not only has he produced many new varieties, but it happens that they are all good. A visit to the Rose Exhibition at Kensington had kindled in me a desire to inspect the collection at the Waltham Cross Nursery; so in due course of things I started from Bishopsgate Station, and I was somewhat pleased to find that one of my fellow-passengers was a brother chip bont on the same errand as myself. We soon became mutual friends; and so absorbed were we in our conversation on the rose that we actually passed the Waltham Cross Station, the platform of which is almost connected with one of the entrances to the nursery, through a pathway in which roses are flourishing on either side. However, our mistake cost us a circuit of a mile and a half from the Cheshunt Station. Yet we did not regret the walk, as we had an opportunity of viewing the village and its surrounding objects. As yet, the progress of time has done but little towards altering the appearance of the homes of the peasantry; they still retain their primitive character—so much so, that we could not refrain from muttering to ourselves the beautiful lines by Mrs Hemans—

"The free fair homes of England,
Long, long, in hut and hall,
May hearts of native proof be rear'd
To guard each hallowed wall!"

On entering the nursery, we were most courteously welcomed, in the absence of Mr. Paul, by his manager. On leaving the spacious seed-shop, to take a survey of the grounds, the first object that confronted us was the avenue, as it is styled by the firm. It is a turf walk of noble dimensions, extending the length of the grounds in continuity, and affords a charming landscape prospect as far into the country as the naked eye can discern. The only thing that tends to mar this beautiful scene is one of those huge shafts, or tall chimneys, which is no uncommon sight in the suburban districts of manufacturing towns. Beyond this we could obtain a glimpse of the quaint old tower of Waltham Abbey Church, a spot famous for certain historical facts in connexion with the Norman Conquest.

On either side this avenue or walk were planted several unique specimens of Conifers and their allies, besides choice evergreen and deciduous trees and shrubs. They are in excellent condition for removal, having been subject to the usual system of transplanting. We must not omit to notice various species of variegated trees, some of which were exceedingly attractive, especially the remarkably white-leaved *Acer negundo variegata*. I thought as I gazed on this most beautiful species of the maple tribe, that it would be good taste to introduce this kind of tree more generally in the arrangement of our plantations, and thus produce an interesting but striking effect. No doubt, as we become better acquainted with the variegated species of forest trees, they will in time form part of the ornamental timber of our parks, and thus such trees, of which this nursery has many splendid examples, as *Ulmus campestris variegata* (the Silver Elm), and *Cerasus padus acubifolia* (the spotted-leaved Bird Cherry), will become majestic subjects of admiration for future generations. Not only the above species, but many other hardy pictorial trees, descriptions of which are to be found in Mr. Paul's catalogues, are to be met with in the borders of this avenue. We must not forget to say that, before we quitted this interesting spot, we saw growing several beds of the different sections of Zonal Geraniums, for which this nursery within the last few years has become celebrated. As there had been a heavy fall of rain previous to our visit, they were not in a fair condition for criticism.

We now find ourselves among the roses, which were the principal object of our visit; and certainly the severe winter and late frost of spring have told tales here as elsewhere. However, as my companion remarked, if you wish to judge of the qualities of the various roses there, visit them in the state in which they are growing for sale, as then you will have a capital opportunity of observing what the flower will do and what it won't do, either in point of size, thriftiness, or abundance of bloom; and if you have any doubt as to their adaptation to the locality in which you reside, then let the nurseryman decide, as he must from general practice be better conversant with their habits. Although many varieties may produce very beautiful flowers, yet they would prove but indifferent growers in or near large towns. It was really a delightful floral treat, as we strolled from spot to spot, amidst the brilliant glow of all shades of colour and their sweet perfumes. They literally loaded the breeze, and made breathing a luxury. Blooms of many of the sorts were extraordinarily large, particularly Charles Lefebvre, Alfred Colomb, Dr. Andry, Fisher Holmes, Lord Macaulay, Séateur Vaisse, Victor Verdier. The above belong to the very bright or rich carmine classes. Of the light, or those approaching white colour, we would particularize *Impératrice Eugénie*, *Caroline de Sansal*, *Madame Emile Boyau*, *Madame Rivers*, *Queen Victoria*, *Semiramis*, *Madame de Stella*. These are but a few of the many sorts that prominently attracted our attention. Of the tea-scented roses we say but little, as every one of them is acceptable for the purpose of intermixing both as cut blooms or otherwise. Of dwarf roses there is an immense quantity. Among all the classes we beheld we recognized many good old varieties that were popular favourites in days gone by.

On quitting the rose ground, we took a glance at the fruit-trees, the plantations of which cover several acres. They consist of all kinds and shapes, both pyramidal and trained trees, and they were in the best possible state of health, every care being taken to keep them clear of insects. We saw boys with brushes and pots of mixture busy washing their shoots, with a view to the destruction or prevention of vermin. The soil of the nursery being of a loamy or adhesive nature, is very favourable to the removal of trees, as it encourages plenty of fibrous roots. We concluded our visit by taking a hasty survey of the contents of the houses, one of which was full of tea-scented roses, growing in 6-inch, or 32-sized pots; and without exaggeration, I must say they were examples of first-class culture both in training and vigour. A very pretty sight to witness were tea-scented roses trained along

the rafters of the house, for the purpose of affording cut blooms. Another house was filled with some remarkably strong pot vines, some of which were bearing excellent crops. The other houses contain the usual kinds of nursery stock: in one we observed a very healthy batch of camellias. The last house we entered was a perfect blaze of bloom of the various nosegay and zonal geraniums; Mr. Paul's name being identified with the origin of many of the sorts. As the proverb says, "Time and tide wait for no man," and as we were anxious to catch the next train, then nearly due, we did not take notes of any of them; but we saw sufficient to justify us in assuring our readers that there were among them some real gems, both in regard to distinctiveness of colour and size of truss. Thus far we were much gratified and instructed by our first visit to Mr. Wm. Paul's Nursery at Waltham Cross.

JOHN. F. M'ELROY.

GRAPE-GROWING AT BANSTEAD PLACE,

THE SEAT OF GEORGE GLYNNE, ESQ., M.P.

Now that much controversy is going on respecting this important branch of horticulture, it behoves all interested in the matter to glean what they can of the *modus operandi* practised by men who stand pre-eminent as growers of this favourite fruit, and from the success which has attended the system carried out here, Mr. Breeze, the gardener, must be classed among the foremost of cultivators, being a pupil of the celebrated Hill of Keele, and subsequently spending much time in the fruit-growing localities. It is not surprising that, in spite of the up-hill work and wearying disadvantages which Mr. Breeze has had to fight against, he has acquired a name which will ever identify him with grape-growers of A. 1. celebrity. In making his borders Mr. Breeze is not partial to, in fact he sets his back to all intents and purposes against all carrion. His compost is an admixture of the following: Good top-spit loam one-half, old mortar, crushed bone, wood charcoal, and ashes, with well rotted stable dung, which are all well thrown together, mixed, and thoroughly incorporated. If outside the border, in all cases is protected from rain, thus as much command of moisture of the border is secured as a pot plant. The long rod closely pruned system is practised, and the result can be judged from the immense vigorous growths which these closely spurred rods make. The bunches of fruit are closely set down at the base of the annual shoot, with stout woody pedicels, upon which are seated finely-swelled berries of a jet black colour, and although the bunches are of immense size the arms are sufficiently strong to render them self-supporting, thus proving that a well-grown bunch of grapes, when judiciously thinned, does not require ligatures for support. Among the many sorts of grapes grown and honestly tested here, Mr. Breeze speaks very highly of the *Muscat de Saumer*. It is, he says, a fine grape, noble in bunch, delicious in flavour, and sets freely in a Hamburgh temperature. Now, being a white grape and with a Muscat flavour, this information is worth making a note of. The True Kempsey's Alicante is well done here, and proves itself to be a variety of tip-top quality. Near to the vineries I saw a superb crop of well-coloured peaches in a span-roofed house, and which should have been more prominently noticed, besides many more fine points in the cultivation and keeping of this place, but an engagement which I was compelled to keep limited my stay, and it was with much regret that I could not prolong my visit, and make a few more mems, before bidding adieu to the open-hearted, kind, urbane, and clever gardener, Mr. W. C. Breeze.

T. R. J.

THE GARDEN OF T. JONES, ESQ., WHALLEY RANGE.

Having lately made a visit to the garden of T. Jones, Esq., Whalley Range, Manchester, I trust a few remarks on some of his plants may not be out of place, containing as it does many well-managed examples of the choicer varieties of orchids. The East-India house, which is double roofed, is a model as far as construction and ventilation are concerned, and is highly spoken of by the gardener, Mr. W. Swan, contains some strong plants of *Vandas*, six feet high, well furnished with three and four breaks. *V. teres* was flowering here. *Aerides odoratum purpurascens* was good, bearing twelve spikes, with flowers of good colour and substance. *Dayii* and the short-leaved variety of noble were fine, making a pair of plants five feet high, the former with three spikes in bloom, the latter with the same number just opening; a fine branching variety of affine was also good. We saw a fine plant of the true *Veitchii*, with twenty-four leaves, having just gone out of flower, with a spike two feet long, and four laterals. Among *Saccolabiums*, *gutatum*, *giganteum*, *retusum*, and *Holtfordii* were fine plants. *Curvifolium* also, in baskets suspended from the roof, were in perfect health. *Angræcum sesquipedale* was a noble plant with twenty-seven leaves; and *caudatum* was also good, having a spike with six of its singular tailed flowers. *Cypripedium* were grown remarkably well; *Lowii*, *Stonei*, *hirsutissimum*, and *villosum* being large masses, while *caudatum*, *lævigatum*, *Dayii*, and *Veitchii* were also doing well. We saw a mass of concolor with about twenty leaves. The *Phalæopsis Ludemanniana* was still in bloom, but as we were informed, some of the flowers had been open eight weeks, they were losing some of the rich colour they had when it was exhibited at the late Manchester show. *Lowii*, of which we saw three plants, were looking well, one having made a leaf four inches long. *Dendrobium Wardii* was just coming into flower, and *D. devonianum* was also fine, with growths four feet long. *Zygopetalum rostratum* was in this house doing well, and the rare *Oncidium Krameriana* was just coming into flower. The *Cattleya* house is a lean-to, and contains some nice plants of *L. purpurata elegans*, *C. Mossiae*, *Leopoldii*, *Skinneri*, and a magnificent specimen of *Warnerii*, having nine of its large rich-coloured blooms on it. *Wagnerii* was also in bloom; *Reynellii* and *bulbosa*, in baskets, were looking well. In this house we saw a fine plant of *Oncidium sessile*, having eight leads hung up in a basket. *Pleiones* were maturing some fine bulbs. The *Odontoglossum* house joins this one, and contains some nice plants of the Mexican and New Granada varieties, all doing remarkably well; *Coronarum*, having four leads, and the lovely *Phalænopsis*, of which we saw two plants, one having seven leads, and the other eight. *Lycastes* were in this house breaking very strong, and the major variety of *Vitellium* was here, and in flower, surpassing as it does the old variety in size, colour, and substance. The *Dendrobium* house is a half span, and in it we saw some fine specimens of *nobile*, *densiflorum*, *clavatum*, *densiflorum album*; while *crepidatum* and *lituiflorum*, on blocks, were breaking well. *Calanthe masuca* was a fine plant, with twelve spikes of bloom, and

Cœlogyne cristata was also good. *Miltonias*, in pans suspended from the roof, were showing flower freely. In this house we also noticed *Eriopsis biloba* and the rare *Cattleya Dowiana*, just opening their flowers. Some fine *Lilium auratum* were in bloom in the conservatory, and a nice lot of *Azaleas* we noticed in another house, making some good growth. J. T.

Calendar.

WORK FOR WEEK COMMENCING AUGUST 10.

Kitchen Garden and Frame Ground.

CARDOONS must now be tied and banked up with earth to blanch the fleshy part of the stems. They will not be perfectly blanched for five or six weeks, so it would not be wise to delay the earthing-up much beyond this time.

LEEKs may still be planted out, and those already grown to good size may be earthed-up to blanch them.

PEAS.—It commonly happens that late-sown peas become hopelessly infested with mildew, and make no return. We have explained on several occasions how to prevent this by sowing in shallow trenches, which admit of frequently flooding them with water. Where they have been sown on the level in the usual way, they must of course be earthed-up slightly, but it would pay well for the little trouble occasioned to make a channel on each side of the row to receive and hold a liberal allowance of water.

SPINACH must be sown now for winter. The common prickly spinach is an excellent variety.

TURNIPS may still be sown to stand the winter, but it will soon be too late to sow any kind of seed for winter crops.

CELERY to be earthed-up with care after a heavy rain or a good watering; take care the mould does not get into the hearts.

MUSHROOMS can be accommodated in many ways at this time of year, as melon and cucumber frames are going out of use. Though we so often hear of failures in growing mushrooms, it is very certain that there is no esculent more easily grown; indeed, many gardeners find themselves well supplied by the spontaneous productions of dung-beds and compost yards. A mixture of turfy loam and short stable dung is to be preferred to a bed consisting of dung only. Collect the manure in a dry state, and spread it out in a shed till you have enough. Then add a fifth part of loam, chop them over well, and lay up the mixture eighteen inches thick, beating it down well as the work proceeds. In the course of a few days the bed will have a nice warmth, and the spawn may be inserted in pieces of the size of an egg. Throw over the bed a thin sprinkling of loam, and over the loam a little loose straw. Water occasionally, but take care not to make the bed wet. In the course of six weeks the crop will appear; then make up another bed to take its place, and so on all the year round.

WINTER GREENS.—This week offers the last fair and favourable opportunity for securing a sufficiency of winter and spring produce in the kitchen garden, and whatever is to be done *must* be done to make sure of supplies at a time when it is impossible to get them up quickly. Plant out every morsel of winter greens that may be left in seed-beds, or where first pricked out to strengthen, including broccoli, cabbage, kale, &c., &c. Sow collards, Red Dutch and Sugar-loaf cabbage, endive, Hammersmith lettuce, salad onions, Golden and Normandy cress, Flanders spinach, Stone turnip.

Flower Garden

CHRYSANTHEMUMS should not be topped any more, as in the event of a cool autumn those topped later than the first week in August will fail to bloom. The quickest way now to secure a few nice small plants to give two or three blooms each is to layer the shoots in pots. These late layers, if taken from the tops of strong shoots, make pretty specimens for the conservatory. In selecting the shoots for laying, take such as will make plants of good shape at once. Many ugly old plants now sprawling about to the discredit of the place might be turned to good account to supply small plants by layers.

INTERMEDIATE STOCK to be sown in pans and boxes in frames, or in some shady place under a wall. When large enough to handle, pot them for the winter, and house them in a light, dry, airy pit. A little frost will not hurt them.

LILIES.—The time is at hand when Lilies, having lately rested, begin to grow again. The brief period of rest affords an opportunity for taking them up and dividing the roots. This is the time too for making preparations for planting Lilies out of doors. There can be no doubt that all the *Lilium* in cultivation may be grown to perfection in good borders in the open ground. Those who are thinking of making a display of Lilies next year would do well to refer to The O'Shane's article on the subject in the GARDENER'S MAGAZINE of July 29, 1865.

BULBS of all kinds must be thought of in good time. If there is not a good store of stuff for potting, set about preparing it without loss of time. There can be no harm in potting a few Hyacinths and Van Thol Tulips at once.

AURICULAS require repotting to remove offsets, and secure a good bloom next season. The soil should be full of fibre, and in a sweet and fresh condition. Put the offsets in thumbs, singly, in a sandy mixture, and shut them up close for a week; this is better than inserting them round the sides of pots, as they can be allowed to fill the thumbs with roots, and then have a good shift at once.

BEDDING PLANTS to be propagated without delay for next year. To save trouble, both now and during winter, select a few strong plants of *Verbenas*, *Tropæolums*, *Petunias*, and *Lobelias*, and pot them in large pots, with one-third of drainage in the pots, and shut them up in a frame and keep shaded for a week; then let them be exposed to all weathers till the probability of frost requires them to be housed. Keep these to force for cuttings next spring, so as to be free of the necessity of propagating any of them now. The whole stock of *Geraniums* and *Calceolarias* for next year's bedding should be struck this season—*Geraniums* at once, *Calceolarias* within a fortnight—in a moist shady pit. Save seed of *Cineraria maritima*, if you want anything new in the way of silver edgings. *Cerastium* may be left out all winter, so no need to propagate that now. If thought desirable to propagate *Verbenas* now, in order to have an early bloom next year, take the points of growing shoots about three inches in length, and strike in pans of sand, and from those shift—not into pots, but into shallow boxes of any convenient form and size, in which they will winter better, and occasion less trouble in watering.

HOLLYHOCKS require plenty of water to open their top buds well, and all choice kinds on which it is desirable to have a few good blossoms to the last should be disbudded. Take off first every other bud all the way up, then remove a few more on the side farthest from the walk, on what may be called the backs of the plants, and then go over them again and remove a few buds wherever they are crowded; finally, top the stems to uniform heights, if the plants form a compartment of themselves; when they are scattered about, there is no occasion to top them.

THRIP.—Tobacco-water will do something to render the flower-buds and young tops of dahlias unpalatable to this insect, and that is the only chemical agent we can recommend. In every case where plants are infested by thrip, we consider it of the very first importance to give abundance of water at the roots; this will do wonders.

HERBACEOUS PLANTS may be divided now, and many may be raised from seed for next year. All the low-growing tufted plants, such as *Aubrietia purpurea*, *Arabis*, &c., may be parted, so that each little tuft has a few fibres; if shaded and kept watered for a week, they will soon make new roots, and form nice tufts to remove from the reserve ground to the borders and beds in early spring. It is not too late to put in cuttings of that best of all spring flowers, *Iberis sempervirens*.

Fruit Garden and Orchard House.

STRAWBERRIES to fruit next year should be planted at once, and the surplus runners finally removed from the old plants. Those rooted in small pots will want a shift; replot them *firm* in a sound loamy compost, and keep well watered.

WALL TREES may now be trained in and moderately pruned; remove the foreright shoots, and all superfluous shoots, however well placed, and train in none but good wood, and that sufficiently far apart that it may ripen perfectly.

STRAWBERRY PLANTATION.—A deep heavy loam, inclining to clay, well drained, sloping to the south, abundantly manured, and in a breezy open country, will make a good strawberry plantation. But people want strawberries where there is no such combination of favourable circumstances. Thin sandy soils may be improved by the addition of clay and manure. The soil from the bottom of a pond or ditch is the best dressing to be had in a sand or chalk country to improve the texture of the plot for a plantation, and it should be dug in to the depth of two feet if there is that depth of soil to work upon, and at the bottom of the trench should be laid six inches of half-rotten dung. This will be mellow before the roots of the plants reach it, and when they do get hold it will keep them hearty during seasons of drought, which are very distressing to strawberries planted on sand or chalk. On very stiff clays it is a folly to expect strawberries unless the ground is well drained; but with perfect drainage, clay soils lying open to the sun will produce the finest strawberries, and continue long in bearing. But greasy clays may be improved by liberal dressings every autumn with the ashes of charred rubbish, and in spring with half rotten dung. Strawberries may be obtained in good seasons in tolerable abundance from almost any kind of soil or situation, but the precariousness of the crop, and its inferiority both in quantity and quality when placed under unfavourable circumstances, are sufficient reasons for the exercise of discretion and spirit in the culture, for when liberally treated there is no plant in our gardens that makes a better average return on outlay than the strawberry. Therefore it is we advise the grower never to plant under trees, to dig and manure without stint, and to lose no reasonable opportunity of improving the plantations.

PLANTING STRAWBERRIES.—It depends so much on the state of the plants whether it is well or ill to plant at this or that season, that no definite rule can be laid down. We wish to be distinctly understood on this point. We have planted strawberries in every month of the whole year without accident of any kind. Well-rooted plants can always be lifted with good balls when they are simply to be moved to another part of the same garden, and plants in pots can always be turned out without breaking the balls, even if loaded with fruit without injury. But when the plants are taken up in nurseries, much of the soil shaken from the roots, the plants then packed for transit, perhaps exposed in a London seedman's window before being sold, there will be so much exhaustion that the plants must have time to recover before they can fruit satisfactorily. Therefore, those who plant stock supplied from a distance had best plant in August or September; if the plantation is made in spring, February is a good time to plant, as the plants have still time to make roots before fruiting; but if obtained in pots they may be put out at any time. Plant at distances suited to the habit of the variety. Such as British Queen, Nonpariel, Goliath, require to be two and a half feet between the plants, and the rows three feet apart. Varieties less robust in habit, such as Black Prince, Wellington, Comte de Paris, &c., one foot to eighteen inches between the plants, and two feet from row to row. All the varieties will bear well at less distances, but the distances we give will pay the best in the end, for the rows can be stirred and manured conveniently, and the free circulation of air amongst the plants will give the fruit its full size, colour, and flavour. We see everywhere crowded plantations, and we never ask about the result, knowing that the possessors of those plots have really no clear idea of what strawberry plants should produce with good culture. *Plant firm*, water liberally if the weather is dry, and continue till rain comes. If possible, plant when there is a probability of rain following, and in any case of planting during hot sunny weather cover the plants with large inverted pots from ten to five every day, and always leave them uncovered at night. Dispense with the shading as soon as possible, and if possible remove the pots during cloudy or showery weather.

Greenhouse and Conservatory.

CAMELLIAS must be looked over at once. Many old plants will be found wanting water, and the best way to deal with them will be to plunge the pots to their rims in a tub of water for half an hour, to thoroughly soak the ball through. If allowed to continue very dry now that their buds are set, the buds will fall off. Young plants that have not quite filled their pots with roots must be only moderately watered.

HARD-WOODED PLANTS that have been exposed to all weathers in pits and plunge-beds, and in the flower garden, must shortly be returned to their proper places in the greenhouse for the winter. It is not that there is any fear of frost just yet, but we may have long-continued and chilly rains, and these plants ought not to be exposed to such vicissitudes. At all events, where plants of any value, as *Epaeris*, *Boronia*, *Correa*, &c., are now out of doors, let the first cold rains that occur be the signal for housing them.

CINERARIAS will in many cases need to be shifted on, and it is well to take advantage of the forward state of some of the plants to obtain a few

extra fine specimens by encouraging vigorous growth. Starvation and fly go together in the cultivation of the Cineraria. Keep the stock sufficiently watered, and use a good holding compost, and there will not be much fly.

GREENHOUSE to be cleared out and cleansed, and if needful repaired and painted, and made ready for re-stocking. All wood-work and brick-work should be scrubbed, and the latter lime-whited, and all holes stopped with cement. This process will clear away vermin, and do much to prevent mildew and other plagues in winter. If painting and glazing are not done at once, the house may have to be re-stocked before the effluvia consequent on the operation has been dissipated, and losses of plants will be the result.

LAOENALIA TRICOLOR.—Amidst the numerous varieties of bulbous-rooted plants that adorn our greenhouses during the earlier months of the year, few deserve or are better entitled to the gardener's attention than the one named above. Their beautiful spikes of trumpet-shaped red and yellow coloured flowers, wholther intermixed with other plants or otherwise, are sure to be attractive. Unlike the hyacinth, narcissus, &c., they do not require to be purchased annually that sound and good flowering bulbs may be secured, as the Lachenalia increases every year in number and strength, if the grower will bestow some degree of care. It is time now to turn them out of the pots in which they flowered in the spring, and to repot them for next season. In sorting them the stronger bulbs are selected, and five of each planted in a six-inch size pot, commonly known as 32's. Good drainage and clean pots are indispensable. They thrive best in a strong loam (not clayey), but of a silky or soft texture; add to this about a fourth part of dry rotten manure, with a little sand. If the manure be decayed cow-dung, so much the better, provided it is free from worms. They should be placed in a cool pit, the object being in the present stage of their growth to check too rapid an evaporation in the soil, as frequent waterings when there is not an abundance of rootlets to absorb the fluid is an injury alike to the plant and the soil. When they have begun to vegetate freely, expose them more fully to the light and air; their rich dark green speckled leaves will then soon begin to strengthen in growth. That a healthy vigour may be preserved during the winter months, place them on the upper shelf of a greenhouse, near the glass, but do not neglect carefully watering them. As the flower-spikes become perceptible, allow the pots as much room as your means will admit of for the display of their vigorous foliage. During the blooming season, shade on hot sunny days; this will preserve the colour as well as the flowers. When they have ceased blooming, gradually ripen the bulbs by reducing the quantity of water, till you wholly discontinue the supply, when they may be put in any corner of the greenhouse till the period of disturbing them as above recommended. The offsets or smaller bulbs may be planted, ten or twelve or more in number, according to their size, in a five-inch or 48-sized pot; they will not all flower, yet you may increase your stock of strong-flowering bulbs for selecting from in the ensuing season. The Lachenalia will submit to be forced, but it is at the expense of weakening both the bulb and the flower-spike.

Stove and Orchid House.

CLIMBERS will in many instances need to be cut back in order to obtain an immediate and quick growth to produce a late bloom.

ORCHID HOUSE requires now some revision, so as to separate plants that are going to rest from those that are still actively growing. Encourage growth in young specimens recently potted, but as the growth of any orchid appears to be completed gradually withhold water, and remove them to a cooler part of the house.

STOVE PLANTS must be prepared betimes for the winter by gradually withholding water from such as have completed their growth, and exposing as much as possible to air and sunshine all hard-wooded plants, that the growth of the season may be completely ripened. Shut up early and use fire-heat if needful.

ORCHID HOUSE.—Orchids in full growth must have moisture and heat sufficient to maintain them in health, but the judicious cultivator will not often have to light a fire this month. Those going to rest to be encouraged by removal to a cooler part of the house, where they must have less water, but be kept plump by frequently sprinkling the paths and stages. This is a good time to separate pseudo-bulbs for increase of stock, and to pot on small plants. Orchids that have been a long time in the same pots need top-dressing with fresh material. Shut up at four till the third week of the month, and then shut up at three. After shutting up, syringe gently with water of the same temperature as the house. Temperature of Indian house, 70° to 75° by night, 75° to 85° by day; Mexican house, 65° to 70° by night, 70° to 85° by day.

Orchids that may be in bloom in August.—*Aerides nobile*, *Quinquevulnerum*, *quinquevulnerum album*, *suavissimum*; *Angrecum caudatum*; *Arpophyllum cardinale*; *Bolbophyllum Henshallii*; *Barkeria melano-caulon*; *Brassia Lanceana*, *Wrayii*; *Broughtonia sanguinea*; *Burlingtonia Knowlesii*; *Calanthe Dominii*, *furcata*, *masuca*; *Cattleya amabilis*, *candida citrina*, *crispa*, *crispa superba*, *granulosa*, *Harrisonia*, *Harrisonia violacea*, *labiata pallida*, *Lemoniana*, *Loddigesii*, *Mossia*, *Schilleriana*, *violacea*; *Coryanthes maculata*, *Cycnoches Loddigesii*, *ventriosum*; *Cymbidium pendulum*; *Cypripedium barbatum grandiflorum*, *Lowii*; *Dendrobium calceolaria*, *sanguinolentum*; *Dendrochilum filiforme*; *Epidendrum Phœniceum*, *vitellinum majus*; *Galeandra Bauerii*, *cristata*; *Miltonia bicolor*, *spectabilis*; *Mormodes citrinum*; *Oncidium divaricatum*, *pulchellum*, *pulvinatum*; *Peristeria elata*; *Phajus albus*; *Phalænopsis amabilis*, *grandiflora*; *Promœna stapeloides*; *Saccolabium Blumei*, *furcatum*, *guttatum*; *Sobralia liliastrum*, *macrantha*, *macrantha splendens*; *Stanhopea aurea*, *Devoniensis*, *insignis*, *Martiana*, *oculata*, *tigrina*, *tigrina lutescens*; *Trichopilia picta*, *Vanda Batemanni*, *Roxburghii*, *teres*.

Forcing Pit.

PEACHES and NECTARINES under glass should now be fully exposed night and day by removal of the lights. Thin out the young wood of the season, to promote the ripening of all the good shoots that have been laid in. The borders in which the trees are planted may be allowed to get comparatively dry with advantage.

VINES from which the fruit has been cut will be better if treated the same as advised above for peaches. If the lights cannot be removed, open all the ventilators night and day, and slightly reduce the number of laterals. Vines in pots to be laid on their sides as soon as the leaves wither, in order to induce a state of complete rest.

PINES in a growing state to have a moist air and a steady bottom-heat. Shut up early, and at the same time sprinkle the bed; this will greatly help any fruit now swelling. The bottom-heat for pines must be not less than 90°.

CATALOGUES.

AMB. VERSCHAFFELT, RUE DU CHAUME, GHENT. *List of Palms, Cycads, and Pandanus*, with prices.—An excellent list for purchasers of conservatory plants. There is added a list of selected novelties of various kinds.

DILLISTONE AND WOODTHORPE, SILLE MEDINGHAM AND BRAINTREE, ESSEX. *Catalogue of New and Choice Plants of 1867*.—In this catalogue the novelties of the season are offered at low rates. The system adopted is a sort of horticultural express. The novelties sent out by the great houses in the spring are purchased, and multiplied, and made ready for distribution in time for amateurs to buy them cheap the same season they are sent out.

WILLIAM ROLLISON AND SONS, TOTTING, SURREY, S. *Catalogue of Stove, Greenhouse, and Hardy Ferns*.—A first-rate list full of interesting and useful notes, the classification sound, the printing beautiful, and the book well adapted to keep at hand for reference, wherever ferns are cared for. A pleasing feature is the announcement that "the present catalogue has been prepared by our manager, Mr. Wilbraham Buckley." Mr. Buckley once did us a service; we asked him for a few van-loads of plants for an exhibition got up for a philanthropic object, and he gave them in a ready and generous manner. It is agreeable to find by this book—for it is a book—that he is as good at ferns as in acts of benevolence. Bravo, Buckley!

HOOPER AND CO., COVENT GARDEN. *Price List of Ferns, Hardy and Exotic*.—A short comprehensive list, prepared for ready reference, and comprising all the good ferns in cultivation.

Replies to Queries.

J. R.—The seedling nosegay is full of promise, though we have in Christine Nosegay, Pink Stella, Rose Rendatler, and some others, good varieties of the same class, though we believe none of precisely this shade of colour. Think a second time about the name you propose. It would be advisable to cut up the plant at once, and make stock, and next year bed it out to prove it, for pot culture is but a partial proof of a variety of this type.

Sizes of Flower Pots.—Colman.—The London potteries follow what is called the "Chiswick Standard," the name and sizes of which are as follows: Sixties, 4 inches deep, 3 inches wide at top; forty-eight's, 5 inches deep, and 5 inches wide; thirty-two's, 6 inches deep, and 6 inches wide; twenty-four's, 8 inches deep, and 8 inches wide; sixteen's, 9 inches deep, and 9 inches wide; twelve's, 10 inches deep, and 11 inches wide; eight's, 11 inches deep, and 12 inches wide; six's, 12 inches deep, 13 inches wide; four's, 13 inches deep, 15 inches wide; two's, 14 inches deep, and 18 inches high. "Uprights" have gone out of fashion; probably the last seen of them at exhibitions was when Mr. William Paul presented his first lot of hyacinths in them, and people thought he had taken to chimney-pots. We have for some time past been using for specimen plants that do not require a great depth of root-room a superior style of pot, made for us by Messrs. Adams Brothers, of Belle Isle; they are made of the best clay, and with more than ordinary care, and are intermediate in proportions between pots and seed-pans. The most useful size for small specimens, and one admirably adapted for ferns, is one measuring 9 inches deep by 15 inches wide.

Tree Ferns, &c.—G. M.—When your tree-ferns and grass-trees arrive from New Zealand, put them in an upright position in some cool, close, rather dark place, such as a shed, or under the stage of a greenhouse, and syringe them once a day for a week. The next week syringe them two or three times a day, and protect them against draughts of air, so as to keep them constantly damp. In about three weeks after the date of their arrival they will begin to show signs of growth; they may then be potted. In preparing them for pots, cut clean away all hard, dead, wiry roots, so as to reduce their stumps considerably. It is seldom, however, that there are any roots left to cut away, they are so closely trimmed before being packed for transit. The best soil is one consisting wholly of tough fibrous peat, with plenty of sharp sand. When the crocks are placed, lay over them some rough charcoal, then pot the trees in the usual way, and fill the stuff in as firmly as possible. Put them in as small pots as possible; it is easy work to shift them on as they grow, and it is a great help if the roots soon touch the sides of the pots after they begin to grow. Do not make the soil wet at all until the growth has advanced somewhat; to keep it regularly damp will suffice, but continue to syringe the stems frequently, as the moisture absorbed that way will soonest arouse the energies of the plants. It is a matter of choice whether you take up the hyacinths. They will do very well as they are.

New Subscriber.—Yes, one strong industrious man may do the work, but it is full as much as any one man can do.

Propagating Bedding Plants.—Novice.—The common soil is now like a hotbed, and almost any cutting, even if badly taken and badly inserted, will strike roots if covered with a bell-glass. The way to learn propagating is at once to begin practising; even if you fail at first, you will soon learn why it is, and will soon after succeed. As a rule, any bedding plant may be propagated now by taking rather young, but not the youngest shoots, and cutting them to a length of two or three inches, removing one or two of the lowest leaves, and then planting them firmly in sandy soil, and covering with a hand-light or bell-glass. Look at them once a day, and at the same time sprinkle them with water. A common frame or a raised bed of earth now becomes a hotbed if kept shut, and any amount of propagating may be done by means of a frame and a raised bed surfaced with four to six inches of sandy soil.

Books.—J. S., Staplehurst.—So far as we know, Withering is obtainable only of the second-hand booksellers. It is a long time since we saw it announced as a trade book. Grindon's "British and Garden Botany," published by Routledge, price about 12s., is admirable as a help in determining the names of British plants, and withal a most interesting and instructive work on plants generally. Deakin's "Florigraphia Britannica," in four volumes, published by Groombridge and Sons, is a most valuable work, not much known, and perhaps not fully appreciated. Considering the abundance of plates, and extent of the work, it is cheap, the price being about £3 10s. The grand book on British plants is that by Professor Syme, published by Hardwicke, of Piccadilly. It is costly, but there is nothing to equal it. Bentham's "Handbook of the British Flora" should be in the library of every student of British botany. There are two editions, one at 12s., the other (with engravings) at £3 10s., published by Mr. Lovell Reeve.

John Redshaw, Bourne, Lincolnshire.—Your ivy-leaved geranium is extremely pretty. It differs from *L'Elegante* in its more decided creamy

edge. The plant is of vigorous habit, very bright and pure in colouring, and will make a fine edging plant to serve just such a purpose as *Manglesii* is so much valued for.

Delphinium Seed.—S. B.—If you wait till it ripens on the plant you will lose the greater part. The way we save it, and obtain it all, is to take a dry bell-glass, and stand it open end upwards, on a flower-pot in a sunny greenhouse. We cut the seed-stems just before they burst, and put them in the bell-glass. The sun finishes them, and the seed is all shed into the clean glass, and is ready for use. Sow at once if you want strong plants.

Paxton Manure.—Constant Reader.—We really know nothing at all about it. The manufacturers of such things should advertise them. You might, no doubt, soon revive your lawn by the occasional application of a thin sprinkling of guano or saltpetre.

THE LATE MR. JOHN NITCHELL.

We have to record the death on the 17th ult., at Enville Cottage, Addlestone, Surrey, of Mr. John Nichell, at the patriarchal age of 83, the oldest English royal gardener, having been connected for more than fifty years with the royal gardens of Kensington and Kew, and lastly the Royal Lodge and Cumberland Lodge Gardens in Windsor Great Park. During the half century he served with strict integrity four monarchs: viz., George III., George IV., William IV., and lastly, our beloved Queen; who, as a reward for his long and faithful services, about ten years ago allowed him to retire, at the same time granting him a liberal pension for life. After this he settled down on his freehold, known as Enville Cottage, Addlestone, which was the place of his last earthly abode. The name of Enville Cottage was given to it by him from his early associations with Enville Gardens, at which place he served his apprenticeship, about the time the well known Enville pine-apple was introduced there. From thence, in quest of further horticultural knowledge, he came to London, and worked for some years in the then celebrated gardens of the Earl of Tankerville, at Walton-on-Thames. From there he, to obtain further improvement in the science or art of gardening, entered the Royal Gardens at Kew; from which place he was selected by Mr. Aiton to conduct all the gigantic improvements then in progress and contemplation at the Royal Lodge and Cumberland Lodge Gardens, where the largest vine in England is now growing, in Windsor Great Park. At the same time the island on which the fishing temple at Virginia Water is erected was being embellished under his direction, as was the formation of the celebrated *ruin* and magnificent drives in the locality of that enchanting spot, Virginia Water, one of the most picturesque *minor* lakes in England, the whole of which was carried out under his direction, during which operations frequently as many as 110 to 120 men have been employed by him, many of whom have ranked, and those left behind soon to follow him do rank, as horticultural celebrities, and who must ever owe him a debt of gratitude and profound respect, and entitle his memory by them to be revered with filial honour and affection, not only for his parental kindness to them, but for the scientific and practical information imparted and advice inculcated; and, last of all, though not least, for the position in life they at present fill and enjoy. Among many now living recipients of his kindness, I may enumerate Mr. John Mann, manager of Hyde Park, St. James's Park, and Kensington Gardens; Mr. James Drewett, of Denbies, the renowned Muscat grape-grower; Mr. J. W. Thomson, formerly head gardener to the Duke of Northumberland at Syon House; and many others of equal celebrity too numerous to detail on this occasion; and although a very strict disciplinarian as an employer, his urbanity and kindness made him respected, not only by those placed under him, but by every other person who had the honour of his acquaintance. Therefore he has gone to his last abode not only full of years and honour to his name, but beloved, regretted, and respected by all who knew him; and I fervently pray that the all-wise Disposer of events, in His mercy and love for us unworthy sinners, has received his immortal spirit into His everlasting kingdom, as a reward so just and honourable a man merits. He was interred in Addlestone churchyard on the 23rd ult., followed by several friends, among whom was Mr. J. W. Thomson, he being the only horticulturist connected with royalty present. The name of Nichell is rather uncommon, and by his death the name and family becomes extinct, as no member is now known to exist.

Correspondence.

VARIEGATED PELARGONIUMS AT BURY.—I am one of the many persons who were started by the decision of the judges on this portion of the exhibition at Bury. It begins to be evident that justice will not be afforded in the quarter we might have looked to, and *did* look to for it, and we appeal to you. Possibly you will ask, and if so, properly so, for the case to be stated. Very well. The schedule invited competition in 12 Seedling Pelargoniums of 1866 or 1867. The schedule did not state by what standard they were to be judged, nor did it demand clean plants. But I, in common with many other cultivators and raisers of these things, took it for granted that the plants should be shown in a *complete state*; that is to say, clean, with none of the original green leaves: in other words, variegated throughout from top to toe, and that any of the original green leaves on any one plant would disqualify the collection containing it. Our surprise was great to find the cup awarded for a collection in which green leaves were plentiful, the plants bearing such leaves being in the condition of the first break from the crude seedling state, and only as yet *promising what they might be*, and worthy to be commended, and *no more*. Had all the competitors brought plants with green leaves, the judges might have felt bound to decide upon their merits; but they had "ample room and verge enough" to put the first prize lot out of the competition, and give as their reason for doing so the word "Unclean." I put it to cultivators and exhibitors generally whether, in a competition in a class (of any kind of plants) in which the flowers should be double, varieties bearing equal quantities of double and single flowers would not be disqualified? Or, to come closer, how would it be in an ordinary class for variegated pelargoniums, if a first place were given to a group showing abundance of green leaves? If there were competing collections in the class wholly variegated, and in any way worthy of consideration at the same time, those with green leaves would surely have the lowest place, or be thrown out altoget-

ther. We decline—we have agreed to decline—taking into consideration the merits of Mr. Grieve's plants in respect of their variegation, for the simple reason that their unclean state condemned them, and we are prepared to submit the case, on this ground alone, to cultivators, exhibitors, and judges universally, save and except those who constituted the jury in this class at Bury, and who framed a special code of judging for this special case. Let it be distinctly understood, there is no personal feeling in this complaint. Mr. Grieve deserves and is the subject of universal respect. To him we are indebted for the first start in this glorious race, and if he had won the cup by means which none could question, we would rejoice in such an addition to his many well-won honours. It is in behalf of fair-play alone that we wish, through the GARDENER'S MAGAZINE, to say that, while we protest against the award of the cup to Mr. Grieve because his plants were not clean, we firmly believe it should have been given to Messrs. F. and A. Smith, of Dulwich, whose collection was superb in every respect, and not a green leaf visible amongst them. It is a singular circumstance, too, that Mr. Grieve should have in his possession several strong plants of at least one (if not more) of the varieties shown as seedlings of 1866 and 1867. He must have made hay while the sun shone, and when it did not shine. But let that pass; the Bury cup was given for imperfect plants, and it cannot surely be a gratifying circumstance for its possessor to win it by such a fluke. If it was predetermined that the cup should not leave Bury, a notification to that effect should have been made, and *some other* sort of thank-offering might have been given to Mr. Grieve without injury to any of his competitors. I sign this, for myself and friends,

ASTONISHED SPECTATOR.

GRAFTING VARIEGATED PELARGONIUMS.—Three years ago you suggested that the weak-growing varieties of tricolors should be grafted on vigorous seedling stocks. I at once took the hint, and worked a considerable number. I find that the weak kinds are greatly assisted by the foster roots, and I believe that many kinds that are being extinguished because of their lack of vigour might be kept if they were cultivated in this manner. But we are fast being supplied with varieties possessing vigorous constitutions, and it is at once the simplest and most satisfactory mode of procedure to have them on their own roots, so that for ordinary purposes grafting may be allowed to pass into desuetude. I observe, in the Calendar of Operations in the Magazine of July 27th, you remind us again of this process, and it has occurred to me to drop a line in praise of it for quickly producing standarda. These make grand conservatory plants to group in the rear of dwarf palms and ferns, the tricolors especially having a fine effect when thus lifted up and shown in the aspect of trees with fine round

Fig. 2.

Fig. 1.

heads rich with colour. Your original hint has been largely taken, and I have no doubt many gentlemen's gardeners and amateurs would follow it if they saw the way clear to succeed. The process is extremely simple, and the two sketches which accompany this explain it fully. Take tall stocks of any kind—seedlings are to be preferred; cut off a considerable proportion, but not the whole, of their top branches, and selecting a suitable part of the head, split it as in fig. 1. Prepare the graft to fit the cleft; let it be small, half ripe, and with three or four healthy leaves; tie it and clay it as in fig. 2, and keep it shut close and warm, and it will unite almost immediately. As the graft takes the sap, remove the wild growth—that is to say, the growth of the stock—by degrees, but be not in haste about it; and when the graft has made a fair start untie the bandage, and if the junction is good leave it uncovered, but put a stick to which the head must be tied for security. If the junction is not a good one tie again with soft bast, but do not clay it. As for the rest, every one who can grow a pelargonium at all will know what to do to make these into handsome plants.

R. B.

PROPOSED EXHIBITION OF TRICOLOR GERANIUMS AT KENSINGTON.—Having been invited to compete in the show proposed to be held in September next, I have declined for the following reasons: Exhibitors are to find the money, the plants, and the time; they are thus to contribute directly to the resources of the R. H. S., and gain less than they give, if they gain at all, and be at the mercy of any judges that a tribunal over which they have no control may appoint for them. Let the Society find the money for an exhibition that must be much more to its benefit, if benefit at all, than to any of the exhibitors. It is a capital idea of the one-sided sort to ask a man to subscribe £5 for a chance of winning £2 or £3, and with no voice at all in the appointment of the jury on whom his fate will hang. The last show of the kind was a failure; had it been otherwise, I presume our faithful Magazine would have reported it. The Bury competition has given rise to an unpleasant discussion, and there is at least one good reason for discontent. Surely the new proposal will meet with but small support, and men who value their money, their plants, their time, their reputation, will keep away from it.

ONOR. BRT.

SUBSCRIBERS TO THE GARDENER'S MAGAZINE who desire to extend its sphere of useful news, and are willing to interest themselves in promoting its still wider circulation, can materially further this object by sending to the publisher the names and addresses of persons they think are likely to become subscribers, who will forward to each a SPECIMEN COPY free. A stamp must accompany each name and address sent, to cover the postage of the specimen copy.

The Gardener's Magazine.

SATURDAY, AUGUST 17, 1867.

THE ZONAL PELARGONIUMS HAVE ACQUIRED SO HIGH A DEGREE OF POPULARITY, that we may safely affirm that as a class they take precedence of all other soft-wooded plants that are grown in collections, and that are especially encouraged at exhibitions. There are many good reasons for the favour shown them by the horticultural public, and most prominent amongst their claims to favour we may notice their variety of colouring in leaf and flower, their excessive gaiety of appearance, their general adaptation to the embellishment of the garden, and the certainty with which they may be grown and kept with only the most ordinary appliances and commonplace skill. To grow a specimen heath may be the work of ten years, during which the plant may be subjected to many accidents; to grow a specimen pelargonium is the work of three years at the most, and in two years a showy plant may be produced with but a tithe of the trouble the heath would demand to make it equally good of its kind to the pelargonium. We must grant that in every stage of the proceeding the heath is the more noble object of the two, and we would be the last to discourage the cultivation of hard-wooded plants: for we do not wish to see gardens and plant houses occupied with pelargoniums solely. Nevertheless, amongst the thousands of persons who enjoy the recreations of horticulture, those who have time and means to grow hard-wooded plants are few; those who can grow such plants as pelargoniums, and especially those of the inquinans section, are many. It is therefore quite the proper thing to countenance and encourage the increasing passion for collecting and cultivating, and we may add, too, the breeding of zonals of every class, for there is room for improvement yet, and variety in this department is as charming as in any other.

We have endeavoured in our "Geranium Papers" to set forth from time to time standards of perfection for the various classes, and have instituted comparisons amongst the varieties, with a view to assist our readers in the selection of the best. We wish now to make a few observations on the position of this class of plants at exhibitions, for that appears to be anything but satisfactory. The best displays of specimen plants we have seen this season were those shown at the concluding exhibition of the Royal Botanic Society. A few of the leading cultivators of specimens alone appear to have hit upon the mode of treating these plants, to produce compact symmetrical heads, with abundance of fresh flowers and fresh leaves, and with no display at all of sticks and ties. In most other classes of plants a certain average goodness has been attained by cultivators everywhere, above and below which the plants are found at exhibitions, but seldom far away from the average. With the zonals it is otherwise. We see in one case, as in that just cited, examples that surprise us by their splendour, and at the very next exhibition we visit we find examples that are literally unfit for show, bad in themselves perhaps as varieties, and made worse by the very worst of treatment. A plant that grows so quickly, that flowers so surely, that needs little else than sunshine to bring it to perfection, ought to be more fairly dealt with for purposes of exhibition; and we do hope that promoters of shows will give attention to the subject in the preparation of their schedules.

One of the most prevalent of mistakes is the growing of specimen plants of varieties that are adapted only for bedding. Such sorts as Tom Thumb, Stella, Christine, Madame Barre, and others that are favourites for beds, are quite unfit to be trained out to a huge size as exhibition subjects. However well done, they convey to the public a quite false impression of the capabilities of these plants, and tend to falsify the tastes of amateurs, who are too often led astray by mere colour, regardless of the higher claims of form in exhibition subjects. Yet there is no lack of varieties with flowers that approximate closely to the ideal standard of perfection, and in every conceivable variety of colour, pure blue and pure yellow alone excepted. With such varieties at command as Madame Werle, Amelina Grisau, Dr. Lindley, Prime Minister, Tintoret, Andrew Marvel, Magna Charta, Beauté de Suresnes, and others of the highest quality and the most tractable dispositions, it is lamentable to see the energies of the specimen cultivator devoted to the very worst that can be found for the purpose he intends them for. Concurrently with errors of selection by the cultivator, we must take

into account errors of schedules and errors of judges, to get at the whole reason for the generally unsatisfactory position of the Zonal pelargonium as an exhibition subject.

In the preparation of schedules, it would be well in future to consult the system of classification proposed in No. XL. of the Geranium Papers (July 27, 1867). That is at once simple, practical, and self-explanatory. Many varieties might be placed in more than one of our nine classes, and judgment will be required to apply these rules. But judgment is always needed in the application of rules, so ours are no exception. In the preparation of a schedule, sections may be appropriated for all nine classes separately, or several of the classes may be combined. We may include under one section, class 1 (green), 2 (zoned), 3 (nosegay), and 9 (double-flowered), and a dozen plants comprising examples of these four classes, might constitute an effective group. Again, we may include under another section, class 4 (variegated) 5 (golden-leaved), 6 (bronze zonals), 7 (gold zonals), and 8 (silver zonals). This division of the whole into two classes places all green and dark-zoned leaves in one, and all variegated and coloured leaves in another. Another and better arrangement would be to make three sections thus: Section 1 to comprise green, and zonal-leaved, and double-flowering varieties (classes 1, 2, and 9); section 2 to comprise variegated, golden-leaved, and silver zonales (classes 4, 5, and 8); section 3 to comprise bronze zonals and gold zonals (classes 6 and 7). There is no schedule so limited that it cannot make room for three sections of zonal pelargoniums, more especially as these plants are at their best when the provincial exhibitions usually take place. Enlarging the scheme, we may make four sections, thus: section 1 to comprise Green-leaved, Zonal, Nosegay, and Double-flowering; section 2 to comprise Variegated and Silver zonals; section 3 to comprise Gold-leaved and Bronze zonals; section 4 to comprise the Gold zonals alone. This last arrangement is undoubtedly the best, and it is promotive of harmony of colouring and character in the several groups.

The outcry made by some of our friends against the multiplication of varieties we confess we are deaf to for the present. It is recorded in history that every favourite of the florists has been prolific of varieties. The florists insist upon having plenty to choose from, and each adds to the sum-total by the pastime of raising seedlings. There are tulips beyond number, and some are very much alike. It is the same with pinks, pansies, auriculas, and the rest of the favourites. It must be the same with the zonals, for the merest tyro can raise seedling plants, and out of any batch from well-saved seed some good ones are pretty sure to occur. It must be borne in mind, too, that the practised connoisseur will see differences between varieties that to the uninitiated appear to be identical, and we are surely not required to rob the connoisseur of the refined pleasure of detecting differences where the untrained eye can discover none. We may find two tulips so nearly alike that the novice, if caring about either, would as soon have one as the other; but the amateur *par excellence* would perhaps value one of the two at twenty pounds and the other at twenty pence. It is the same in other things, and will ever be so while shades of difference give the key to relative values. But there is something more to be said on this subject. Zonal pelargoniums, in common with many other attractive subjects, do not show all their characters at first. We may take, say, a dozen tricolors (Gold Zonals) that are very nearly alike, and preserve one, and destroy all the rest. In so doing we may really preserve the worst and destroy the best; and some of them may be so far the best that, if preserved, our first selection would be found to have been quite in error. When, therefore, floral committees and judges at exhibitions take upon themselves to say, "We must put a check on this multiplication of varieties by limiting the number of our certificates," they act absurdly; for they step out of the judge's seat into that of the legislator, but bring to their new office none of the legislator's wisdom. It is not for judges to pass by good things, and treat them with contempt, because they have certain notions about the number of varieties that should be allowed. Their business is to deal with things they see according to merit, without attempting to forecast their fate, or dictating to the public what it shall accept or reject. If a cultivator were to present 50 varieties of tricolors to a tribunal existing for marking relative merit, and they were all thought deserving of honours, they ought to have them. It may then be left to cultivators to determine which of that 50 should be received with favour. We are not ad-

vocating the increase of certificates, for perhaps there are too many granted already; but we think it proper to suggest that judges should limit their energies to the task they are appointed for, and avoid, on the one hand, discouraging men who have laboured earnestly and brought forth good fruit, and, on the other hand, attempting to shape out the fashions of the future; for the law of fashions and popular tastes is something too subtle for individual influence, and even for the power of guidance that may be supposed to reside in imposing tribunals.

ST. MATTHEW'S, DENMARK HILL, COTTAGERS' FLOWER SHOW.

The exhibition held in connexion with the St. Matthew's Working Men's Institute, in the schoolroom, Camberwell New Road, on the 1st and 2nd of August, was an interesting affair of its kind, and calculated to be eminently beneficial in promoting the practice of floriculture amongst the working men of the district. The exhibition was considerably above the average of what are usually called "cottagers'" shows, and this for a district so closely connected with the great metropolis is a fact of some importance. There were some fine plants contributed by gentlemen's gardeners, a very showy series of designs for flower gardens on a large scale coloured with cut flowers, several beautiful fern-cases, and a fair collection of greenhouse and window plants, in which of course geraniums, fuchsias, and ferns were conspicuous. As an experiment, we consider it highly satisfactory, but we hope that future exhibitions in the same place will have greater help from the gardeners of the district. What the gardeners did for it was well done, and the best thanks are due to those who cheerfully lent their aid. But it is desirable that the gardeners should do more, for cottagers' productions in a London suburb are of necessity lacking in attractiveness for the general public, and the skilled cultivators are wanted to give character to the affair by means of a superior class of productions, which not only serve to gratify people who pay for admission, but assist the more humble amateurs by setting before them models for their imitation and guidance. The best group of decorative plants in the room were furnished by Mr. Smee, gardener at Redpost Hill. This group comprised grand examples of the very striking *Solanum purpureum*, *Pandanus Javanicus variegata*, *Maranta capitata*, fine; *Boehmeria argentea*, *Dracena ferrea*, and a fine *Croton*. Mr. Foreman, of Denmark Hill, was placed second with *Anthurium leuconeurum*, *Cissus discolor*, *Cyanophyllum magnificum*, *Croton pictum*, *Maranta Porteana*, *Cyperus alternifolius*, about half green and half variegated, in size and contour a very fine plant. Third, Mr. Kent, gardener at Grove Vale, East Dulwich, with *Dracena Cooperi*, *Caladium Cannertii*, *Sansiveria Javanica*, *Solanum purpureum*, *Caladium bicolor picturata*, *Ananas Pernanganensis variegata*. These noble plants made a rich bank at one end of the room.

The designs or "model gardens" were all good, but the one to which the first prize was awarded was one of the best it has ever been our lot to meet with at a show, for these things as a rule are tawdry and tasteless. Mr. Chapman, of 7, Cold Harbour Lane, was the exhibitor of this, and took the silver medal deservedly. The design comprised a terrace with steps down to a spacious oblong lawn with walk all round, and ribbon borders for boundaries. The grass turf was beautifully produced in an even surface of green flock paper, such as is used by paperhangers, and a few flower-beds very brightly and tastefully coloured. Mr. Blake, of Denmark Hill, stood next, with a good scheme for a terrace and grass ramps, with plenty of colour. As a design this was good, for it could be carried out in practice, but the getting up was rough. In the next place stood Mr. Hall, of Wellington Row, with a formal geometric garden of the carpet school of colouring. The judges commended a design from Mr. Murray; this was a good carpet pattern, with too much colour. Mr. Windsor contributed a large and gaudy scheme, which was very roughly got up, and so overloaded with colour that it was far from agreeable to look upon it even for a moment. In an amateur class for designs, Mr. Delhaye stood first with no competitor, but it was a rather tame and decidedly rough affair, made worse through the introduction of a pool containing gold fish, the animals being too large for their lake.

In the class for specimen plants there were some excellent fuchsias. The first place was awarded to Mr. Chapman, for a fine bush of *Venus de Medicis*, rich with flowers and fresh in leafage. Second, Mr. Jenkins, of College Street, who had a beautifully finished standard *Marquis of Bristol*, the large leaves and large flowers of which were eminently creditable to the cultivator. Mr. Meatham third, with a nice pyramid *Venus de Medicis*. There were also shown in this section a good *Carmine Nosegay* geranium, and a small standard *fuchsia, Venus de Medicis*.

Groups of miscellaneous plants, arranged for effect, were numerous. Mr. Chapman made an interesting group of large fuchsias, geraniums, and other useful plants. The fern-cases in the gardeners' section were attractive in both make and furnishing. The first prize was awarded to Mr. Hill, for a square tank having four sides of glass, neatly fitted with rockery and a bit of *Anacharis* and some lively gold fishes; the top contracted upwards, and was surmounted with a small glass-case containing some pretty ferns. Second in this class, Mr. Chadney, for a beautifully furnished fern-case containing several of the choicest varieties of *Scolopendrium*, *Cyrtomium falcatum*, *Asplenium fontanum*, *Adiantum formosum*, and other good things. In a class for "practical" people, Mr. Tarrant had first place, but his case was a poor one. A very nice one in the class for amateurs came from Mr. Dowsett, and took a first place. There were some pretty groups of window plants, mostly well grown, comprising the usual subjects. Messrs. F. and A. Smith, of Dulwich Nurseries, assisted by exhibiting some splendid balsams and a group of *Lilium auratum*. The judges were Messrs. G. Wollett, A. Smith, and S. Hibberd.

Wealth does not always improve us. A man as he gets to be worth more may become worth-less.

The best service that we can render to the world is to mend ourselves; if each mends one, all will be mended.

ROSES AND ROSES.—No. VI.

The last said about roses in this series prepared my friends to anticipate the death of my lot, and O. P. Q. ventured to suggest that ere the summer was half gone I should bitterly repent the deed of April 6th. You will remember that on the date named all our roses were lifted, and within a few days afterwards were planted again. There was a good reason for doing it, besides the one stated at page 146; for not only were they cut about by the winter, but there was great need for other purposes of two borders they occupied. So they were all lifted on the 6th of April, the ground was well dug and manured, and they were planted again about the 10th. During the dry east wind that followed soon after, several standards perished and made unseemly gaps; the proportion to the whole of those lost through being moved so late being full one-tenth: but those that survived have grown and flowered as well as roses were ever known to do in Stoke Newington, and as they were a month later than the average of roses in the same district, we were smothered with flowers when all the rest were gone. O. P. Q. gave me a call a fortnight ago, and the result was that he opened his eyes; upon my word, I began to speculate if he would shut them again. He has been budding a great many briars this season, and has set his heart on standards with a vengeance. Like many other very wise people, he tries hard to ignore my own-root theory, and vows that he followed "Rose Book" last autumn, put in about a thousand cuttings, and has now only three wretched plants to pay him for his trouble. One of the particular reasons for his staring was, I had planted between the standards a lot of own-root plants that were like weeds to begin with. They had been growing on one of our pieces of ground away from house, in a nursery bed, two seasons, all as thick as plums in a pudding, and had never been pruned. After the standards were planted we inserted these dwarfs between, and when they were cut back rather close, there was really nothing to look at, and to have boasted of own roots just then would have been folly. O. P. Q. thought the own roots were a myth, and that the standards would all die. But when he came the other day he found the standards in splendid condition, smothered with flowers, full of fine growth, and the leaves gigantic. He did not even notice the few gaps caused by the deaths that followed the 6th of April movement, so nearly were they obliterated by the free growth of the most proximate to them. But the little bushes at their feet making fat shoots and large leaves, and with plenty of flowers amongst them, chiefly caused the eyes of O. P. Q. to dilate beyond their usual size, and he says, if he could only succeed in striking them, he would grow nothing else, and would be sure of attaining to the highest distinction as an exhibitor. Let him follow the "Rose Book," and he may have acres of own roots if he wants them; and now is the season for all novices to try their hands at striking roses. You will always find a great difficulty as to the appliances in gardens for this sort of work; but at the same time you are sure to find old boxes, frames, spare lights, and perhaps old window sashes that could be turned into lights,—everything in fact except a little zeal and perseverance. When these things are found, a new trouble arises as to the source of bottom heat, and you have no course left then but to argue against artificial heat as unnecessary, and in favour of sun heat as all-sufficient. Any old frame will convert the soil it covers into a hotbed now if the lights are put on and shut close, and that is all we want for striking rose cuttings. The best place for the job is an old hotbed, for the sake of the elevation above the level; but any bank or mound in the full sun will do just as well to suck up the heat and retain it. No kind of stuff answers so well for striking rose cuttings as cocoa-nut fibre, sharp grit, and loam in equal quantities, well mixed up together, and spread four inches deep. The cuttings may be taken at this time of year from any part of the young wood, even fat shoots as thick as the middle finger will root if cut into lengths of three or four joints each. But I prefer before all other sorts of cuttings such as may now be obtained from the wiry twigs that have flowered. You will find your trees covered with these twigs, with it may be fruit or dead flowers on the top, and you may cut them three or four inches long, and make a nice plant of every one, and leave untouched the stout growth that comes from lower buds to make wood for late flowering, and for the improvement of the trees. Moreover, these twigs are of little use, and will have to be pruned out in the spring, and then no art of man can make plants of them. It is enough perhaps to direct attention to this business; there will be no difficulty in the performance of it by those who mean success. My system of striking from eyes is far better than from cuttings, and now is the time for that method also. But I must refer to the "Rose Book" for the *modus*, for too many other matters press upon us just now.

And one of these other matters is to say that O. P. Q. exhibited and won nothing. He trusted to his standards with big heads, and he would not disbud. All the inferior roses at exhibitions are produced in the same way in gardens where the cultivator has not the courage to remove two-thirds of all his buds, and where generally

the brier system is so stubbornly established that one might as well hope to move St. Paul's Cathedral by persuasion as affect this fashion by arguments. For the exhibitor briars are invaluable, for by budding the best varieties every year on young thin-stemmed briars, the finest flowers obtainable by any process may be had. But the system must be followed from year to year; there must always be young briars and newly-formed heads in progress if exhibition flowers are required. But for the embellishment of the garden, own-root bushes, and own roots pegged down, are to my thinking so superior in beauty to the best of brier roses that I wonder how these last keep their ground at all. Somebody must be wrong. Perhaps, after all, a lot of things like mops, with some fine flowers stuck about them, are more handsome than great beds or compartments clothed with a groundwork of green leaves, over-arched and sprinkled with roses in a kind of refined *negligée* style, a sort of billowy mass of foliage and flowers. Everybody, too, can bud a brier, but only a few can strike cuttings or eyes; and so the briars win by their almost spontaneous production, as well as by the superior beauty of the quite artificial and falsely-constructed tree, consisting of a naked rod with a round head at the top, and the disposition of the flowers such that only about one-third of all that are in perfection can be seen at the same time. Somebody must be wrong, for everywhere the briars are there, and the own roots nowhere. In ten thousand small gardens you shall find consumptive standards with heads not larger than the heads of their owners, and producing a few wretched flowers such as might be made in Berlin wool at ten a penny; but to be good imitations of the roses ought to be torn and trodden after being twisted and twirled into the mimicry of roses. Sometimes we see a bed filled with such, twenty or thirty trees perhaps, where there is proper room for only a dozen. At other times they are planted on grass turf, with no openings of any kind to minister of air and water to their roots; and perhaps the grass is well rolled and the stems are now and then grazed by the edge of the roller, and a strip of bark peeled off. This arrangement secures a good hard pavement for the roots, shuts out rain and sun from the feeding fibres, and a sickly growth and ten-a-penny trodden-on Berlin-wool apologies are the products of these concreted victims, which are usually considered to beautify a lawn considerably. At other times pin-cushion beds are made, and we see the mops rise out of hoops of bedding plants, and the case is better; but it must be a curious taste that can find delight in the flowers of a delicately tinted rose while there is a blaze of scarlet on the ground beneath it, to distract the eye and falsify the more delicate colour. A nice sweep of grass, green as emerald, with here and there a Deodar or a Lawsonian cypress, or a Picea, appears to me a much more enjoyable place, and in far better taste than a lawn dotted with standard roses of the customary rigid type, be they the best examples of such roses ever seen in this world or any other. I like to walk across a lawn like that, to see a bed of roses that I can look down upon while I talk with some good friend; and I don't mind if somewhere on the grass there be a great weeping Ayrshire or a huge Blairii, No. 1, with a head half wild, like an old thorn. But I suppose I'm wrong in all this, for the majority are against me; and in small gardens standard roses on grass-plots are such extremely proper things that for all I know I may be ruining the Magazine by the heresy of uttering a doubt about their propriety, so I shall say no more about it, but for a few moments have a look at what I've got, and what I hope for.

I shall begin this business by calling attention to a rose which has given me very much pleasure, and has not yet had its due in any paper of my writing. Good whites are scarce, and here is one that stands alone for beauty; and to make amends for all former neglect of it, I put the name in black letter. It is—

Madame Freeman,

sometimes entered in catalogues as "Madame Freesman," which perhaps is most correct; but it cannot be missed under either name, and it will never be forgotten where it has been done well, and has shown plenty of its large, round, snow-white flowers. To be sure, it is not always snow-white, but sometimes creamy all over, and sometimes creamy only in the centre; but it is always as good a rose of its colour as any in the garden, and nine times out of ten, in the largest collection, it is the best white known. Madame Alfred de Rougemont, with its beautiful centre; the floriferous Louise Darzens, always pure white, and intermediate between a noisette and a perpetual; and Baronne de Maynard, imbricated in form, and white as the old White Bath, with Madame Gustave Bonnet,—are all desirable members of a too limited class, and valuable to bring out the high-coloured sorts, as well as for their intrinsic beauty. Madame Vidot I shall hope to give up in favour of Madame Hoste and Miss Ingram; but it is early to talk of that yet. One of Madame Vidot's great faults is weakness of growth, and it is one of the most difficult to obtain on its own roots. Anna Alexieff I care little for now, though for several years it was first favourite. It is a garden rose, giving as many flowers as

those two particularly free-blooming kinds, Sir Joseph Paxton and Admiral Nelson; Baronne Prevost we must yet keep. Comte de Nanteuil is fine; John Hopper grand, though flattish; Madame Boll superbly showy on account of its richly shaded centre, but flat, and the growth too stiff and broom-like. William Griffiths has been fine this season, the form perfect. Souvenir de la Reine d'Angleterre might be dispensed with, except by such as care for size only; but La Duchesse de Morny, Princess Mary of Cambridge, Comtesse Chahillant, Madame Cambacérés, Glory de Vitry, Victor Verdier, and Josephine Beauharnais are amongst the very pink and prime of rose-coloured roses.

In the strong-coloured classes, our old friend Jules Margottin has been as good as ever, perhaps better than ever, keeping his own amid a host of rivals for his well-earned fame. I must have seen hundreds of tall standards of Jules in my travels this season, in cottage gardens in various parts of the country. Madame Damage too, so liberal of flower, with colour and form so good, must be in the select list, and, like Jules and the General, it is one of the best to strike currant-tree fashion in September and October, in frames or open ground. Beauty of Waltham, Bernard Palissy, François Lacharme, Charles Lefebvre, Baron A. de Rothschild, Xavier Olibo, Alfred Colomb, Lord Macaulay, Madame C. Craplet, Madame Julie Daran, Jean Rosenkrantz, Maréchal Vaillant, Sénateur Vaisse, Vicomte Vigier, and General Jacqueminot, are all in the front rank of reds and crimsons; and those who value roses at more than market prices,—who value them for their beauty, their fragrance, and the real amateur enthusiasm they enkindle in respect of their differences, resemblances, and several special qualities,—will be busy now in striking cuttings of all these, with a view to make chrysanthemum stakes of all their standards, except such as are truly picturesque trees, against which I have nothing to say, for we can all agree in admiration of a thing of beauty.

There are now some fine dark roses with which, till lately, we were not well supplied. I have that gaunt brute William Lobb still; it makes shoots every year about seven feet long, and these flower their full length. Mr. Prior might have been content with such a monster for a "blue rose," instead of conjuring up in his vivid imagination the chimera that so startled us. William Lobb is a blue moss-rose, worth a distinguished place in a bonfire, and I should forget it except that I have it at first-hand, and see it at second-hand in every batch of new roses. Whenever I see announced a violet or purple rose, I expect to see William Lobb again, with or without a mossy calyx. But we have some good dark roses, all more or less shy, but much to be valued for the fine relief they afford to the pink, yellow, and crimson flowers. Prince Camille de Rohan is the type of a class that needs enlarging; it is one of the grandest roses out. Alfred de Rougemont, Eugène Verdier, Souvenir de William Wood, Souvenir de Comte Cavour, Pierre Notting, Baronne Pelletan de Kinkel, and Souvenir de Dr. Jamain, are splendid, and even Louis XIV. is worth having in gardens where there is room for half-a-dozen plants that amongst them will afford only half-a-dozen flowers. If we had never seen the General till it was shown by Mr. Cranston at Birmingham this year, we should class it with the darkest, and suggest the possibility that a veritable black rose had been produced at last. But the General is good, whether bright or dark, whether in its average camellia-like form, when half disposed to show an eye, or as round as a globe, as big as the biggest pugilist fist, and nearly as black as ink, as Mr. Cranston showed it. A bad rose for the trade, though, for the merest beginner in propagating could multiply it *ad infinitum*, either by cuttings now or at the end of September. The trade don't like varieties that are easily multiplied, and no blame to them, for the best display possible at a nursery is a display of customers. S. H.

BEDDING GERANIUMS.—No. XLIII.

Name the best scarlet bedder offhand? It cannot be done; and if we had a council now of the best bedding men in the land, they would differ to an extent probably of a dozen varieties, all of these being supported by a fair show of votes. Who votes for Trentham Scarlet (*alias* Crystal Palace)? who for Cybister? how many for Stella? Hold up hands for Attraction, Firebrand, Hibberd's Pet, Lady Cowper, Confederate, Little David! It's no use; I can't count; you are all wrangling. Give it up; let every one stick to the sorts he likes best for his own particular taste and country. I think it very likely we shall perform a grand *auto da fé* in a few weeks' time in solemnly consigning a great lot to the muck-pit. It will be an "act of faith" of a twofold kind: we shall make room to winter better things than we throw away, and shall effect that purgation we have so long desired. When the deed is done, or thoroughly determined on, I think it will be proper to make a report. For the present I imagine that we shall sacrifice Compactum, Rigby's Queen, Tom Thumb, Crystal Palace, British Flag, Blackfoot, The Old Huntsman, Cedo Nulli, Judy Superb, Magnum

Bonum, and some hundred or so more, and the sweep will be sure to include some of very recent introduction. It is certain that winter must convert many of these into muck; for our own seedlings and first-class things from elsewhere multiply so fast, that, to keep the collection intact, we should soon be compelled to rent the Crystal Palace, and perhaps a few of the big houses at Kew, which would necessitate a lot of tedious negotiations. But, again, which is the best scarlet for bedding? I must plainly say that I have not yet done with Trentham as a bedder, though when it is brought to an exhibition I despise it, and ask, rather unkindly, Who would labour with such a plant for a specimen? So, too, I have not done with Attraction (*alias* Perfection, Mountfordii, &c.), nor with Little David. Those who know them and are used to them cannot be blamed if they stick to them; but my choice now for a scarlet for next year, a very reliable splendid scarlet for beds only, is *Cybister*, which every body possesses, and is too well known to need a word of description. Next to *Cybister* I place *Hibberd's Pet*, though a few years ago I felt inclined to sweep it out; but, strange to say, it has been the most striking in all our lot this year, and some dozen or more geraniums' friends have been extra loud in their praise of its distinctiveness, its abundance of brilliant bloom, and its neat habit. I lately discovered a big house full of it in a nursery, and I asked if there was any particular reason for so many, and the sufficient answer was given, "One of the best to sell; it is so distinct and good." There are certain peculiarities in all the popular scarlets that more or less place them in an inferior position to these two. *Stella* is grand, but rather heavy; *Tom Thumb*, bright but flimsy; *Reidii* is bright, but shy; *Queen* is coarse; *Compactum*, too strong, too leggy, and the flowers are microscopic and a bad colour; *Firebrand* is good, but *Cybister* beats it, except where a very dwarf grower is wanted; *Lady Cowper* is not good everywhere; *Little David* is a very seedy and flimsy thing, though in its first flowering fine. Yes, we must have *Cybister* and *Hibberd's Pet* first; next, for the sake of a change of colour, and a better quality of flower than the two foregoing, Smith's *Excellent* and Turner's *Herald of Spring*. Now we may add *Stella*, and go on fast, because there are heaps of good scarlets. *Baron Ricasoli*, *Black Dwarf*, *Garibaldi*, *Attraction*, and *Scarlet Gem* may be added, and there the wise man will stop if bedding is the only business he wants scarlets for, and he prefers selecting to collecting. I know that some very worthy men cling to the notion that the large flowering varieties, such as *Dr. Lindley*, *Roi d'Italie*, *Beauté de Massifs*, and others of the kind, are fine for bedding; but it is a mistake. We have all these kinds planted out, and the more ignoble kinds beat them so completely that there is not even ground for an argument on the subject. *Dr. Lindley* is one of the grandest possible in a pot, but in a bed becomes a cabbage. So of many others. Then, in such wintry weather as we had in June and July, 1867, the large flowers are the first to bleach and curl, and change from scarlet to slate colour, and at last go out of bloom altogether, and make timber instead for the rest of the season.

Let us now glance at the new ones. I begin with the one which I think should lead, *Lady Constance Grosvenor*, a nosegay remarkable for compactness, brightness, and true nobleness of character. A strange thing to say of a nosegay too, that it is beautiful without flowers, and is almost the neatest and prettiest zoned leaf in existence, and just the thing for raisers of tricolors to breed from! But add the flowers, and they surpass those of *Cybister*, I think. Take the plant all in all, and it is the one above all others most deserving to be called the queen of the nosegays, and it must be one of the greatest favourites for bedding for many years to come. *International* must stand next, but it is less profuse of flowers than *Lady Constance Grosvenor*, and tries to make amends by extra breadth of petal and the finest tone of crimson scarlet hitherto produced, even amongst the Continental nosegays, which are somewhat rich in this respect. *Rebecca* stands the cold, the rain, the sun well, and is to be valued for its fine distinct colour. This is scarcely new, yet very few have tried it fairly yet, perhaps because Mr. William Paul let loose such a flood that people were afraid of being swamped by them. But you may buy it and cut it up with the greatest certainty of earning salt. There is a batch of odd varieties looked out at this moment as worthy to be recommended for any purpose to which scarlets may be put. Some are old, some are new, very few of them are well known. *Omega* (F. & A. S.), a beautiful form and good colour. *Lady Rokeby*, not a brilliant scarlet, but good and making a huge truss; fine. *M. Galland*, a charming variety in form and style, and blooms profusely. *St. George*, a very curious shade of colour like newly-drawn blood; a rather spare nosegay. *General Lee* (F. A. S.), fine form, cerise-red. *Magnet* (F. A. S.), the flower will please those who like *Roi d'Italie*: it is no favourite of mine, for the petals do not overlap. *President Johnson* (F. A. S.) is a very distinct and fine variety for pots or beds, the leaves are darkly zoned, habit of growth robust, flowers finely formed, colour rich puce rose. *Walham Seedling*, rather too strong in growth, superb purplish crimson. *Rival Nosegay* is quite an old friend, unsurpassable in its way amongst the new ones; every collector and

selector should have it. Glowworm makes a good odd bed; it is not free enough to work into a geometric scheme, or at least not to be hastily trusted, but it is the best of the class of shaded flowers and puts *Magenta Nosegay* out of countenance.

Now let us have another look. In a batch from Mr. Thorpe, of Leicester, I find one which has the brightest coloured scarlet in the garden; the leaf is a dull green, scarcely zoned, and the flowers are loose. It has been conspicuous all the season for its intensity and brightness of colour. Another beauty is *Chater's No. 334*, a most beautiful white-eyed scarlet, with superbly zoned leaves. This beats *Bull's Beauty*, and probably surpasses in finish and splendour all known varieties of the white-eyed class in brightness and finish. Lastly, *Sir Fitzroy Kelly* bears comparison with any broad-petalled circular flower we have. Every lover of finely-formed flowers must have it.

In the Christine section, *Christine* is the exact parallel of *Tom Thumb*, dwarf, free, showy; full of faults. *Roseum nanum* is far before it in style, and *Christine Nosegay*, *Pink Stella*, and *Wiltshire Lass*, threaten it with extinction. *Madame Barre* is a fair-weather flower, hence it is only within the past fortnight it has made a respectable appearance. *Lady Cullum*, *Beaton's Premier*, *Helen Lindsay*, *Pink Globe*, and *Beaton's Perfection*, are now useless; the march of improvement has overtaken and displaced them. *Pink Beauty*, good; *Rose Rendaller*, grand, if allowed to get up above the dwarfier kinds, and show its pure pale pink trusses. *Minnie* and *Mrs. Whitty* will do for the present. Better than any of the rivals of Christine is *Chater's N 10*, a rather stronger flower than Christine, with very large bonnet-shaped flowers, showing a richer tone of colour than Christine; stouter in substance, and little inclined to make seeds. The best novelty of the season in this class is *Cliveden Rose*, one of Turner's lot; it puts *Amy Hogg* aside; it is glorious in colour, bears bad weather well, and gives twice as many trusses as any other variety of its own shade or colour. Put down *Countess of Sefton* and *Groom's Miss Martin* as eminently desirable, whether for beds or pots. *Miss Martin* is, in its class (a sort of salmon pink), the proper companion to *Dr. Lindley*, of the scarlets, the most perfect in form in the whole range of varieties.

There is no white in cultivation to equal *White Perfection*. It is refined in form, scarcely given to colouring, flowers abundantly, and is as good for exhibition as a bed. *Groom's Floribunda nana alba* (a bad name) is a capital dwarf grower, and will admirably take the place of *White Perfection*, where that would be too robust. We shall destroy *Hendersonii*, *Galanthiflora*, *Skeltoni*, *White Tom Thumb*, and a few others; but have no idea of sweeping out *Madame Vaucher*, *Madlle: Marie Vincent*, *Virgo Marie*, *Etoile de Venice*, or *Snowball*. Bedding people should always regard *Madame Vaucher*, and her child *Snowball*, as *Blush coloured*, and work up to them and from them accordingly, for if there is enough sun to make them flower, there is enough also to colour them deeply. *King of Whites* is first-rate for small work and edges.

We have some superb painted varieties planted out, and one of the most remarkable is *Vestal* (F. A. S.), which flowers as well in the full sun, and during bad weather out of doors, as under glass. It is exquisitely beautiful, circular, and slightly cupped, the rim of the cup pure white, the base of it brilliant carmine, laid on in a sharp circular disk: call it a white flower, with a large circular carmine eye. F. and A. Smith's *Siren* is better than *Souvenir de l'Isère*. *Madame Rougler* makes a pretty bed or line; it has a carmine centre shading to blush edge. *Eugénie Mezard* is still in the front rank, whether for delicate painting in the shade, or clear salmon flesh in the full sun. *Madame Werle* is good for all weathers, though so delicate-looking; and *Madame Brandet* (F. A. S.) deserves a distinguished place for quality and beauty, the flower being one of the best in form, the edge pure white, the centre brilliant carmine. S. H.

THE PLUNGING SYSTEM.

On the principle of *Audi alteram partem*, I was not only bound but glad to give insertion to a paper on this subject from the pen of Mr. J. E. Saunders, who came here expressly to see what was meant by the "plunging system," and went away with the conviction, fully stated on the 20th of April last, that this system is specially adapted for producing a continuous and brilliant display in every season throughout the year, but that it is extravagantly costly. So many other subjects have demanded attention since then, and my engagements away from home have been so numerous and have consumed so much time, that I have been quite unable till now to say a word on the subject. *Audi alteram partem*, then, for me as for him. I at least must know something about it, for the system as followed here is the growth of ten years, and we could no more do without it now than we could without roses and potatoes, and mint for peas, and funnel for mackerel. The front court, where the plunging system is carried on, is so overlung with large trees that to plant flowers in the borders would be to doom them

to death, or near it; the plunging system is a necessity as the case stands, else we must be content with evergreens only, with perhaps an undergrowth of woody nightshade, periwinkle, and ivy, whereas we do have a display that is at all times delightful, and sometimes rather startling in its beauty. At the present time our colouring is quiet, for we worked up our flowers to such a pitch that I was glad, being perpetually amongst flowers abroad and at home, to make a change and have a grouping of leaves only. Our climax for the season was attained when the geraniums were in the full splendour of their first bloom, and *Eriogonum Fraseri* was brought forward and placed in the back row of the border, mixing its fine yellow flowers with the geraniums, and the moment the *Eriogonum* began to decline we cleared all out and brought forward our leaves.

There are several interesting points demonstrated by our practice of this system. First and foremost, in a court, small of its kind, but I flatter myself somewhat tasteful in its design and furnishing, where big trees overshadow the scene, flowers may be employed to an extent impossible by any other means. We bring them forward when they are at their best, there is sun enough to keep them so for four or five weeks, and then we remove them and supply their places with others. There is thus a succession of displays lasting the whole year round without a break, for our borders are never unoccupied, and the stuff we use is always beautiful. Not only so, but this sort of display completely outshines in splendour the very best that can be done by ordinary bedding. There is no waiting for effect; in the month of May, when bedding has not yet commenced, our flowers are brighter and richer than they are elsewhere in July, when the bedding-plants have just got to rights; for we turn them out of the houses, pack them close together, and arrange them for effect, knowing that if they get a little dirty and leggy through close packing, we can soon restore them when they go back to the reserve ground, and there are of course plenty of others to take their places when needful. I therefore claim for my system that it will give every imaginable variety of colour to a spot where by any other means colour would be impossible, but it gives more colour, more variety of colour, and colour at a time when it would be otherwise unattainable. It is *par excellence* the system for the approach, and I beg our readers to understand I have never advocated its adoption for the parterre; it would need the purse of Cræsus to carry it out on a large scale, and if so carried out would be a foolish extravagance such as I would be no advocate for; rather I would say that in gardening, as in all other pursuits, a man should keep his hobby-horses in subjection, and never suffer them to ride over him, nor should he, if able to afford it, indulge in gratifying the lust of the eye unreasonably. For an experimental garden situated as ours is, and so limited in extent, it is the most proper thing possible, for it turns to account all the many subjects we cultivate, displays their beauties, demonstrates their uses, and makes the spot assigned to the experiment delightful at all seasons.

Secondly, and this is a matter of great interest, our system proves that judicious mixtures are far more enjoyable than self-masses of colours, in places where the display is to be seen by the same persons day by day for any length of time together. Hundreds, I might say thousands, of persons are familiar with the features of our plunging display,—and if I go wrong in a word, I can be corrected, and you know that *audi alteram partem* is a part of my religion. Talking of religion, I can't help saying that it is a bad rule that requires a congregation to keep silence while the minister preaches, or at least forbids remarks and criticisms at the close of the sermon. I should often like to get up and say, "Reverend So-and-so, you have laboured hard to expound your views on a subject which no human being can understand. Next time you preach, I want you to prove to me how necessary it is I should speak the truth, pay my debts, love my wife, abandon hatreds, pray for my enemies, and do all things, even in eating and drinking, for the glory of God." But my lips are sealed, or, at all events, if I followed the impulse that is often strong upon me, I should appear before a magistrate every Monday morning on a charge of brawling. But to resume the thread—*pardonnez-moi*—if I go wrong in a word I can be corrected. Now for several years we have not had one single display arranged according to the rules which govern the bedding system. For example, the centre circular bed has never been a mass of scarlet or yellow, or any other colour; the borders have never been furnished with distinct, hard, sharp lines of colours, such as a line of red, a line of white, a line of yellow, a line of blue, &c., &c. Our most satisfactory effects always are mixtures. It is interesting, too, that the very best mixtures we have ever had are mixtures of geraniums. Such a mixture is most beautiful. I could write for a week in praise of it, if only our copious English tongue would afford a supply of suitable adjectives. Take the centre bed, for example: we fill it with plants of all colours, arranged according to heights, so as to construct a regular pyramid, the tallest plants in the centre, and thence smaller and smaller to the outside. The result is a mixture of scarlet, purple, pink, rose, white, and the intermediate shades. To be sure, the plants we use are mostly seedlings; and in their first strong bloom, when averaging three

to five feet high, they beat all that can be grown from cuttings; yet the same effects can be wrought out from cuttings of named varieties, and our advantage in that respect is a mere accident. Amateurs must allow us to beat them in some things; we can't help it—it's our trade; but I make amends, I hope, by telling them everything. What more can I do? So, again, in respect of the borders, we repeat the same colours at regular distances, but we always fill in with mixtures, and have bits of green and gray at regular intervals amongst the most brilliant flowers. I am afraid to propose the planting of beds with mixtures of geraniums; but I am inclined to think it might be done, for we only need to select half-a-dozen sorts for a bed—say, Crystal Palace Scarlet, Christine, Madame Vaucher, H. W. Longfellow, Amy Hogg, and Countess of Sefton—and plant them alternately all through. These would keep pretty much to the same height; and I cannot but anticipate the effect would be gratifying to a cultivated eye. At all events, our mixtures—I say "our" and "we," because I don't wish to be everybody in a matter which other and able and faithful hands take part in—our mixtures, I say, are most pleasing; and this brings me to another of the lessons of the plunging system, which will make occasion to commence a new paragraph.

Another lesson we have learnt is, that everything capable of being plunged out of doors, and possessing intrinsic beauty, may be turned to account. Palms, Ferns, even Equisetums, and grasses are used here. Twice this year we have made the principal part of the display consist of ferns, with bits of colour here and there to light them up. The system, in fact, is without limit practically, for whatever you can grow in a pot may be carried to the border or bed, and be plunged in the place best fitted for it. This leads the way to the next paragraph, in which there is to be dealt a dreadful blow to our friend Saunders; may he live through it!

The fact that almost anything can be turned to account makes an end of Mr. Saunders's objection that the system is beyond reason costly. Let me give you an example. The display at this moment consists of leaves with a few quiet flowers to light it up. In the centre bed a mass of *Variiegated Epilobium*, the one sent out some years ago by Mr. Salter: it is the *Epilobium parviflorum variegatum* of the books. As a pot plant this is exquisitely beautiful; the plants average 20 to 30 inches high, almost wholly white in leafage, with a few rosy flowers at the summit. They are packed close together, with plants of *Iresene Herbstii* alternating. The *Iresene* forms a dull claret-coloured groundwork. This mass is encircled with *Coleus Verschaffeltii*. The boundary line consists of tufts of all the new *Alternantheras*, with plants of *Mrs. Pollock Geranium* at regular distances. It is a quiet affair, but chaste, rich, and novel. In the long border there is a back line, consisting of plants of the *Epilobium*, tall *Lobelia*s of the *cardinalis* and *fulgens* sections, *Lilium lancifolium*, *L. auratum*, and some other odd things. All these alternate regularly, so that at so many feet distance there is a white-leaved *Epilobium*, a lily, a scarlet or rosy *lobelia*, &c. The next row at this moment consists of geraniums; a fortnight ago it consisted of *Sedum spectabile* (*S. fabarium*), for the sake of its leaves; but it was too cold in colour, and I had geraniums brought up to warm the scheme. The front line of this border consists of *Coleus*, *Iresene*, *Alternanthera*, *Mrs. Pollock*, and a few other tricolor geraniums. The fact is, we had not enough of *Mrs. Pollock* in pots to finish with, and we put in *Yellow Belt*, *Golden Chain*, *Gold Pheasant*, *Luna*, and others. The little border under the windows has a back row of *Tiger lilies*, next in front a few plants of the *Lily of the Nile*, *Calla Ethiopica*, in flower (we flower this well in summer by keeping the pot plants always in an inch depth of water in a hot sunny place, so that if we want it, it is always fit for use), and the rest of the border is filled in with ferns. These last comprise our best specimens of the most showy Britishers, exhibition size, and some of them unique specimens. So far, it will be understood that we do not want the purse of Cræsus, or any other such beast, to pay for our plunging. What do you suppose was the cost of our willow herbs (*Epilobium parviflorum*)? One day in the past spring, I said to George, "Pot so many of that willow herb that grows on the rockery." I should give you the exact number, but at the moment of writing I don't remember it, and the wind is too high for me to carry out the lamp and count them. But suppose it to be a hundred. Well, the cost of potting may be calculated at six shillings for pots (forty-eight's), and some pence to spare. Say three shillings more for time and stuff, and that's all. One penny each is about the actual cost of those lovely plants, for, as to soil, they grow best in the stuff that has been used over and over again, taken from a heap that is kept on purpose for variegated plants. We could take five hundred plants next spring from the same bank, and indeed a lot of it will have to be destroyed, for it is spreading too fast, and is actually killing out some of my seedling conifers that happen to have been planted near it. Please take note of this, friend Saunders. Again, in the spring of this year I noticed that a plant of the lovely *Tanacetum vulgare crispum* had gone very wild, and was running about like a will-o'-the-wisp, so

I said, "Make an end of that as a border plant; it is too vagrant in habit for us, and pot a lot in sixties; we shall be glad of its green leaves." No sooner said than done. They were potted in trash; not the least occasion for fresh compost for it, the heap of old stuff from pots served the purpose, and in due time we had a beautiful lot of plants. As they stood all together in an old brick pit, they had so charming an appearance that I used to steal into the frame ground every morning and have a quiet look at them, always asking myself the question if *Todea superba* (*Leptopteris superba*) could surpass this weed in beauty. We found them very useful. Before they got leggy, as they are now, when in fact they were lusty and lovely like new-born love, still flushed with the smile of innocence, we used them for a margin to a bed of rich colours, and the effect was glorious. Those of our friends who did not know it was only a refined form of tansy were furnished with the botanical name *only*. They might have sneered at the English name; or worse, they might have got a tuft of common tansy, and then have said it was rubbish. I am too used to such things to be off my guard, and I consider it a duty to defend beautiful plants, however cheap and common, from the shadow of detraction. Pardon a moment's digression. I once had a splendid rockery covered with wildings, all of my own gathering from copse and dell. A dear old friend who knew nothing of horticulture used sometimes to join me over a cigar beside that scene. Said he to me, "What is that gigantic woolly-leaved plant with a candelabrum-like stem covered with yellow flowers?" I replied, "That is the common mullein, a British weed." Dear old friend acknowledged the information with a grunt. Presently he asked, "What is that glorious patch of azure blue, looking as if a bit of the blue sky had taken root to bless you?" I replied in the same modest manner, "That is the germander speedwell, a common British weed." Dear old friend acknowledged with another grunt; and presently added, "What a waste of ground to plant such common things!" I at once took him for a type of a certain species of the genus *Homo*, and waited for his next question. "What a splendid mass of yellow you have there!" said he. "What is it?" I replied, "*Lysimachia thyrsoiflora*," with not a word about its being *also* a British weed. "Ah," said he, "that's something like." So I learnt a lesson, and have found by much experience that it was a good lesson. No, no, no, you don't sneer at my British weeds again, any of you, if I can help it. That lovely yellow flower you saw in the spring in the park was *Leontodon taraxacum*,—I can say inwardly and inaudibly, "a British weed," without bringing contempt upon the beauty, or putting to needless question the taste of Ebenezer Elliott, who made a glorious song upon the Dandelion. Time now perhaps for another paragraph.

In the way of cheapness we have another example. In the month of September we shall have a good display, in which *Sedum spectabile*—the *Sedum fabarium* of trade catalogues—will play a conspicuous part. I don't remember how much I paid for the first bit of it; perhaps a shilling. No matter if five times as much. The plant can be propagated from cuttings in spring with the greatest ease, or it may be divided by simply cutting through the crown, and potting pieces with roots. It is as hardy as sin, which frost does not kill, and as good as virtue, which the hottest sun cannot change to vice. Any soil will do, no training wanted—not a single stick; and if you forget it for a week in hot weather, and give it no water, it does not matter—not a sign of distress. Come here, Mr. Saunders, in September, when *Sedum spectabile* is in its prime, and you shall confess that there never was a cheaper spectacle; for we will group it with some other cheap things, and the plunging system shall be vindicated by these hardy, self-propagating, beautiful members of the plunging family, that, like Newfoundland dogs, never ask about the water-rate before they plunge, and do not need a laundry to be carried after them to prevent them taking cold. As for the spring flowers, friend, that you saw, they are not costly. You may make them so if you like. It is our custom to grow every year complete collections of tulips, hyacinths, crocuses, and Nareissi; but you need not do so if you want to plunge in *medias res* into the cocoa-nut bed. We had some cheap hyacinths to help out from Messrs. Low and Co., last autumn, at about fifteen shillings per hundred, and potted them singly in 60-sized pots, and they came in well with specimen bulbs here and there to give character to the mass, and the effect was grand. If you want to know what became of them all, I could now show you a store of as fine bulbs as any that will come into the market this season, saved from the display of last spring; and another store of bulbs wholly raised here, and that have cost I know not how little, for they have been grown in just the same way as shallots, only buried instead of being stuck on the surface; and at so much per rod or rood or acre, measure it as you will,—any way but at so much a piece, for their cost individually must be reckoned in farthings, and at fifty farthings to the shilling (near enough for this guess), a thousand will cost only one pound sterling! Double it, if you like, and you need not be ruined. But if you wish to effect in one blow what it cost me ten years of steady practice to accomplish, with a pre-

ceding ten years of practice other ways to bring about, you may be disappointed. My advice to beginners in plunging has always been, to try it first with some special border near the drawing-room windows, and by degrees to extend the system as circumstances may dictate and require. Rome was not built in a day, they say; nor has our plunging system been perfected in one season, or by any one happy guess. It is the growth of years, and the fruit of many experiences, and I shall be as ready to tell of all my mistakes and failures as to record, as I now do, in a hasty manner, the sum-total of my successes. S. H.

SALADING FOR THE WINTER.

By the time these notes are in the hands of your northern readers, it will be time for them to be thinking about preparing the usual amount of salading for the winter, and I am constrained, with your permission, Mr. Editor, to give those who may require them a few hints upon the subject. But, first, I must not forget those favoured southern readers, or they will be accusing the old man-of-partiality. But, bless you, an old man like me has no partiality for either north or south—they are both the same; in fact, they are, like all other readers of these pages, on an equal footing, as I think of them all in their turn. But this salading is the question now, and how are we to preserve it? Those living northward must lose no time after they have read this article in looking up all their old spare frames, and to clear out their brick pits, and every available space that has a foot of glass for a covering must be brought into use, in which to plant a number of young endive and lettuce plants. All these structures must have some amount of drainage beneath the soil. A quantity of long dry litter trod firmly together will serve the purpose, in the absence of anything better. From eight to ten inches of soil is sufficient, and this must neither be too rich nor too poor. If too rich, it will cause them to grow too quick and succulent, and consequently they will be very tender. If the soil is poor, they will be stunted in growth, and instead of being crisp and tender, they will be leathery and hard. The pits or frames should be filled up with soil to within fifteen inches of the top, and pretty firmly trod before planting.

The plants should be selected from those sown in the early part of the present month, and planted out a foot apart each way in the pits or frames. For a good winter lettuce the *Hardy Hammersmith* or the *Victoria Cabbage* is the best, and the *Mossy Green Curled Endive* is not to be beaten. After planting they should be watered, and, if very bright clear weather sets in, shaded for a few days. No attempt to put on the lights should be made until there are actual signs of frost, or there is likely to be a continuation of wet weather. In the latter case the lights should be used only to carry off the water, to be tilted both back and front to admit a current of air, taking care that the blocks used to give air at the back be considerably larger than those in the front. This will give a sharper angle to the lights, consequently the water will pass off quicker, and then there will be less danger of drip. The lights used for this purpose are generally the most rickety of any on the place; and we should remember that drip is the abomination of winter salading. Providing there are no pits or frames at this time to spare, the plants may be planted on a dry sheltered border, to be hereafter lifted and placed in the frames. When this plan is adopted, great care is required in planting in the pits when the plants are large. In the first place, the plants themselves should be as dry as the season of the year will admit of their being when they are brought in, the soil in which they are planted should be moderately dry, and the plants carefully watered at the roots without wetting the leaves. By adopting and carrying out these precautions, the last plan answers nearly as well as the first, with a little more labour.

The above remarks are also applicable to the case of the southern reader, except that he need not commence operations so soon by a fortnight. He may select his endive plants from the sowing made early this month, but lettuce sown a fortnight later will be forward enough for the south of England. He may also plant out a good number under the foot of a south wall, and in mild winters this often carries the supply on to Christmas. This is an advantage in favour of a southern gardener, as he need not provide such a large number under glass; and this should influence him in not planting too early in the pits, nor using plants very large, or they will get too crowded before they are wanted for use. When the plants begin to touch each other, they prevent a free circulation of air; consequently there is a greater accumulation of damp, which is a dreadful enemy to these succulent subjects. In every case an abundance of air must be given both night and day in mild open weather; the lights to be taken off when it is not actually raining or freezing at night. In open weather the lights should be tilted at the back; frost should be excluded as much as possible, but at the same time they must not be shut up in the dark for more than one or two days at a time. In the above remarks there may appear to some a good many minor details upon a common subject,

but I am convinced, from a long course of years of experience, that they are all essential to the successful keeping of salading through the winter. With this remark the old man will close this short article, and sign himself as usual.

THE MAN WITH THE BLUE APRON.

MESSRS. F. AND A. SMITH'S NURSERY, DULWICH.

The fame of Messrs. Smith's tricolor geraniums having spread far and wide, I felt a strong desire to see them at home, for the threefold purpose of enjoying the sight, making selections for myself, and selections for our readers. I found the nursery as interesting as ever, and regretted time did not permit me to have a good hunt through the pits and houses; but as seeing the tricolors was the principal object of my visit, I hurried past a thousand things that else would have detained me: a few furlongs of hard-wooded plants, the heaths especially glittering with the bright verdure of vigorous health. The balsams I did look at, only to wonder how seed could be got from stock so highly bred; the plants were tremendous in size, and sumptuous in their abundance of large rosette-like flowers of all colours, not the least beautiful being the pure white and striped varieties. We very soon got amongst the tricolors, and I rather wonder now that I got away from them; for a lover of such things might be pardoned for taking up his abode in their midst, and refusing to move on. We began the inspection in the parterre which adjoins the dwelling-house, where the bedding varieties are planted out, and have to bear the brunt of rain and sunshine, cold and heat, and prove themselves by the severest of tests. At the head of the garden is a bed consisting of the variegated *Polemonium ceruleum*, edged with blue Lobelia—a most chaste and quiet bit of colouring. As compared with variegated geraniums, it is less showy; it is one of those pretty things that you may look upon again and again with pleasure, its elegant fern-like leaves being at once peculiar and characteristic. Comparing it with its original green-leaved form, the old "Jacob's ladder" of the cottage garden, one might be justified in suspecting the reality of the relationship, so much is its aspect altered by the bare fact of its variegation. Here is one more good poor man's bedder, a hardy plant of most refined character, which will require pit protection at the utmost, and in dry sheltered places will endure the winter with the same impunity as its thoroughly hardy parent. In other beds are groups of Mrs. Pollock, Italia Unità, Mrs. Barry, Aureum, and other bright-leaved geraniums, in the most perfect health, and beautiful beyond description. The beds are all raised above the level slightly, and are connected with scrolls, in which are planted specimens of all Messrs. Smith's new and splendid varieties. I made notes of a great many, and shall now enumerate and briefly describe such as most particularly attracted my attention.

Aureum, just referred to, is a golden-leaved variety, of the brightest tone of yellow, with trace of a zone. The flowers are clear delicate cerise, produced in abundance. As a bedder it is unique; the leaf bright enough to allow of the removal of the flowers, yet the peculiar tint of the flowers renders this less necessary than in the case of strong scarlets.

Golden Globe, a golden-leaved variety, of compact habit, with beautiful cerise flowers. This is as good for pot culture as for bedding, and first-rate either way.

Crystal Palace Gem, a golden-leaved variety, with the flowers of Lady Middleton. The leaf is superb, being slightly blotched with bright green—that is to say, the disk is irregular and small; the remaining part of the leaf rich sulphur-yellow.

Mrs. Charles Barry is a bronze zonal, superior to Luna; the flowers scarlet, the zone bright and ruddy; habit rather robust, and in a bed most effective.

Pet of the Parterre, a golden-leaved variety; the leaves yellowish green, flowers rich scarlet; one of the best bedders on the ground.

Vandyke, lighter in the zone than Mrs. Barry; pretty, distinct; the flowers rosy salmon. I cannot give this so high a place as the others in the series; it is good for a collection, but not wanted where a few are grown.

Aurora is a gold zonal, with large bold leaf, and most brilliant tones of yellow and red; a most grand and telling kind, whether in a bed or a pot.

Criterion, a bronze zonal; the disk and margin sulphur, the zone rust-red; the leaf round and flat, a "criterion" for judging, and a most brilliantly-coloured variety. The term "rust-red" may suggest an undesirable colour, but it is the only term I can think of as descriptive of the colour, which might perhaps be described as cinnamon washed with red.

Standard is a bronze zonal; the leaf round and flat, a "standard" of form for judging; the leaf has more green in it than that of *Criterion*, and the zone inclines more to chocolate; rich, decided, beautiful.

The Moor is a bronze zonal; sulphur disk and margin, zone rich reddish chocolate; first-rate.

Brunette, a bronze zonal; the disk and edge greenish sulphur, the zone bright russet-red; habit compact, and the leaf a model of form.

Model, a bronze zonal; flat round leaf, disk and edge canary yellow with a tinge of green; the zone a clear red; peculiar and first-rate.

Plutus, a bronze zonal of most remarkable character; the leaf round and flat, or but slightly convex; the disk and edge canary colour, the zone bright rufous-red. This is one of the most brilliant and distinct of the family, worth any money; a bedder, too, and for exhibition capable of the greatest things.

Gladiator, a bronze zonal, and the most brilliant possibly of all known varieties of this section; neat medium habit of growth; the leaf round and nearly flat, the disk and margin sulphur, the zone clear chestnut, just the colour of a chestnut newly removed from the green husk, which is the most beautiful tone of brown known in natural colouring.

Combatant, a bronze zonal; the disk and margin greenish yellow, the zone approximating closely to a carrot-red.

Morning Star, a bronze zonal; disk and margin a lemon-yellow, zone a remarkable shade of cinnamon passing into red.

Coronet, a bronze zonal, remarkably neat in habit; leaf round and flat, a bright green disk, the zone rayed black and red; splendid.

Miss Burdett Coutts, a silver zonal; the disk green, broad whitish edge, zone rayed dark and brilliant carmine. A fine variety of a class at present too limited, and capable, so far as we can at present imagine, of unlimited expansion.

Peri, a silver zonal, in the style of Italia Unità, but brighter; the margin is pure white, the zone brilliant rosy lake. As seen by me on the 1st of August, I give this the first place in its class. In a better season than the present it will no doubt be still more brilliant and pure.

L'Empereur, a gold zonal; the margin broad and bright yellow, the zone brilliant black and vermilion-red; one of the most splendid of its class, and in form of leaf and habit of growth first-rate.

Charles Dickens, a golden zonal; the leaf very flat, a good grower, very constant in colours, margin clear lemon yellow, zone rayed dark and red; sometimes a self zone of the brightest vermilion; a splendid variety.

Alhambra, a gold zonal, in the way of Mrs. Pollock, but surpassing it in habit and colour; the best bedder at present of this group; colouring brilliant.

Sunray, a gold zonal, margin bright yellow, zone rich magenta with shades of black, one of the best of bedders, superb also for pots.

Defiance, a gold zonal, the margin bright yellow, the zone rich carmine, red, and black; the growth admirable; a superb variety.

Eclipse, a gold zonal, the leaves too deeply lobed, the yellow margin bright yellow, the zone brilliant vermilion-red. In colour this has no parallel, but having given a code for judging, I am bound to stick to it, and find fault with the deeply indented leaves.

Impératrice Eugénie, a silver zonal, margin creamy white, zone bright pink and black, the habit neat and compact, in growth almost a miniature; a charming variety for small beds and vases.

Jetty Lacy, a gold zonal of the finest character, the leaf narrowly margined gold yellow, zone intense chestnut, red, and black; habit all that can be desired; a grand exhibition variety. In the open ground this grows well, and is most striking.

Louisa Smith, a gold zonal, leaf margined with clear yellow, which, as in the case of Mrs. Pollock, fades to whitish; zone bright red and black. This is of vigorous habit, and at first sight an inexperienced judge would proclaim it the same as Mrs. Pollock, but when out of doors it is quite distinct, and a better grower; one of the best, in fact, in this glorious class.

Queen of the Fairies, a silver zonal, margin white changing to cream, with a soft tinge of blush; zone deep rosy lake and black; most beautiful, chaste, delicate, unique.

Souvenir de Sir Joseph Paxton, a gold zonal, the margin very narrow, but very bright gold yellow, the zone deep crimson, red, and black; as the leaves acquire age they change to a soft rosy zone and paler yellow; a good plant, shows a variety of colours, all good.

These are but a few selected from the many splendid varieties in Messrs. Smith's magnificent collection. Instead of advising people to go and see them, I think I ought to advise them to keep away, unless they have perfect control of themselves; for they might otherwise be seized with an impulse to make a bid for the whole lot, as I did, and it was only by the reflection that the sum-total might interfere with domestic finance that I escaped, still the possessor of those thousands that it would require to make a clean sweep. Those of our readers who can command themselves under the fiercest of temptations may go, but no others.

S. H.

TRANSPLANTING IN HOT WEATHER.

For many years past we have always been quite successful in setting out strawberry and other plants in hot weather, and during seasons of drought, by dipping the roots in a small vessel of soft mud as soon as they were lifted from the ground, and then pouring water into the hole so as to form a puddle, when the roots were slightly covered, and then filling the hole with pulverized earth, so as to leave a dry mellow surface. Covering the earth with an inch of fine manure added to success and a stronger growth.

We observe in a late number of the *Horticulturist* a communication from C. J. May, of Warsaw, Ill., describing his success with a modification or improvement of this mode of planting. He lifts his plants from the soil, shakes the earth from the roots, and immediately places them in a vessel of water. In this way they are carried to the place of planting, the roots spread out in the hole, and immediately enough water poured in to float the roots out at full length. Fine mellow earth is immediately drawn or sprinkled into the hole, taking care that no water comes to the surface to form a crust by baking. This is the whole operation, the earth not being packed, but allowed to settle by its weight only. The most valuable and essential part is the perfect encasing of every root and fibre with fine earth, effected by the agency of the water. It is essential that the ground previously be deeply and finely mellowed. The following results from the use of this mode of transplanting are given in the communication above referred to:—"I have been experimenting with strawberry plants, and find that they can be transplanted during the hot months of June, July, and August, equally as safely and as well as in spring or fall. From July 1st to August 31st we have had unusually hot and dry weather, even for the valley of the Mississippi, yet every week I have planted strawberry plants, from twenty to thirty each time. Some of the plants—in fact, nearly all—were planted when the soil was as dry as it possibly could be; not a particle of moisture in the surface soil; and after some of these plantings not a drop of rain fell for four or five weeks; yet they withstood the burning sun without protection, without watering, or checking their growth in the least. I have not lost a single plant up to this time, and those planted first have thrown out runners, covering nearly as large a space as the runners of plants set in the spring in the usual way." He also tried the following experiment with evergreens:—"Out of thirty-four large evergreens, I planted thirty in this way and four without water. The thirty are all alive, and have made a good growth; two out of the four are dead, the remaining two made no growth, not even starting to grow. Several persons who had trees out of the same lot have lost nearly all, so have they their fruit trees, while none of mine have failed to make a large growth."

The same article contains the following extract from another writer:—"In July last, during the hottest weather of the season, I set out two thousand strawberry plants in the same way as mentioned in your letter, with this difference, that in place of drawing dirt into the water, I dropped it gradually around the plant until sufficiently thickened up to hold it firm; then cover with an inch of dry dirt. A drought prevailed at the time of setting, and continued five or five or six weeks, yet they withstood the scorching sun without protection or watering, or in the least checking their growth. I have set out many hundred plants, but none looked so well. I take up a plant, shake the dirt from its roots, and set it out on a hot scorching day, in the full glare of the sun, without wilting or in the least checking its growth. Few are prepared to believe this, but nevertheless it can be done, with the leaves remaining as erect as when standing in their original bed. This plan, to those largely engaged in transplanting, will prove very valuable; no other will compare with it."—*The Cultivator (America)*.

Calendar.

WORK FOR WEEK COMMENCING AUGUST 17.

Kitchen Garden and Frame Ground.

BROCCOLI planted now need not be more than 15 inches apart. They will be rather crowded when spring comes, but they will pass through the winter much more safely than if planted farther apart.

CABBAGE.—If the ground is not already overstocked, sow a few pieces of *Rosette Colewort*, *Enfield Market*, *Red Dutch*, and *Champion*.

CAULIFLOWERS to be sown on raised beds of fine rich earth; when they have their first rough leaves, to be taken up and potted in thumb-pots, in good fuchsia compost, and the pots plunged in a bed of coal-ashes. As soon as the pots are full of roots to be shifted to 60's, and in these to be wintered in frames, the pots plunged to the rim to prevent frost touching their roots. This may seem a dandified way of treating cauliflowers; we can only say that experience has taught us that it pays better in the end than any other method for a crop to plant out early in the spring.

CELERY is growing freely, in consequence of the abundant rains. Where the plants are forming stools instead of distinct hearts, it is advisable to remove with a knife the outside suckers, so as to reduce the growth, if possible, to one set of stems. This stooling is the result of free growth after the plant has received a check. It is so far objectionable that stooled roots are only fit for the cook; they are unfit for the table.

ENDIVE.—A last sowing may be made to stand the winter. All the sorts are good, but *Green Curled*, *Imperial Batavian*, and *Moss Curled* are the best.

LETTUCE may still be sown, and plantations may be made from seed-beds sown last month.

ONIONS ought now to be ripening off; and if the weather continues dry, no doubt they will ripen well. Where they appear gross, and not inclined to ripen, sweep them over with a long stick or rake-handle, so as to lay down the tops. Generally speaking they fall over of themselves, and the bulbs ripen without assistance. Sow for winter and spring supplies. The most hardy kinds are *Brown Globe*, *Deptford*, *White Lisbon*, *Globe Tripol* and *Strasbourg*.

POTATOES to be taken up as soon as ripe. Let them be well dried in the sun, and stored away at once. Never pit them damp, but on the other hand never keep them lying about on the ground exposed to daylight beyond a reasonable time.

SPINACH for winter may still be sown, and the best sort is the *Prickly*. In some places spinach sown in the middle of September goes through the winter well; but on cold soils, and in all eastern and northern districts, the winter spinach should be sown before the 20th of August.

TOMATOES.—Let these ripen on the vines if possible, and if any fruits are shaded by leaves, remove the leaves to admit the sun to them. In case of bad weather, and no chance of the fruit ripening out of doors, cut off the branches with the fruit attached, and lay them on a top shelf in a sunny greenhouse, and the fruit will ripen perfectly. If no sunny greenhouse, a window in a warm kitchen will do.

WINTER GREENS lately planted are now doing well. Breadths that were planted early and close now require every other plant to be removed, and there will be room for this now that summer crops are being cleared off. For every kind of green to be used between this time and Christmas manure liberally, but for those to stand till spring do not manure at all.

CUCUMBERS for winter fruiting must be reared at once, and cuttings are preferable to seed, as the plants have a shorter habit, and are more fruitful. Take very small cuttings from the ends of newly-made shoots, pot them singly in small 60's, and shut up over a gentle bottom-heat. As we are not now using dung-beat, we shall put a small frame over a heap of grass-mowings mixed with dry litter, which will afford enough heat to start them, and keep them going till new beds are made up. But beware of grass-mowings alone, unless cooking, and not growing, is the object. One-half dry litter, and the other half mowings shaken over, will produce a steady lasting heat, of great value at this time of year, when it is not generally convenient or desirable to have dung wheeled in.

MUCK-PIT.—There will for several weeks be vast accumulations of rubbish by removal of pea, bean, and potato haulm, and other materials for manure. By this time the muck-pits are generally full of grass-mowings and other summer sweepings; but the economical gardener will never waste a scrap of anything that can be rotted into compost, and room must be made now for the extra supplies. It is a common thing to see rubbish thrust into holes full of water, in order that it may rot the quicker, the parties forgetting that water washes out all the goodness of the material. It would be better to accumulate vegetable refuse in one large heap, to undergo fermentation and decay without the help of adventitious moisture; and if any offensive smell results, throw a layer of earth over the heap. Common mould is the best of all deodorizers.

Flower Garden

AUCULAS.—It is usual to repot and revise the whole stock before winter, though many growers prefer to repot in spring. As the Emmerton quackery has long been exploded, we need not do more than advise the use of a *sound and sweet compost*—garbage and goose-grease no one will now use. Sandy loam, containing a goodly proportion of decayed grass-fibre, with a third part added of rotten cow-manure, will grow them to perfection. Turn them out carefully; detach the offsets without making bad wounds on the old root-stocks; cut away any decayed parts of the roots; and in potting keep the collar well up, and press the soil in round the roots quite firmly. It is of the utmost importance to place them where worms are not likely to get into the pots.

CARNATIONS AND PICOTEES not yet layered must be attended to, or it is impossible for them to be well rooted before winter. A little bit of quackery lingers in this department, which we must hope to get rid of. We allude to the barbarous practice of removing leaves beyond such few as must be taken off to allow of fixing the layer. It is impossible to cut the tongue and lay down the shoot nicely without removing a few leaves, but let a few suffice, and do not indulge in removing any not immediately in the way, or in cutting the ends of such as are allowed to remain.

ARCADES.—At this time of the year most gardeners find themselves in arrears in regard to some departments of their work; but as little watering is now required, and there is a momentary lull in the activities necessary to keep gardens in order, all hands may be piped to clean out pits and houses, improve shrubbery borders by introducing plants to give effect

during winter, and various odd jobs in propagating, &c. Read over the notices of the past few weeks, and see what has escaped attention, as, with the fine weather now before us, lost time may be made amends for by those who are diligent and vigilant.

HOLLYHOCKS to be propagated from cuttings as soon as they can be got from the stool. Cuttings from the stems are of no use to amateurs, and should never be used by anybody except to increase kinds in great demand.

BEDDERS can only be kept in good trim by constant attention. Remove seed-trusses, yellow leaves, and rank growths. Put in cuttings of whatever is required, and pot off those already rooted. Shut them up for a week, and then expose them to all weathers till the time to house them. A few cuttings of *Perilla* and *Coleus Verschaffelti* put in now, and carefully treated, will make nice plants to group with *Chrysanthemums* in the conservatory by-and-by. These two easily managed foliaged plants should be grown in every stove during winter.

EVERGREEN SHRUBS may now be moved with the best chance of success, whether they be large or small. As to evergreens, such as hollies, aucubas, laurels, Portugal laurels, laurustinus, arbor-vitæ, &c., they have all done growing, their wood is hard, and if lifted now will make fresh root while the surface soil is in the best condition of warmth and moisture of any period of the year. Where new gardens are being laid out, the gain of three months upon the ordinary planting season is no small matter, as it enables the planter to get the chief operations finished at a time when the men enjoy the work, and the proprietor is enabled also to enjoy the result, and all to the advantage of the plants. Layers and cuttings of hardy shrubs put down now, and left till April or May, may then be removed, and planted in nursery rows with good roots.

PROPAGATION OF HERBACEOUS BORDER FLOWERS is an important matter just now, as there is still time to obtain a good growth of many subjects before winter, but no time to spare. Seed sown immediately of any and every kind of hardy perennial that can be grown from seed will have a fair chance, though for many subjects an earlier date of sowing is to be preferred, but as regards the safety of seedling plants during winter, the *late-sown* plants, generally speaking, are the most hardy; those that are fat and strong are the first to perish during very severe weather. Subjects that may be increased by cuttings may also be dealt with now, and frames may be filled with but little labour, and the certainty of a good return. Such things as the perennial species of *Iberis*, *Arabis*, *Centranthus*, *Dianthus*, &c., &c., may be multiplied without frames by selecting a shady spot, and there making a bed of sandy soil for them; and having put in the cuttings, shade them with mats or evergreen boughs for a few weeks, after which they will take care of themselves, and may be forgotten till next spring. No, not forgotten; it is bad policy to use that word, for if really forgotten the stock may be lost through the overpowering growth of weeds, which always start up in myriads in newly-made beds of sandy soil. Keep down the weeds therefore, and look at your stock occasionally, and never forget them.

LAYERING ROSES.—The old method of propagating by layers is a certain but a somewhat slovenly method, which rarely produces plants equal to those from cuttings or eyes; but it is capable of some improvement as generally practised, the object being not merely of obtaining roots, but well-shaped plants from the first. The usual plan is to make a tongue on the under side of a shoot, remove an inch depth of earth, corresponding with the position of the tongue, and then fix the shoot with a peg, and leave it to take its chance. Generally the layers root at the tongue in the course of three weeks, and if soon after removed there is a fair chance that the majority are living and doing well; but the plants are generally one-sided things that need a deal of care and patient culture to render them fit for the rosery. Let us endeavour to explain the best method of layering. Select the shoot which can be most easily brought down, and, before cutting the tongue, remove the soil, and fix it by a peg, so that there will be no fitting to do when the tongue is cut. When all is ready, cut the under-side of the branch across about one-third of its thickness, then cut a tongue each way, about an inch long, so that when the shoot is bent upwards the top strip of uncut bark will suffice to hold the two parts together. Bend it gently, and bring it to an upright position, and then drive down a peg; a small forked branch of a tree is the best for the purpose. But generally an upright stake to maintain the shoot in its proper position will render a peg unnecessary, or a strip of bast passed over the bent branch, and fixed in the ground by the means of a stone pressed upon its ends, will suffice to keep it from springing up, or breaking the top strip of bark above the tongue. It is much easier to root roses in this way than to keep them afterwards. Our advice to all painstaking rosarians is to pot every plant as soon as rooted; they will then have more attention than they would get in the open ground; they will have a lighter soil to promote the formation of a mass of roots; they will feel the check of being lifted less because they can be shaded and aprinkled; and when winter comes they will be ripe in the wood and safe from harm. Perhaps you can remember having many a time propagated roses from layers, and then lost the greater part during the winter. In future deal with them from their first roots as here set down, and if they have but one fibre each they will make good plants.

PRESERVATIVE WALLS FOR TENDER PLANTS.—When the mists of autumn warn us of the approach of winter, we begin to consider if our glass is sufficient in extent for sheltering all the tender plants we possess. To insure an exotic to the rigours and changes of our seasons requires some considerable time and preparation; it is not reasonable to suppose a plant can in one or two years so change its constitutional habit as to withstand uninjured either the one or the other, for it may be that the periods of excitement and rest natural to it are directly opposed to our seasons; so that to effect this, the first and most material alteration in the character of the plant, time is the principal agent. In most cases it may be forwarded a good deal by employing a medium position for the first exposure; that is, such a situation in which only part of the severities may be felt; and it is this which creates the value of conservatory walls: standing out in this manner, with properly constructed screens and other means of protection, the plant enjoys through the growing season an abundant supply of food; and if managed so as to be allowed the necessary time to elaborate and mature its required secretions, there will be but little danger of its receiving any material damage through the winter season. The construction of these walls must be determined in a great measure by the description of plants intended to place against them. For many of the finer sorts of greenhouse plants it is necessary that flues be added, and, indeed, a glazed front; but as this is an expensive erection, and we are not now writing for those who can employ an architect, we will reduce the scale

of our ideas, and suppose a wall to be standing, rather an unsightly object perhaps, and which it is desirable to cover; we will suppose also that camellias form a principal part of the subjects intended to plant against it (if deciduous shrubs are used, it will be much easier); the situation should be one facing to the south-east or the south-west, either of which is preferable to due south. The first proceeding will be to prepare the border; the natural earth, unless very good, should be removed to the depth of about two feet and a half, a third of the excavation should be filled up with stones and brick rubbish, to drain off superfluous moisture; this is the most important part of the whole, for if the bed is not thoroughly cleared of any excess of moisture, all other endeavours will fail. On these stones a thin turf may be laid all over, to prevent the earth falling between them. A mixture of loam and peat, with all the turf-sticks, &c., contained in it, should be well chopped with the spade and mixed with some rich garden-mould; this will form a compost to fill up the remaining space, and in which almost any plant will thrive. Immediately after planting, the whole bed should be well watered; but it is preferable to defer the nailing and training until the plants have taken a little hold, after which they should be extended as far as possible, and pruned rather thin, that the new branches may have the full influence of sun and air. The means of protection to be used through the winter should be of the simplest construction possible. A light wooden rail, fastened to the top of the wall, from which slanting pieces depend, to the ground, at a distance of about four feet from each other, and the lower end projecting about the same from the foot of the wall, will be all the framework necessary, on which a piece or pieces of flexible canvas may run by means of lines and pulleys, so as to allow of its being rolled up or down easily. The use of continuing the covering so far from the base of the wall is to retain about the plants the radiated heat given off from the surface of the earth beneath the canvas. With this simple contrivance, which may be removed entirely in summer, very many fine plants may be grown to a greater luxuriance than is often seen when completely under glass. In the management of these walls it must be particularly observed to avoid anything like an early excitement; in the early spring months we frequently have a few hours of hot sunshine succeeded by cutting winds or frost. These changes are more injurious to the plants than the severest continued weather, from the action of the sun causing a reaction in the system of the plant, which, ever ready to recommence its seasonal activity, pushes its sap in a very short time to the extremities of the shoots, and there, on the succession of cold to this brief impulse, it becomes coagulated or frozen, and so distends the whole tissue of the plants as frequently to cause it to split; this must be carefully avoided, by refraining from exposing them to any weather likely to make them start until a prospect is opened of its lasting. There need be no fear if the plants do not even push till April or May, but that they will then do so with much greater vigour. On the other hand, the autumnal exposure should be maintained as long as possible, suffering them to receive all the influence of the sun, that the wood may be thoroughly ripened. With attention to these particulars success is made certain. The advantages derivable from this manner of growing plants are important, and easily made apparent, for beside the satisfaction of being able to grow handsome plants, where before only coarse climbers would succeed, or having valuable in the place of common plants, we must consider the ultimate effect produced on the constitution of the plant, and the increased probability of its being by these means induced to withstand all attacks, even without shelter; the received opinion being that all vegetation will endeavour to form its tissue in accordance with the situation and circumstances under which it is produced.

Fruit Garden and Orchard House.

STRAWBERRIES.—Now is the best time in the whole year to make new beds, to ensure good bearing next year. If rooted runners are plentiful, take the best only, and destroy all the weak ones; but with any varieties it is thought desirable to propagate to the utmost, sort the runners as to sizes, planting the forwardest and strongest in beds to bear, and the late weaker ones in separate beds for stocks; these latter will not probably bear till the year after next, and then will be strong plants. Strawberries to fruit in pots next year ought by this time to be strong, and in need of a shift. The soil should be strong loam, well chopped over with rotten dung, and the plants to be potted firm.

Greenhouse and Conservatory.

PELAGONIUMS that have been cut down and made new shoots an inch long must be repotted. Don't shake the earth off so as to destroy the ball entirely, but remove the outside, and trim in the roots slightly, so as to get them into small pots. Those potted a month ago now want a shift. Take care to have a sound compost; the use of light sandy composts has much to do with the long joints and weak flower-stems we notice at the shows.

REFRESH all specimen plants in pots that are not to be shifted, by removing the top soil, and adding a dressing of new material—sheep's dung for those that can stand it, rotten dung from a cucumber pit for Camellias, Allemandas, Stephanotis, Dipladenia, &c.

PLANT-HOUSES of all kinds should now undergo a thorough purification, and all necessary repairs should be completed, that all may be dry and sweet before fires are lighted, and shelves are crowded with plants. The neglect of these matters until the drenching autumn rains occur is common enough and had enough. At the present time any kind of plants may be set out of doors if needful, or room may be found for them in other houses while repairs proceed. But in a few weeks hence it will not be so safe to turn things out, nor will there be so much room to spare in houses only partially occupied.

AMARYLLIDS FOR WINDOWS.—The gorgeous amaryllids are not near so generally cultivated as they ought to be, considering how easily they are managed; there are numbers of them that would succeed to admiration with careful window treatment. *Vallota purpurea*, *V. p. major*, *Amaryllis aulica* and its varieties, *A. vittata* and its varieties, *A. psittacina* and its varieties, *Hæmanthus coccinea* and *viridiflora*, *Nerine undulata*, one or two of the *Sprekelias*, and the lovely *Cyrtanthus obliquus*, would all succeed well with the careful treatment bestowed on their plants by many window gardeners. The chief item in their culture being, as soon as they manifest signs of growth after a season of rest, shake all the old soil from the roots, and repot in equal parts loam and very well-rotted manure or leaf-mould; Wanstead loam is the best for them. For cultivators near London this is easily procurable, but any rich friable loam will answer perfectly; eschew peat, excepting for *vallotas*, but it is by no means indispensable for them; neither is sand necessary in the cultivation of amaryllids. They make without exception thick, strong, fleshy roots, and

imbibe through their hungry spongioles all the nutriment that can be supplied to them. They should in fact be treated just as we treat onions in the kitchen garden, of which, if we desire a good strong crop, we trench deeply, and manure heavily for them. In potting amaryllids complete drainage is of the first importance; two crocks laid over the hole in the pot, one half way over the hole, and the other resting upon that, with a quantity of small chips of broken pot or oyster-shell to cover the rest of the bottom part of the pot, and a layer of the fibre of loam or peat over that, will be perfect; if in addition cracked pots are used, the very acme of perfection will be attained as regards drainage, and the results will be proportionally favourable. Having repotted, water moderately until vigorous growth has commenced, when water may be more frequently supplied; place the plants in a warm window, in the fullest light, and let the foliage have every chance of developing itself according to character. When the tips of the leaves begin to turn yellow, let water be gradually withheld till they are quite dead, and then place the bulbs, pots and all, in a dry warm cupboard, or some such place, until they show flower or begin again to grow, when the routine of shaking out, &c., must be again gone through. Those that have persistent foliage, as *Amaryllis aulica* and *Cyrtanthus obliquus*, must be attended to with water all the year round, although but very occasionally in the dormant season. The possessor of a greenhouse may of course cultivate successfully many varieties and species of the genera we have been treating of. *Amaryllis aulica* is so accommodating a subject that it will grow in a common greenhouse, year after year, and break the pot by the expansion of its roots, just in the same way as the familiar *Agapanthus umbellatus* does, and certainly a large pot of it suffered to go on year after year without division becomes when flowering a truly magnificent spectacle. It is somewhat capricious, flowering indifferently at almost any season.

Stove and Orchid House.

ORCHIDS require peculiar care now to secure a perfect ripening of the growth of the season, and to prepare them for their winter rest. A general reduction must be made in the supply of moisture, and a general increase must be allowed of solar light. The cultivator will, of course, guard against any extreme in drying up or exposing to sunshine; a certain amount of moisture will be required even when the plants are perfectly at rest, and some more than others. It is certain that at this time of year shading should be used quite sparingly, and a condition of repose should be encouraged by a reduction of the temperature and the amount of moisture.

WALL TREES.—The principal duty of the cultivator now is to assist the trees in any way that may be possible in the ripening of the wood. Where the walls are covered with glass, the lights should be wholly removed; where the walls are overloaded with wood, some of it should be thinned out; where nailing has been neglected it should be completed at once.

GESNERA ZEBRINA to flower in winter will require a shift this week. The compost to be equal parts hazelly loam, fibry peat, and leaf-mould. Keep shaded and warm after shifting, and syringe frequently.

Forcing Pit.

PEACH-TREES that were forced early should now be fully exposed to the atmosphere, and this can only be done by taking off the lights. This not only tends to a complete maturation of the wood, but prevents the trees becoming infested with red-spider, the attacks of which pest causes an artificial and premature ripening of the wood, which is not to be desired. Now is a good time to whitewash back walls, and when the lights are off to repair and paint them.

VINES.—The leaves of vines that have been forced early too often become brown and shrivelled at this time of year through increase of red-spider. Some cultivators comfort themselves with the idea that the wood will be better ripened in consequence, but that is a great mistake. Insect pests do no good, direct or indirect, and the careful cultivator will do his best to get rid of them by means of sulphur and such other remedies as are constantly recommended. It is always a proof of bad management when the leaves of vines become prematurely withered.

PINES swelling their fruit to have frequent supplies of liquid manure, and abundance of atmospheric moisture. Young plants to stand the winter, for fruiting early next year, had best be removed from those swelling fruit, so as to keep them drier and more freely ventilated.

THE LORD OF THE HARVEST.

"They that sow in tears shall reap in joy. He that goeth forth weeping, bearing precious seed, shall doubtless come again with rejoicing, bringing his sheaves with him."
—PSALM cxxvi. 5, 6.

The time for toil has passed, and night has come,
The last and saddest of the harvest eves;
Worn out with labour long and wearisome,
Drooping and faint, the reapers hasten home,
Each laden with his sheaves.

Last of the labourers, thy feet I gain,
Lord of the harvest, and my spirit grieves
That I am burdened not so much with grain
As with heaviness of heart and brain;
Master, behold my sheaves.

Few, light, and worthless—yet their trifling weight
Through all my frame a weary aching leaves,
For long I struggled with my hapless fate,
And stayed and toiled till it was dark and late,
Yet these are all my sheaves.

Full well I know I have more tares than wheat,
Brambles and flowers, dry stalks, and withered leaves,
Wherefore I blush and weep, as at thy feet
I kneel down reverently and repeat,
"Master, behold my sheaves!"

I know these blossoms, clustering heavily
With evening dew upon their folded leaves,
Can claim no value or utility;
Therefore shall fragrance and beauty be
The glory of my sheaves!

So do I gather strength and hope anew;
For well I know thy patient love perceives
Not what I did, but what I strove to do—
And though the full ripe ears be sadly few,
Thou wilt accept my sheaves.

Replies to Queries.

X. Y. Z.—We really cannot give an opinion until our samples are further advanced.

Box Edging.—T. H.—As you have a great deal to do, begin at once. Plant a good length at a time during moist weather, taking care not to have the plant lying about more than can be helped.

Fuchsias.—Barnard Castle.—Madame Cornelissen may be shown in any collection or class, if there is no special requirement as to colours; but if fuchsias are classed as Light and Dark, then it belongs to the Light class.

Club in Cabbages.—H. A. C.—Whatever enriches, refreshes, and renews the soil will tend to abelish club. We grow brassicas of all kinds on an old plot where club formerly prevailed, but is now scarcely known, having been got rid of by good cultivation, one feature of which has been abundant manuring. Deep digging and plenty of manure will do more to eradicate club than all the nostrums ever heard of—in fact, nostrums are not of much avail, because clubbing begins in the seed-bed. We advise you to sprinkle lime over the young plants as soon as they appear in the seed-bed, to practise deep digging, and when planting out dip the roots in a puddle of clay, lime, and soot.

O. P. May.—Your plant is *Crinum capense*.

Johnson.—If the tub is cleaned in a rough sort of way, and then coated with pitch inside, it will last a long time. Its greasy condition will not prevent its receiving the pitch. The outside may be painted, but not the inside. If you have a box made, it should be pitched inside.

J. B. Bowdon.—Your plant is right enough. You can scarcely give it too much water. Do not give it a larger pot till it requires more room; over-potting is dangerous.

Right of Government Surveyor to enter Private Grounds.—R. B. S.—The person who has applied to enter your grounds and make a plan of them is no doubt properly authorized, and might be allowed, without any risk of damage to your property, to carry into effect what he proposes to do. You have incurred no penalty in refusing him admission, but you will in due time receive a notice from the Ordnance Board demanding admission for its representative, and refusal will involve you in a liability to a fine of ten pounds.

Grafting Vines.—Subscriber.—The proper time for grafting vines must be determined by the condition of the stocks to be operated upon—as, for instance, if your vines have their roots in an inside border, and the house is kept moderately warm for a various collection of plants, they will, in all probability, be in a fit condition by the end of February. But if their roots are in an outside border, the second week in March is generally a good time. Specific rules cannot be given without seeing the subjects to be operated upon, but experienced hands graft much later than above stated when it is necessary. The branches from which the scions are to be cut should be preserved in a damp soil away from the frost. The annexed sketch will show how the scion must be cut, and the shape of the stock. This is what is generally called whip or tongue grafting, and is to be preferred by inexperienced hands to other methods, as it is not only more sure, but very simple in working out. We see no reason why a good clay graft should not answer with you; in fact, we should recommend it in preference to wax. In making up the clay, mix about a third of fresh cow-dung with it; this prevents the clay cracking when exposed to the air. When the clay has been firmly pressed round the

graft, bind round it a good handful of wet moss, and keep this continually moist until the clay is removed. With this little attention in the way of moisture, clay will be safer in the hands of amateurs than wax. Inarching is always to be preferred when practicable in such cases as yours, as not only the surest means, but the simplest.

Correspondence.

GROUND VINERIES.—I wish for information respecting Wells's portable vineries; indeed, your strong advocacy of them has almost tempted me to give them a trial. I have a vinery in two divisions, 34 feet by 13 feet, planted with twenty vines, and, in justice to my gardener, I must admit, never fails to produce me a good crop of large, well-coloured, and well-flavoured bunches. I have now a thought of turning the vinery into a greenhouse, and taking out the vines, which are planted outside, and lay them on the border, and place over each vine one of Wells's vineries—the vines are each about 16 feet long; but I am rather undecided whether to buy the twenty Wellsian vineries, or allow the vines to remain, and build a greenhouse. My vinery cost me £60, and I find I can have a greenhouse for the same money, stage included. Can I really hope to get as good a crop with the Wellsian arrangement as I now do with my vinery? I find the Wells vineries will be the most costly. My gardener, I must inform you, is prejudiced against them, and says that the grapes from the ground vineries exhibited at the Guildhall exhibitions were no better than could, with little care, be grown against a good wall in a good aspect without glass.

VITÆ.

[If you are in a perplexity about deciding between a house and so many ground vineries, we cannot undertake to fix your mind upon one or the other. We have really said so much on the subject of ground vineries that it would be waste of space to say anything more in their praise. It would be well for you, before deciding, to make acquaintance with the ground vineries made by Mr. Rivett, of Statford, Essex. As to the grapes shown by Mr. Wells at Guildhall, they were fair samples of Black Hamburgs, well ripened, and some forty or fifty bunches cut from about 30 feet run in a single rod vinery. If you refer back to our report, you will learn the exact particulars. When your gardener can get forty or more bunches from a 60 feet rod on a wall, the bunches averaging 1lb. each, and as well ripened as those of Mr. Wells's, we shall respect his prejudices. At present we hold to the opinion that ground vineries afford a certain and simple means of producing good table grapes; but you must decide for yourself whether to buy vineries or build a house. Perhaps it would be well to read the papers on the subject in "The Floral World" of April and June, 1866.]

We should like to hear from some of our grape-growing readers on the subject.]

VIOLA CORNUTA.—I have perused with much interest and edification your valuable papers on "Bedders" in your recent issues, and I can endorse, almost without exception, all your remarks upon special subjects; and in these remarks, according to my humble opinion, you have dealt with the Viola and its varieties as it deserves. But there is one circumstance connected with the plant to which you made no reference. Perhaps it may be the plant is not affected in the same way in other parts of the country as it is here in Battersea Park. In several of the beds here the variety Purple Queen keeps continually dying off, and I have examined the dying plants very minutely, but I am not at all sure what may be the real cause of such speedy decay. However, the stems of the plants are completely hollowed out by some insect, and in several of the hollowed stems I found some very small white soft worms, and also numbers of a very small roundish oval-shaped insect, appearing to the naked eye like grains of sand. If these are the depredators, there must be numbers of them invisible to the naked eye. I enclose part of a plant in its dying state, and would be thankful for information on the subject, if it is convenient, through your columns.

J. W.

Battersea Park.

BRISBANE BOTANIC GARDENS.

The following extracts from Mr. Hill's report, lately made public, will no doubt prove interesting to many of our readers:—

The tea-beds are planted to test the climatic effect on the plant in different situations; and, as recent intelligence informs us that the several attempts made to rear the tea-plant, both in Victoria and South Australia, have signally failed, it will, I imagine, be especially gratifying to all those who take an interest in the material prosperity of Queensland, to learn that the groups of tea-plants, both in easterly and westerly aspects, never exhibited a more vigorous, healthy, or exuberant growth than now. Some of the other beds comprise plants of allspice, tamarind, chocolate, crotons, &c., and all are giving evidence which encourage the hope that they can defy the severity of the Queensland winter. The ground which was set apart last year chiefly for the culture of oranges, vines, pine-apples, and any other choice fruits which it may be found necessary to produce in a secluded and sheltered situation, has been considerably enlarged.

During the year, the botanical treasures have been largely enriched by copious and very valuable contributions of seeds and plants from various parts of the globe, especially from Java. In the collection from J. E. Teijsman, Esq., director of the Botanic Garden, Buitenzorg, Java, was a Wardian case of cinchona plants, comprising three of the most valuable species, viz., *succirubra*, *Calisaya*, *lanifolia*, and accompanied by a sample of seed of the *C. Calisaya*. The next contribution which I have to acknowledge is a quantity of cinchona seed and a large variety of Peruvian maize, from C. Ledger, Esq.; also a very valuable case of bulbs from Messrs. J. Veitch and Sons, of the Royal Exotic Nursery, London.

I am glad to say that the desire which I have so long cherished, of successfully cultivating in the gardens the most valuable species of the cinchona, has at length been realized. Some of those received in the Wardian case from Java have been planted out in a sheltered and otherwise favourable situation; although not more than six weeks in the ground, they have made very considerable progress, and give every indication of adaptability to the soil and climate of Queensland. The seed sown, comprising three species (*succirubra*, *Calisaya*, and *officinalis*), has also germinated successfully, and hundreds of the plants will be quite ready for planting out in the ensuing spring. The Durio (*Durio zibethinus*), the bitter wood (*Quassia amara*), the chocolate (*Theobroma cacao*), and Croton oil plant (*Croton tiglium*), have likewise been transferred to their permanent positions, and give evidence of a most healthy and vigorous growth. Whilst on this branch of the subject, I think it right to observe that there are three or four of the new and most precious plants, such, for example, as the mangosteen, the vanilla, nutmeg, and clove, which I am inclined to believe, owing to the severity of a portion of our winter, would thrive much better a few degrees farther north; and with that view, and in order to insure safe provision for such very delicate tropical plants as the colony might receive from time to time, I would respectfully suggest that a piece of ground should be set apart—say at Rockingham Bay, or at some place in that latitude—as a nursery plantation under the special direction of the Government. A considerable number of these plants are now (March 28th) ready for removal, and if a plantation such as I suggest were ready to the north, the ensuing spring would afford a most opportune time for transporting them thither, together with collections of the cinchonas and other rare and valuable plants.

The donations of maize, numbering in all 130 varieties, forwarded specially for experiment, have been carefully tested, and in no instance have they equalled, much less exceeded, the maize commonly cultivated in the colony. The large Peruvian, the only variety from which great things were expected, and which, from the size it attained in the first stages of growth, induced a belief in its superiority, proved to be a failure in the gardens; although I hear from one person to whom I distributed some of the seed, that it produced remarkably well in the neighbourhood of Ipswich. Those in the gardens grew to a great height, some of them upwards of fourteen feet, but, singular to say, very few of them yielded more than one cob, and that was so diminutive in bulk and thinly grained as to render it scarcely worth the trouble of gathering.

Of the useful trees already growing in the gardens, I may mention the following as having fruited and seeded for the first time during the year—a fact which may be regarded as the best proof of their effectual acclimatization, viz., allspice (*Eugenia pimento*), Avocado pear (*Persea gratissima*), tallow tree (*Stillingia sebifera*), cherimoly (*Anona cherimolia*), and Mango (*Mangifera indica*). The trees and shrubs which I noticed in previous reports as having fruited and seeded continue to produce excellent crops, the size and quality of the fruit increasing as the trees advance in maturity. The coffee shrubs have yielded this season an unusually large and fine crop, and continue to be a general subject of admiration among visitors. The Indigo, cinnamon, cotton, sugar, tobacco, ginger, cassava, &c., are in a flourishing condition.—WALTER HILL, Colonial Botanist, and Director of Botanical Gardens.

SUBSCRIBERS TO THE GARDENER'S MAGAZINE who desire to extend its sphere of usefulness, and are willing to interest themselves in promoting its still wider circulation, can materially further this object by sending to the publisher the names and addresses of persons they think are likely to become subscribers, who will forward to each a certain copy free. A stamp must accompany each name and address sent, to cover the postage of the specimen copy.

The Gardener's Magazine.

SATURDAY, AUGUST 24, 1867.

THE CULTURE OF THE AILANTHUS has been regarded as offering a new industry for this country, and many experiments have been made with a view to the development of the plant, and the celebrated Japanese silk-worm-moth, *Bombyx cynthia*. In some parts of Britain the tree grows vigorously; indeed, in the southern counties, and in the neighbourhood of the metropolis, it is one of the healthiest and handsomest of trees we possess. As to the moth, we are not prepared to say that the question of its cultivation in this country is settled, but we cannot any longer hesitate to express our belief that the idea of acclimatizing it with a view to the derivation of a profit from its cultivation is a delusion. We have been watching for some time past a series of experiments in "Ailanti-culture," and it appears to be full time to warn those who are bitten with the silk-growing-in-England frenzy to limit their operations to the means at their disposal, with the certainty that in a commercial point of view this business is a failure. We have lately inspected an Ailanthus farm of considerable extent. Our readers may not be prepared to hear of a seed-bed of trees and silkworms 400 acres in extent, but, as a matter of fact, we write this from an Ailanthus farm of larger dimensions than that, and we speak of 400 acres specifically, because that was the breadth of land planted in the first instance. The farm comprises 700 acres in all; but Ailanthus is now an accidental weed of the place; wheat, barley, oats, peas, and green crops have usurped the places of the silkworms, and the land is at last put to a nobler use than the growth of silk.

Yet there was at first a glorious promise of success. In 1864 and 1865 the results were so far satisfactory that preparations were made for enlarging the operations of the farm, but in 1866 and 1867, both cold seasons, the scheme received its death-blow, and where Ailanthus grew sheep-feed now occupies its place. It was anticipated that about two pounds per acre clear profit might be derived; and, though this has never been attained, the results of the cultivation in 1864-65 were such as to warrant the belief that poor land, unfit for farming, and producing perhaps less than six-pence per acre, might be made profitable by means of *Ailanthus glandulosa* and the now famous moth *Bombyx cynthia*. But so bright a prospect is now overshadowed. The 700 acres that were intended to supply the market with English-grown silk have changed their aspect: the ailants have been ploughed out, the worms discarded, and farming of the old sort—the growth of beef and mutton—will quickly supersede the growth of silk.

The case may be understood by means of a few particulars. As to the growth of the Ailanthus, it is necessary, for the welfare of the worm, that the trees should be kept dwarf, for on tall trees the worms are apt to be blown down by a gale, and to be eaten by thrushes and blackbirds. The annual cutting down of the trees reduces their vigour, and in the event of a severe winter a large proportion of them perish. So also, in respect of the moths, a cold season not only keeps them back, but actually destroys them. The result of a combination of adverse influences is that *Bombyx cynthia* takes the place of the mulberry silkworm; it becomes a toy, and as a toy it must henceforth be cultivated in this country; and those who are bitten with the Ailanthus frenzy must be content with a toy. There is no prospect, so far as we understand the case, of it ever becoming a commercial success. We commend these few remarks to the consideration of our excellent friend, Dr. Wallace, of Colchester.

THE DRACÆNA.

Whatever good the sub-tropical movement may have done in other respects, it has certainly not advanced this beautiful plant one item in the estimation of the general public, for it is with some difficulty that any one can recognise the lovely *D. terminalis*, which is the sort most popular amongst sub-tropical disciples, in the dirty red or brick coloured objects whose leaves rustle in the passing breeze. They look as though every particle of life and vitality were blown out of them, which, I apprehend, is very nearly the case by the end of the season. There is nothing to encourage us in bedding them out in the appearance of those which we meet with wherever the system is carried out to any extent. It will hardly

be worth while to enter at any length into the matter, but I cannot refrain from saying that, so far as my own opinion is concerned, I would a thousand times sooner see a good bed of geraniums, verbenas, or other bedding plants—or if these things are not exactly suited, a bed of variegated hollies, or other ornamental shrubs—than a lot of stove plants stuck out in the open ground to die a lingering death, or, at all events, to present such a miserable appearance as would lead one to desire a speedy death for them. Therefore I shall confine my observations upon the culture of the plant in question to those points connected with its requirements in the stove, and its use in the decoration of the conservatory. Very few plants can be grown so easily as this, provided a reasonable command of heat is obtainable, and also a supply of proper soil. It is very little use to think of growing the stove species into handsome specimens without these essential requisites, for if the plant makes a little growth through the summer, and it has to be wintered in cold quarters, it will certainly lose all the leaves with the exception of a little tuft on the top. I have often seen plants in that condition—yes, I may safely say dozens of times—and very often people are at a loss what to do with them, and as they are generally considered to be rather valuable in a pecuniary point of view, they are afraid to cut them about, whereas few plants stand the knife so well. Now if I wanted to get up a stock of plants, *D. terminalis* is exactly the subject I should like to get hold of, no matter if it were as tall as the Nelson monument in Trafalgar Square, provided it had life throughout its length. Supposing any one has a plant of this description, the best thing to be done will be to cut it down to within a couple of inches from the level of the soil, and cut the stem into lengths of three inches each, and pot them firmly in large sixties, in peat and sand (the top piece with the leaves should not be too long, or it is a long time in taking root), and the pots plunged in a strong bottom heat, if obtainable, and I will guarantee every piece to grow and make a plant. If more plants are required than the number of pieces of the stem, the young shoots, which will break out of the top eye of each piece, should be taken off with a heel of old wood attached, and inserted in a pot with soil as recommended, with the addition of a layer of silver sand on the top, and be at once covered with a bell-glass and plunged in bottom heat. As fast as the buds push, the young shoots can be taken off and treated as before. Every eye will break if the shoots are taken off as fast as they attain a sufficient size to handle: a dozen or more can be obtained in this way from the old stock, if necessary. The thick, fleshy, tuberous-like root, which strikes direct downwards to the bottom of the pot in old plants, will make a plant, if carefully cut from the parent, and the part which was downwards in the old plant potted upwards and covered with half an inch of soil. This piece should be cut about an inch and a half long. I have often turned established specimens out of their pots, and taken the root off without the plant appearing to suffer the slightest check.

I have gone into the subject of propagation in this paper more fully than may appear necessary, considering its simplicity and the ease and certainty which attends the operation. I might have summed it up by saying that the plant is increased by cuttings, and nine-tenths of the readers of this, whose knowledge of the *Dracænads* is limited (exactly the people for whose edification this is contributed), would most assuredly be in difficulties as to what source the cuttings are to be obtained from. I do not attach the slightest importance to any particular season of the year for taking cuttings, for I have found them to strike with unvarying certainty all the year round, provided sufficient heat is obtainable. The routine of culture is as simple as anything can be after the plants are struck. As fast as the plants grow and fill the pots with roots they should be repotted, using equal parts of peat and loam as lumpy as can be conveniently obtained, and a good sprinkling of silver sand. But it is best not to overpot them at any stage of their growth. The temperature of an ordinary stove will suit them, and water must be given with discretion, and they are quite as well syringed overhead, although they luxuriate in a moist atmosphere through the spring. After June my plants have to take their chance in the conservatory up to the end of September, when they return to their winter quarters. During the time the plants are in the conservatory they should be carefully watered, for if they get too much the bottom leaves will soon fall. In the winter they should undergo as little excitement as possible, for the growth made during that dull period is too

delicate to stand, and soon gets spotted and spoiled. As soon as any flowers make their appearance the spike should be nipped out. Although the flowers push from the top of the stem, and would perhaps lead one to suppose that the plant would have to make a side shoot, it does not interfere the least with the symmetrical proportions if it is removed at once, and no one would be able to see that it had bloomed at all. It is quite a matter of taste as to how many plants are grown in a pot, whether one or a dozen. Red-spider, thrip, and green-fly will attack the *Dracæna* if grown in an atmosphere too hot and dry. The two latter pests can be destroyed by fumigating with tobacco paper, and the former by sponging the leaves with Gishurst compound. Take a lump of the compound and wet a sponge and rub it on the compound, wash the leaves over with it, and, finally, wash the plant over afterwards with clean water. The thrip can be destroyed in the same manner if the house does not require smoking for the other plants. The different species of the richly-coloured kinds are certainly very similar, and these remarks are exclusively intended for them. *D. Cooperii*, *D. ferrea*, and *D. terminalis* are splendid kinds, and worth room in the best stoves in the country.

GEORGE GORDON.

A CHAPTER ON MANURES AND MANURING.

The manures employed to fertilize the land are divisible into two kinds. The first are the mineral; the second are the vegetable and animal.

To place the argument relative to this important part of agriculture on a solid foundation, a few specimens of those soils that have been always esteemed by persons in their neighbourhood the best and most fertile are laid before the reader, and comments will afterwards be made upon them.

First. Out of nineteen parts of an excellent wheat soil:

14	parts of silica, or large, small, and fine sand.
2	" lime, or carbonate of lime.
2	" alumina, or clay.
1	" vegetable and animal matter.

Second. Out of twenty-five parts of a turnip soil:

20	parts of silica.
2	" lime.
1	" clay.
2	" vegetable and animal matter.

Third. Out of ten parts of a fertile soil from Scotland:

3	parts of silica.
1	" lime.
5	" clay.
1	" vegetable and animal matter.

Fourth. Out of eight parts of a soil proper for wheat:

2	parts of silica.
3	" lime.
3	" clay.

These four specimens are sufficient to answer the purpose intended; for although there is no doubt as to the correctness of their analyses, since they have passed through the hands of Sir H. Davy, yet they will by no means serve to constitute a general scale of productive proportions; because a variety in the subsoil, as well as a difference in the situation and climate, must ever defy the establishment of one scale only. However, the above will answer every reasonable purpose; but first an opinion should be given as to a standard of fertile proportions which can be safely relied upon, and capable of practical adoption. It is this: to select the proportions from the best soils in the very neighbourhood of the field to be improved, where the subsoil and situation are similarly circumstanced, and the climate the same.

On viewing the proportions of silica, lime, clay, and vegetable and animal matter in the specimens selected, we are not a little surprised at the smallness of the quantity of the vegetable proportion, which on an average is only as 1 to 15; therefore, one directly decides that the permanent fertility of soils is by no means dependent alone on the vegetable share of matter they contain. This, however, must be proved; and to do so it will be necessary to estimate the produce of fertile lands, say for the space of four years; and it will soon be found that the vegetable proportion alone is far too small in quantity to insure such abundant crops as the following:—

First year. Turnips that will fat ten sheep an acre.

Second year. Barley seven quarters, or oats eight to ten quarters to the acre.

Third year. Beans four to six quarters to the acre, or two good mowings of clover.

Fourth year. Wheat four to five quarters to the acre.

All this from one coat of manure of the vegetable kind, and applied at the fallow.

Now, the usual coat of vegetable manure on the best regulated farms never exceeds in general, and indeed seldom equals, all the straw even they produce; because, when an agriculturist can manure a quarter of his land each year—that is to say, return all the straw grown on each field every four years—it is as much as he is able to accomplish; and this quantity is found, from experience, amply sufficient, when conjoined with the fallow, to raise healthy and productive crops. This being the case and the fact, the more weighty and valuable part, the corn, which is sold off from the land as food for man and beast, except what may be consumed at home, does not more than compensate for the loss of straw by thatching, by tithe taken in kind, and by waste, which will ever unavoidably occur on every farm under even the best management.

Whence, then, does the growing corn acquire the extra and necessary supply, since, as above shown, it cannot be from the vegetable manure alone which is carted on, because that would be obtaining a greater quantity from a less. Is it from the materials of the soil? Yet, how can that be? for, if we were to allow it to be the case, the fertile soil must, in the course of a few centuries, be reduced in quantity, and thus deprive future generations of the means of support, being contrary not only to present facts, but to the usual providence of the Supreme Being. And, as regards present facts, the best soils in former times are now, under proper management, equally as productive, if not more so, than then. The necessary

supply of food must, however, come from somewhere; consequently we must look and examine around for the source or sources; and if we do look, it must be for that which is known to be necessary to plants, is within their reach, and of a nature inexhaustible.

They are then, as has been before shown, and here again confirmed, the rain, the dews, and the air, all of which falling upon, and entering into a pulverized and fermenting soil during the process of the fallow, and thus expelling, as has been also before stated, the stale air and stale water which has been breathed by preceding plants. Just in the same way as gathered flowers in a glass of water on a mantel require the water to be changed every day or two, or they would droop, so a store of fresh air and fresh water, with renewed powers of fermentation, is acquired by the soil. This takes place with fertile soils, and those in good heart, at the time a crop is growing. The fresh water, in proportion as it is absorbed by the plants, gives place immediately to fresh air, or a vacuum must ensue: therefore these two great advantages arise, whenever a shower falls, or the night's dew enters the fertile earth; and thus the rapid growth and improvement of vegetation in the growing period of the year, after every kindly shower, is accounted for. These, conjoined with the influence of the sun, the seasons, and the innate powers of growing vegetables, aided no doubt in some degree by the principles of electricity, effect the formation of corn and fruit.

Relative to the expulsion of the stale air, &c., which is so important, it is in proportion to the quantity and the general diffusion of the rain throughout the soil; and this is, of course, in proportion to the state of pulverization, or adhesiveness of the particles of the soil, and its nearness to the last ploughing. The strong analogy between the soil and the stomach of animals may not improperly be adduced as an illustration of the above argument. The soil does not of itself afford the means of support to the plant, but receives the food from the vegetable manure carted on, and from the rain, dews, and air; so the stomach, by the animal's industry in gathering or catching its food, merely prepares it by a decomposing process, which so far weakens the several affinities of the matter contained, as to be capable of being afterwards selected and taken up by the appropriate organization of the plant and the animal: and this is effected in proportion to the proper constitution and health of the soil and the animal.

This constitution of the soil, then, is of the first importance, for upon it depends the power of decomposing vegetable materials within itself, and of abstracting from the elements that come within its sphere the other requisites for the support of plants, all of which the soil retains with that gentle degree of combination which the selecting energies of vegetation are able to overcome.

Two sources, then, of food for plants are available by man: the one, manure, carted upon the soil; the other the surrounding elements. Both these are had recourse to by the practical husbandman, sometimes alone, as in carting on the manure, or making a fallow; and sometimes conjoined, as when manuring the fallow.

Of the subject of this chapter—the manures.

Of the mineral kinds, are lime, sand, burnt earth, clay, marl, hedge-mould (which contains much vegetable matter), or any other of the earthy or mineral substances, which upon inspection are all easily resolvable into the three principal ingredients of the soils namely, lime, sand, and clay.

As respects the use of these mineral and earthy materials to improve soils, they can only act, in the first place, to strengthen the constitution and permanent digestive powers of the soil, by increasing the deficient proportions of either lime, sand, or clay; and it is in this way that they add to the permanent fertility. If there be no deficiency, they then can only prove of use to hasten the decay of vegetable matter, which is preserved in a strong balance of affinity by acids, and which lime has the power of neutralizing; or from the freshness occasioned to the soil by the application of those substances that have not been under the influence of growing vegetables before, at least not of corn. This fertilizing effect is, however, but transient, and the application of the materials oftentimes expensive. In fact, this practice is precisely similar, only less effectual, to the benefit gardeners experience with their plants when repotting them into fresh mould; and the agriculturist's cheapest and only practicable substitute, where the soil is properly constituted, is in a one year's well cultivated and vegetable manured fallow.

Animal and vegetable manures next claim attention. These are, dead animal matter from the inhabitants of the land and sea, including bones &c., and the vegetable materials, of every denomination, found growing on the earth, some of which are ploughed in green; others are partly decomposed before they are applied. But the description most generally employed is the straw of all corn and grass, trampled down in the farm-yard by stock, and impregnated, more or less, with their excrement, which improves the strength of this kind of manure in proportion to the nature and quantity of the food given.

Soot is a manure partaking of both the animal and vegetable, being composed of ammoniacal salts and empyreumatic oil, with a great basis of charcoal, substances which are readily decomposed by the action of oxygen and water. This manure is generally applied as a top dressing; but the animal and vegetable manures are always ploughed well into the soil of all arable lands, and laid on the surface of pastures in autumn and spring.

Since the animal and vegetable manures are composed of the materials needed by growing plants, even to the very earths and salts, of which soils are said to be robbed, they must consequently afford the most valuable share of food to growing plants in the readiest state for their selection; but as the food, from its capability of being consumed by living vegetables, is continually diminishing, the consumption requires making up by periodical fresh applications.

Animal and vegetable manures being most generally used for the enrichment of soils, it is useful to inquire what changes and consequences arise when they are thus employed.

The usual method of application of farm-yard manure is, by carting and spreading the materials on the surface of a field, in an incipient state of decay, and then burying them in with the plough.

Experience proves that the decomposition of vegetable and animal manure is in proportion to the state of culture of the land to which it is given. If the field be in an exhausted state, and only one ploughing follows just to bury the manure, its decomposition and chemical and mechanical union with the soil will be very slow, in consequence of the undisturbed strong balance of affinities of the impoverished soil.

If the previous reasoning holds good, manure so employed is in part wasted, instead of being made the most of, as it is when put early on a fallow: because the manure when buried lies in contact for a whole year

with precisely the same surfaces of the soil, and, being in lumps, its sphere of contact must be proportionally small. The consequence is, that less fermentation takes place than there ought to be, and a proportion of the manure will actually escape in gas from its own fermentation after the saturation of the contiguous particles of the soil has been completed, and the absence of more fresh particles to arrest it. If plants are growing above it, they are injured from the "apoplexy" and lodging of the corn that follows, by receiving this food too readily, and that not sufficiently diluted, if I may be allowed this expression. This is the reason why fish manure, or yard manure, is so soon gone when put on a field to be immediately cropped, and is not cultivated previously.

Stubbles ploughed in will remain with very little decay for a whole year in poor and half cultivated lands, from the existence of the strong balance of affinities, resulting from the exposed particles being saturated, and no new ones being brought up to the sun, air, &c., therefore no fresh combinations or fermentation can take place. Whereas, if stubbles are ploughed in preparatory to a fallow, so as to have the benefit of several successive ploughings and harrowings, nearly or quite the whole of the stubble will be decomposed and blended with the soil, and be rendered a valuable manure, by the reciprocal fermentation of the land and the stubble, the former being set into activity by the cultivation, the latter from its easy decompositions soon feeling the effect of the former, when they act conjointly in their general fermentative and fertilizing process.

When a crop is to be principally benefited by the manure laid on a field with one ploughing only, the manure should be rich, and in a forward state of decay, because its decay, when in a "long" state, will be unassisted by cultivation, and the affinities of the particles of the soil will be too strong in their balance to expedite the process. The manure, in this case, will require to be brought into that state of decay before it is applied, which will ensure its own fermentation afterwards without aid from cultivation. And then, like shavings or small wood to a nearly extinguished fire, a partial overthrow of the strong balance of affinities of the soil will be produced, and thus far restore its fertility. But when you manure in this way, it is at the expense of the manure itself, by the loss that necessarily ensues whilst the heap lies fermenting in the mixen, with the view of its being reduced to the requisite state of decay: which decay, or rather calcination, causes a portion of its best elements and quantity to be evolved to the winds. Again, when the manure is laid on only before the last ploughing, even if it be a fallow, and a crop then sown, the manure is found distributed in the soil more or less in lumps. The young and perhaps delicate plants must be some time before they reach the manure with their fibres, and during the interval many perish. Such is the case with young turnips, if, when their roots reach the manure, they find it in lumps or masses, instead of being blended with or diffused throughout the soil; and the plants are of course injured.

The above circumstances lead to the conclusion that, both in the garden and in the field, the best time and manner of applying vegetable and animal manures—indeed, manures of every description—is on a fallow; and to cart and spread them on the land in the autumn, winter, or spring, according to their nature and circumstances; when there will be sufficient time to mechanically mix them well with the soil, by the successive ploughings and harrowings.

The only exception that can be adduced is on stiff clayey land, which might have the coat of manure applied twice to keep it the more open; as, once at the fallow, being half the quantity; and once between, as for beans, peas, and wheat.

By the manure, or manures, being so early applied, the particles of the soil are more quickly and generally divided, therefore the sooner and better able to admit the fresh air, rain, and dews; thus favouring their decomposition and union with the soil; and co-operate with the plough most powerfully in the general increase of fermentation and pulverization. The thermometer will always denote an increase of temperature when inserted into the soil about three inches, after recent cultivation, and also after recent manuring; and when these are both combined, the rise in the instrument will be found proportionally the higher. Under these favourable circumstances, it is not to be wondered at that the long strawy manure becomes soon reduced to a short fine state, and very generally distributed by the after cultivation.

Now, when any delicate seeds are sown on a field treated as proposed, they are assisted in their infant vegetation by the increased native powers of fermentation in the early manured and well pulverized soil. Their first roots have the great advantage of the necessary food being immediately contiguous to them, and in that state of delicate suspension that the least vegetative effort of the plants is sufficient to overthrow, and in consequence such a tilth is most favourable to their unfolding, their future vigour, and their arriving perfect at maturity.

If the reasoning employed be correct, this favourable conclusion may be drawn, that the early application of vegetable, animal, and other manures to the fallow contributes in a multiplied degree to fertilizing the same, by the mechanical as well as chemical assistance they impart to the power which the soil has of combining with, and decomposing, air and water, with, at the same time, their pulverizing effects: these objects could not be gained if the manures were added only before the last ploughing. By this practice, then, the four following points are gained. First, there is considerably less loss in the manure or manures, by their fermenting in the soil, instead of in the mixen. Secondly, the soil derives more fertility by the early application of the manures than when put on late, and at no expense. Thirdly, the manures being carted on the land early, less loss ensues from evaporation, the sun then having less power. And fourthly, if any kneading should take place during the carting, there is time afterwards to get the better of the evil, by having the manure, or manures, to assist the husbandman's efforts.

The application of the same kind of manure to plants or trees that are occupiers of the soil for more than one year, as hops, the artificial and natural grasses, fruit, &c., is not always advantageous, nor do the fields prove so productive as might be expected from the pains bestowed.

The advantage of variety is, that there is greater fermentation, and therefore greater benefit from the air and rains. For the same manure acts on the soil, particularly if not aided by cultivation, like the same medicine, or the same air, upon the human system, both of which are found to lose their best effect after too long repetition. In fact, the soil as well as the body becomes saturated or neutralized. This is not the case with arable land, because of the variety of the crops, to say nothing of the cultivation, particularly of the fallow, which is the most powerful of all; and thus admits of the same kind of manure being applied with success; but a change of manures has proved advantageous.

Before the subject relating to manures is brought to a conclusion, it will be proper to observe that an excess in manuring, particularly when put on raw for the coming crop, is as injurious as when land is poor from the want of manure. For of fertility there may be named three descriptions:—Extravagant fertility, productive fertility, "apoplectic" fertility. The first is, when so early and rapid a decomposition takes place that the plants thrive too fast in their youth, and then towards harvest, when they have nearly or quite done growing, they fail to perfect their seeds. This is commonly known by the name of crops being winter or spring proud and summer poor.

On examining the stalks and ribbons, they will be found to be covered with a species of fungus, which is owing to a sudden cessation of the supply of the sap; the healthy secretions are in consequence at an end, and fermentation of the juices succeeds; a gas is then formed, which bursts the vessels, and the fungi grow.

The cause of this extravagant fertility is this: the corn was sown upon fresh or recently manured land, the land being in itself poor from previous exhaustion: the result being, that the corn receives its food directly from the manure, in the first instance, and of course in an unselected, undiluted state, instead of disengaging it from the soil, with which the particles of the manure had been lightly combined by previous good cultivation, for the fresh manure decays faster, and thus yields and indeed rather forces itself upon the plants beyond what they naturally and immediately require. And being aided in its decomposition by the vegetative powers of the corn, a too rapid growth is at first brought on. Then, as the plants had been induced to commence their structure upon a large scale, by the abundance of the materials afforded them, they require a proportioned greater quantity of the same materials to maintain and complete what they had begun; but from the twofold cause, of an early extravagance, and large structure, they find those materials deficient at the very time when wanted the most, at the forming and completing of the seed. The soil, all the time, from its poverty, or strong balance of affinities, effects but little towards the growth of the plants; therefore, out of the two sources of fertility, namely, manure and good cultivation, the one most important, meaning the latter, having been neglected, fails of its necessary supply, and disease of the plant takes place accordingly.

The cause of productive fertility is owing to a regular decomposition going forward within the reach of the roots of the growing plants, when food is yielded sufficiently fast to meet all their necessary demands, and continues thus to be yielded from the beginning to the end, so that a well matured crop is formed yielding bright straw, and a handsome plump sample, in quantity proportioned to the native fertility of the land. This favourable result is to be attributed to the crop being able to disengage its food from the particles of the soil, with which it has been combined by a previous good cultivation and exposure, or fallow process. The beneficial consequence of which is, that the plants have to exert their own decomposing and selecting energies to obtain the food they require, and therefore take up no more than what their healthy vegetation demands; instead, as in the former case, of having their vegetation impelled on, as it were, by the too rapid and overwhelming self-decomposition of the manure.

The cause of the "apoplectic" fertility is owing to a too rapid decomposition taking place throughout the growth of the plants, as is the case if a few grains of corn happen to fall upon and take root in a dung mixen. The plants are seen to flourish away with uncommon vigour, as if in a state of intoxication, producing ribbon by wholesale; if standing in masses, they are soon heated down by the winds and rain, when, the straw becoming bent, the sap is then more or less impeded in its flow through the vessels, which are already overcharged with half concocted food, forced into circulation by the too rapid decay of the manure beneath; the consequence is the bursting of some of the vessels, when a nidus is formed for the fungi species, in the form of red rust, &c.; and if this corn ever ripen, a lean half-formed grain is the only produce.—*Bland's Principles of Agriculture*. Second edition, Longman and Co.

THE EMBELLISHMENT OF GARDEN WALLS.

This is a thing that is rarely or never well done, even by the best gardeners. It is quite a neglected subject, and the general aspect of garden walls is deplorable. Now, if we cannot, among the enormous number of plants upon which we may draw, find enough handsome and really effective climbers wherewith to cover every particle of wall with beauty and interest, we certainly have very little to boast of. Walls afford the best positions for many things that do but little good in the open air without their aid; walls, if well covered and carefully attended to, are among the most useful aids to a garden. Well covered in every part with good climbers, the stiffest and most awkwardly placed of wall surfaces becomes a thing of beauty, and may afford interest and flowers at all seasons, from that of the wintry bloom of the clear yellow *Jasminum nudiflorum* to the heat of early autumn, when the fine Clematises become masses of bloom. The climate of the British isles is so much varied that plants which grow as standards in the south may require a wall in the north; in the south we may have walls covered with sweet Verhena, and even with *Pittosporum*. In the south we grow the Fig as a standard; in the north it can hardly exist with a wall. But in all parts we may make good use of every particle of flower-garden wall, no matter what its texture, aspect, or height.

The first and most important consideration in the covering of garden walls is the selection of the plants. But even where these are well selected, there is frequently a mistake made in the training, by paying no proper attention to train the tree over the wall in a spreading manner, but, on the contrary, allowing it to run "up to a head," so to speak, each plant being top-heavy, and narrow and naked at the bottom. Instead of taking one good specimen and making it cover a full portion of the wall, people plant them rather thickly, and then keep continually clipping away the luxuriant shoots that ought to widely furnish the wall. The best shoots should be taken out in a fan-like manner, so as to cover the wall to the very ground. In training them out, in fact, the strongest shoots should be taken to the right and left, perhaps to send up straight shoots themselves. The object should be to keep every part of the wall covered, the centre of the tree as much so as the top of the wall, and in fact all parts equally. When once the trainer is impressed with the desirability of covering the wall equally in all its parts, he will have no difficulty in doing so. A great point is to make the strong-growing kinds cover a great deal of surface. Confine them to a small space, and you must cut them away fortnightly, or allow them to run disgracefully wild.

Now for the selection. A great many things are named in lists of wall

plants, &c., which while doing very well in such positions, rarely flower or exhibit any beauty. We must name a few more of these than we desire, in case some people should be disappointed at their omission; and, besides, they may now and then be found to have their special uses. But to make the selection more useful we will place an asterisk before the names of all such as are A I for ordinary purposes, and worthy of general recommendation. We must place the *Irish ivy at the head of all evergreen climbers. The rich sheets of verdure it produces are not to be equalled by those of any other plant that grows with us. The varieties of the common ivy are so numerous and beautiful, that little space can be afforded for the old forms in the garden proper; but few can resist the charms of the variegated varieties, and *Hedera Regneriana. *Cotoneaster Simmondsii will prove a rapid-growing fine thing for high walls and large rockworks. Bignonia capreolata and Tecoma radicans are both good for walls with good aspects in the warmer parts of the country. *Passiflora cærulea will not do much in the colder parts, but generally will be found to thrive on a warm wall. A house sprinkled over with its showy fruit in autumn looks very striking. *Chimonanthus fragrans. *Virginian creeper—things of this kind, that grow freely upon bowers and over old trees, &c., should be, generally speaking, reserved for such places, as the wall space will be little enough for the plants that really require its beat and assistance. *Wisteria sinensis and alba. The Weigelias are of course fit for low walls, and very pretty; *Magnolia grandiflora and its varieties, particularly the Exmouth one; *Jasminum officinale and *nudiflorum. The Escallonias—these do very well in Ireland in mild parts. *Cratægus pyracantha, Clematis atrovioleacea, C. azurea grandiflora, *C. flammula, C. florida, C. florida pleno, C. Sieboldii (bicolor), C. Fortunii, C. Guaecoi, C. Hendersonii, *C. Jackmanni, *C. lanuginosa, C. lanuginosa pallida, C. montana, C. regina, C. rubra-violeacea, C. Standishii, C. tuberosa, C. viticella, C. viticella venosa. The new large-flowered Clematises, in the way of C. Jackmanni, are noble in size and beautiful in colour. They may be well grown upon a wall, are fond of a light, deep, and sandy soil, and like to have the surface mulched. *Cænothus azureus thyrsofolius, C. azureus grandiflorus, C. dentatus, C. floribundus, C. Lobbianus, *C. papillosus, and C. velutinus. The Cænothuses do very well in the warmer parts, and in the west, though they are liable to be cut off occasionally by hard frosts. The Tea Roses. These are the most beautiful of all things for covering dwarf walls with good aspects, such as frequently occur in terraced and other gardens; and occasionally other kinds, such as Banksian, will be found highly suitable for walls. Strong climbing kinds should not be placed on the select walls, but on rough banks, &c. Periploca græca. Lycium europæum, good for high and rough walls; fruit bright red. *Lonicera japonica. *Abutilon pitifolium—this is a good plant, not at all sufficiently known for this purpose, but fine; may prove a little too tender for some parts, but a capital thing for the milder localities; will require a good stretch of wall. As for fugacious annual things for walls, it is better to avoid them. All such stuff is better trained on low trellises, as by so doing we avoid the trouble of nailing them; they turn round the wires and take care of themselves. The great *Rubus biflorus, with the apparently white-washed stems, grows freely in the open air with us; in many parts the shelter of a wall has proved acceptable. The Camellia may be grown as a wall plant in warm and genial parts of Britain, and even the Tea plant lives with a good aspect and light warm soil. The sweet Verbena, so grateful to many, is best grown against a wall, even in those parts where it does not survive the winter. Finally, we lately came upon one of the most beautiful greenhouse plants in existence—the sweet-scented Rhyncospermum jasminoides—flowering beautifully against a low wall. It had resisted the late severe frosts, and was planted in a nice little bed of sandy peat—the same stuff it enjoys when under pot-cultivation.—*The Field.*

NEW HARDY SHRUBS.

The following recently introduced shrubs, which have been proved capable of withstanding the winters in most parts of Great Britain, are all highly interesting acquisitions to our stock of hardy evergreens, and deserving of general cultivation:—

Euonymus radicans variegatus.—This pretty dwarf and compact growing plant has stood the past four winters with us without sustaining the least injury, although in the protracted storm of last January the minimum temperature was one night as low as 11° Fahr., and on several occasions under 15°. The constancy and beauty of its silvery white variegation, which is occasionally tinged with pink, makes it highly suitable for ribbon lines and edgings; and the free rooting property from which it derives its name renders it of the easiest propagation, as its branches even put forth an abundance of roots above ground, where the plants are grown in a close, warm, moist atmosphere. Our four-year-out plant is not yet more than nine inches high, although house-grown specimens of the same age are about twice that height; and for foliage effect it stands in favourable comparison with the silver-edged geraniums, hence it will be found especially useful for amateurs and others who may have no means for wintering these universal favourites. We observe that the successors of the late Dr. Von Siebold are sending out from their celebrated Leyden nursery the original or green form of this plant, which is expected to be still more hardy, and if of the same compact habit of growth it will also be an excellent plant for edgings, &c.

Aralia Sieboldii has stood out the last three winters alongside of the lays, and although its leaves, or rather leaf-stems, were bent down and slightly injured by the snow and frost of last January, the plant is now putting forth a full complement of new shoots and enlarged foliage. Mr. Fortune states that in northern Japan this species is a handsome evergreen bushy shrub, from twelve to fifteen feet in height; and its fine glossy foliage, which, when viewed at a short distance, may be compared in size and appearance to that of the horse-chestnut, will form quite a novel feature among that of other hardy evergreens.

Grisebina littoralis.—This beautiful, glossy, broad-leaved evergreen, which sometimes grows in New Zealand to the height of sixty feet, was not in the least affected by the 11° of minimum temperature last January, which cut down the common *Laurustinus* and injured the shoots of the common bay laurel, as well as those of the sweet bay, that were growing in its vicinity, so that it may be considered one of the showiest of hardy evergreens.—R. M. S. in "The Farmer."

■ *Grisebina littoralis* always suffers severely near London in hard winters, and has been frequently destroyed at Stoke Newington, notably so in the winter of 1860-61. In the nursery of Mr. Drummond, Bath, it is not hurt in winter, and it flowers freely, and bears abundance of berries.—Ed. G. M.]

THE ELDER TREE.

The common elder (*Sambucus nigra*) is so decidedly a household plant that any attempt to describe it would be useless. Its name *Sambucus* is said to be derived from *Sambuca*, a musical instrument made of it. I can well believe this; for, in my boyhood days, its hollow stems were the unconverted timber out of which our whistles and pop-guns were made, and so like that of the box that foot-rules are made of it. In Scotland it is called the bower tree, pronounced "boor tree," as in the old ballad—

"What care I for howlet's cry,
For boor-tree bank or warlock craigie?"

But in the Scottish ballad of the courtship of that doughty wight the "Laird of Cockpen," we find the name of elder—

"Lady Jane she was making the elder-flower wine."

I have tasted the elder-flower wine, but can say very little in its favour; but elder-berry wine is certainly a very agreeable beverage when warmed and spiced. The elder is a rapid grower at first, and survives for a long time as a stunted bush or low tree, with a thick shady top; and, being a free flowering plant, it is generally covered with blossom in summer, and heavily laden with berries in autumn. It is a coarse feeder, and thrives best where there is plenty of moisture: indeed, such a plant must have a good supply of raw materials at hand, as it will rush into such a rapidity of growth as is scarcely known among woody plants, frequently producing a crop of strong shoots six feet long in a season, when once it gets established; and it does not take a long time to get that: only let it be planted in season time—November, December, or January, not later—and no failure need be apprehended. When the elder begins to grow, if one did not know its character and history, it would easily be taken for an herbaceous plant; and its stinking foliage and blackish green colour would father it upon the worst form of umbelliferae, and, if not poisonous, at least so ill-favoured and uninviting that no one could think of eating any part of such a plant, unless he had got sound information beforehand on the subject. But although the elder has the lurid poisonous look and the hollow stem of the hemlock brood, it is not an umbelliferous plant, but belongs to the honeysuckle tribe (caprifoliacea); and although its stem be hollow, it is, after all, both woody and perennial, forming one of those marvellous links which we frequently find in botany, uniting opposite characters. Had the elder been blessed with foliage as sweet as that of the walnut-tree, it would not have been half so valuable to the farmer; for it is very rarely indeed that you see the elder tree touched by hares or rabbits. During long and severe frosts, with snow, I have seen sticks of all kinds bitten, and branches that had been cut off where trees had been felled would be barked as clean as if the woodman had stripped them for the tanner. But, as a rule, hares and rabbits do not bark the elder; and as for the leaves, the smell is quite sufficient to warn either cattle or coney from laying a tooth upon them.

This style of plant is called by planters a "nurse," and they put in such by millions to shelter better trees.

Since the system of bedding out greenhouse plants for the flower garden in summer became a common practice, everybody has become aware that such plants as the geranium and verberna are increased by cuttings of the green wood, with more or less of the leaves attached. Now, although the elder is to be increased by cuttings, it being a deciduous tree, it is not to be treated in this manner, and it is not to be propagated in summer, or when growing, as is the case with geraniums, &c. The elder, the willow, the gooseberry, and the vine are mostly propagated by truncheons of the stem of the wood of the current year, taken off the parent plant when the sap is down, or when the leaves have fallen, and the plant is in a dormant state. The truncheons of the elder may be one or two feet long, and ought to have one joint in the earth when planted, and one or more out; the truncheons should be cut below a joint with a clean cross cut, not slanting; the truncheons to be planted at once where they are to remain, and should be not less than four and a half inches deep in the ground, firmly planted in finely pulverized soil. It may not be desirable for many reasons to purchase costly trees, and plant them at one's own expense upon other people's land, and yet the use and shelter of trees must be had; for stone walls, even if these could be had, are not to compare with trees in breaking the force of the wind, for the walls produce eddies and often whirl the wind with great violence against particular points, but trees sift the wind and never gather it. A farm standing unsheltered by trees ought to be a terror to an incoming tenant, as it ever will be to those who have to do battle with the storm in such a place thus miserably left to its mercy. When our ports and harbours were swept by wind and tide, the breakers seriously interfered with our shipping interests, and we had to erect costly breakwaters, behind which the stately craft could ride at anchor unmolested by the storm. This was sterling wisdom and forethought, well founded upon dearly bought experience; therefore, let no one think lightly of masses of cheaply got trees to adorn the landscape and shelter man and beast. But I have another object in view with branches of trees on the farm; for faggot wood is calculated to do a species of work that no other material can do so well. In the kindling of fires, the heating of bread ovens, and in various other ways, the faggot stack is essential to the work; but on a clay farm the faggot wood, in immense bulk, is particularly wanted to huru the clay with; for there is no other process at all to compare with burning to bring the clay into good working order, for it is chemically changed as well as mechanically when it has passed through the fire; and for want of fuel of the right kind it never could be done. It is only such materials as Pharaoh used in his brick croft that the farmer can use in burning clay—such as stubble and straw of all kinds, and particularly bean straw and wood faggots; for coal, however cheap, is no fuel for farmers to burn ridges of wet clay with. There are only two ways in which elder trees appear to me to be in character, and these are circles and lines. No figure equals the circle, for it has the same front on all sides, and the general appearance is that of one vast bush. It is no waste of land to sacrifice so much for the sake of shelter. Planted in lines as hedgerows, the elder will be quite established in two years, and form a fence; planted against a low stone wall, hurdles, pales, &c., it forms an excellent fence by adding one story to make up for the deficiency of the wall; and, as it never grows large, it does not rob the land like timber trees. I remember a hedge made of elder shoots to screen a garden; it was about 100 feet long, and one man cut the shoots from the bushes, carried them on his back half a mile, cut them into lengths, and planted them, without any further cost than his own labour, and that was for half a day! Cottagers and tenants-at-will should take a lesson from this experiment; for it was a tall strong hedge in two years, and such a wind-guard would be no small benefit to those who rear calves and poultry, and, if they made no use of the elder berries, the fowls would eat them greedily.—ALEX. FORSYTH, in "Mark Lane Express."

BEDDING GERANIUMS.—No. XLIV.

I intended to reserve for No. L., as a sort of "golden number," and in imitation of the German custom of celebrating a "golden wedding," the bright story it is now my hap to tell. I am on the top of a mountain in one of the extremest corners of Britain, where geraniums are *non est*, and heather in bloom makes a very bearable substitute. In such a case, I cannot well discuss the merits of varieties, for I have not got them all so completely in my head as to be sure I should make no mistake in comparisons and values. Moreover, as I look around the landscape, and feel convinced that I am but an atom of insignificant dust in the midst of the vast hills that roll around me, and that tower up higher and higher towards the horizon in misty indigo outlines, I could more reasonably speak of the splendour of a wild poppy that has made itself a home in this wild place, than attempt the characterization of things that, from my present point of view, appear so trifling that I almost wonder I ever gave them an hour's thought at all. For the atom of dust sitting here upon the top of the world, where the clouds come down and kiss the ground, it is enough to know that heaven and earth are not parted far asunder, and the beginnings of things are not wholly hidden. Here I see the birth of many a sparkling burn that leaps innocently from rock to rock, gaining strength as it begins to swell to a river, to expand into a sea, to bathe and bless the world with the great watery girdle, wherein are sown the seeds "of continents to be." From this spot, where I am more deeply impressed with the majesty and oneness of nature than with any of her minor beauties, I can speculate on the beginnings and ends of things; and I ask, what would be the result in ten years of turning loose in the land they came from all our thousands of named varieties? The result would be, no doubt, that a few of the most robust varieties, and those especially that are powerful in pollen, would overcome and extinguish all the rest; and if the mixed race did not actually revert to the wild type out of which it sprang, it is pretty certain that the nice shades and distinctions that occasion us so much discussion would be quickly extirpated, and that a few amongst thousands of characters would take the lead. It is the question of questions for large and small, and in respect of large and small; the mammoth had a beginning *and* an end! The bright runnels that tumble down the chasms from this top of the world begin in the cloud-mist that settles on the mountain broom and ling, and they end in the "great immensity" of the billowy sea. This atom, certainly its most dusty, had a beginning, and will have an end. The universe is like a clock, with every beat of which a new world is born as another dies. The study of races, and the arts that spring out of that study, or derive light from it, must be earnestly pursued by any who are truly curious about the origins of organic forms; and if we can trace the progress of the metamorphosis by which any one form is transmitted to another, we shall obtain one more clue to the explanation of the mystery of life. I am not ashamed, therefore, of the subject before me in the presence of the brown herbage, and the crimson slopes, and the indigo undulations far away; for every herb that labours to convert a stone into a cushion, and a grim dyke into a rosy dimple on the face of the earth—every such wilding has a history that goes far back into the unrecorded ages; and what we call, perhaps, a *Lychnis* or a *Silene* now were other than *Lychnis* or *Silene* in the birth of time. In the case of pelargoniums, we may reasonably believe that some of the types that have become established by man's interference, would continue if the whole of them were consigned to the wilderness. What we have done nature probably would do, for we must suppose that *all possible* variations will be brought about in time; for nature has choice of all necessary materials, and is in no fever of haste; and all we can hope from experiment is, first, the gratification of curiosity, and, second, the obtaining of a key to the order of procedure that prevails throughout the world.

I happen to find, amongst the few papers that I brought with me to the hills, a careful record of a system of experiments followed out by my excellent friend and neighbour, Dr. Denny, of Stoke Newington. The doctor agreed with me long ago, and we have scarcely altered our opinion to this day, that published pedigrees of geraniums were, as a rule, valueless. In some cases the writers were sincere, but deluded. In other cases the writers had made "shrewd guesses" in the first instance, relying on family likenesses, and the guesses were elaborated into theories, and the theories were pronounced in persuasive language, and the world was thereby taught what no living man actually knew; it was fed with fiction under the name of fact. Having agreed that there were many delusions abroad, and that published pedigrees were, as a rule, valueless, the question arose, how and by whom shall the matter be put to the test of experiment? The doctor resolved to practise cross-breeding in a systematic manner, and to keep a record of everything done, and secure—what perhaps was never done before—the complete history of every individual seed. The experiment has proceeded far enough to render reticence no longer

needed, and I shall now gather together all the points that appear capable of furnishing interest and instruction.

During the summer of 1866 Dr. Denny practised artificial fertilization with a selection of varieties of zonals. A note was made of every flower operated on, and every seed-pod was marked; and from first to last the utmost care was taken to preserve the links of relation between the seeds and the plants resulting from them, with their several parents. The seeds ripened in 1866 were sown on the 28th of April, 1867. They represented all known breeds and strains, and as the most noted typical varieties were chosen to seed from, the growth of the seedlings afforded an entertainment that well repaid the labour involved in their production. All the seedling plants that remain (very many died in the first stage of existence) are in a fair condition for judging them as to the significance in this connexion of the word "blood." We have nothing at present to do with their merits *as varieties*, all that really interests us is their likeness or unlikeness to their parents, their relative degrees of colour, size, form, strength as compared with their progenitors, their degrees of departure from the types to which, by genesis, they are directly related. We want to know what is the power of blood; what is the meaning of "race"; and how to select parents when a special kind of progeny is our desire. Shakspeare would have entered into this question as heartily as any. The question of race and the influence of blood must often have occupied his thoughts, for sentiments on the subject are many times the life of his noblest passages. Ask the Bastard, or call to mind that early song—

"From fairest creatures we desire increase,
That thereby Beauty's rose might never die."

In the list now compiled from Dr. Denny's stud-book, I shall employ such terms as are required by the classification proposed in No. XL. In this classification "gold zonal" is the equivalent of "golden tricolor," and "silver zonal" is the equivalent of "silver tricolor," &c., &c., &c., &c., &c. In case the reader is not now familiar with the scheme, it would be well to read No. XL before proceeding any further with this.

1.—*Seed parent*, Mrs. Pollock; *Pollen parent*, United Italy. A few only of the seeds germinated, the cotyledons were quite white, and they all quickly perished.

2.—*S.*, Madame Vaucher; *P.*, United Italy. Four plants were raised, all of which are now alive. They comprise, 1 robust zonal with dark zone, now breaking into a variegated form, having one complete and well developed pure white leaf: 1 medium strong zonal with a few white breaks: 1 neat but small zonal: 1 small sickly plant, the leaves quite white, with delicate pink zones.

3.—*S.*, Stella; *P.*, United Italy. One plant was raised, which is now alive; it is a very neat compact zonal.

4.—*S.*, Monsieur Barré; *P.*, United Italy. Four plants were raised, all are now alive; they are all neat zonals, and there is not on any one of their leaves a single break visible.

5.—*S.*, Wonderful; *P.*, United Italy. Seventeen plants were raised, sixteen of which are now alive; they comprise 12 zonals, all neat, and varying in depth of zone and size of leaf: 2 silver zonals, diminutive and sickly: 1 deeply zoned, and freely breaking into white variegation: 1 intermediate between a zonal and a bronze zonal, and promising to become soon fixed in the bronze class.

6.—*S.*, United Italy; *P.*, Mrs. Pollock. The seed saved appeared to be good, and several plants were raised. They all came up with white cotyledons, and all quickly perished.

7.—*S.*, Cloth-of-Gold; *P.*, Mrs. Pollock. Out of many seeds only one germinated, and that is a zonal, with leaves zoned in precisely the same degree as Reidii.

8.—*S.*, Stella; *P.*, Mrs. Pollock. Six plants, comprising 2 neat and complete zonals: 2 zonals, breaking and promising well; one of these shows a pink zone on a white ground, in another there is a pure white leaf, the other leaves being in the style of Commander: 2 diminutive and decidedly variegated.

9.—*S.*, Burning Bush; *P.*, Mrs. Pollock. Several plants were got up, but all had white cotyledons, and all died early.

10.—*S.*, Countess of Warwick; *P.*, Mrs. Pollock. All came up white, and all died.

11.—*S.*, Beaton's Lady Callum (nosegay); *P.*, Mrs. Pollock. Out of several seeds only one germinated. The plant is a mite, with leaves mixed yellow and green.

12.—*S.*, Madame Vaucher; *P.*, Mrs. Pollock. Thirteen plants in all, one of which died; a very interesting lot. 4 neat zonals, one of them breaking into deep red zone and a few radial bars of cream colour: 3 finely broken into gold zonals, the margins canary-yellow, the zones bright red: 1 breaking into a pale gold zonal: 3 breaking variously and diminutive in size: 1 pretty bronze zonal.

13.—*S.*, Wonderful; *P.*, Mrs. Pollock. A large amount of seed of this cross was obtained. There are forty-six plants alive, three have died, many of the seeds refused to germinate. 18 neat zonals: 5 decided gold zonals, one of which is very promising: 8 breaking into gold zonals: 7 breaking into silver zonals: 8 so undecided that they may be said to show traces of the characters of all the classes.

14.—*S.*, Rose Rendater; *P.*, Mrs. Pollock. Fifteen plants in all; 7 decided and beautiful zonals: 2 curiously marbled, and showing radial bars of white, yellow, and red: 2 robust zonals breaking into gold zonals: 2 weak zonals breaking into gold zonals: 2 fine plants in the first stage of breaking, showing a few patches and bars of yellow.

15.—*S.*, Mrs. Pollock; *P.*, Burning Bush. A dozen plants were obtained, some with white, others with cream-coloured cotyledons; all died.

16.—*S.*, Stella; *P.*, Burning Bush. Only one plant was obtained; this is small but healthy, the leaves about half dark zoned and half silver zonal.

17.—S., Beaton's Lady Cullum (nosegay); P., Burning Bush. Two plants obtained; 1 a nice zonal: 1 very small, freely breaking into a silver zonal.

18.—S., Madame Vaucher; P., Burning Bush. Four plants; 3 robust zonals: 1 with leaves wholly white, leaves half zoned and half white, and white with pink zones.

19.—S., Countess of Warwick; P., Burning Bush. Two plants; 1 a neat strong plant, the leaves exactly divided by the line of the mid-rib into one half zonal, the other half white with carmine zone: 1 diminutive and slightly breaking into silver zonal.

20.—S., Monsieur Barré; P., Burning Bush. Seven plants; 4 strong zonals: 1 small zonal: 1 small half break silver zonal: 1 mite almost wholly white.

21.—S., Monsieur Barré; P., Mrs. Pollock. Twenty-one plants; 9 neat and healthy zonals: 3 diminutive zonals: 1 fine break into gold zonal: 1 with one fine leaf of gold zonal, the rest zonal; 5 with traces of yellow breaks.

22.—S., Beaton's Lady Cullum; P., Countess of Warwick. Only one plant raised, and that a neat dark zonal.

23.—S., Madame Vaucher; P., Countess of Warwick. Three plants; 1 a very strong and handsome zonal: 1 a small neat half zonal and half gold zonal: 1 variegated and very pretty.

24.—S., Monsieur Barré; P., Countess of Warwick. Four plants; 1 zonal, and the best of the whole batch, the leaf flat and round, zone broad: this had variegated cotyledons: 3 neat healthy zonals.

25.—S., Wonderful; P., Countess of Warwick. Nine plants, six of which are living; 3 made leaves wholly white, and died: 3 are neat healthy zonals: 3 diminutive silver zonals.

26.—S., Wonderful; P., Burning Bush. Only one plant, and that a mean little zonal with dark zone, showing a slight silvery break.

27.—S., Countess of Warwick; P., Stella. One coarse zonal.

28.—S., Mrs. Pollock; P., Wonderful. The plants produced yellow cotyledons, and all died.

29.—S., Countess of Warwick; P., Cloth-of-Gold. Several came up, but only one lived, and that is a good bronze zonal; the disk and margin combined orange and sulphur, with trace of green, zone obscure cinnamon. A fine seedling.

30.—S., Mrs. Pollock; P., Monsieur Barré. Seed did not germinate.

31.—S., United Italy; P., Wonderful. Two seeds germinated; the plants grew till they had six leaves each, wholly white with pink zone; at that stage they perished.

32.—S., Monsieur Barré; P., Alma. Seed did not germinate.

33.—S., Madame Vaucher; P., Alma. Two plants; both commonplace zonals, of no interest at present.

34.—S., Mrs. Pollock; P., Rose Rendatler. Six plants; 4 pretty zonals: 2 breaking finely into gold zonals, the colours brilliant, plants healthy and vigorous. The result of this cross nearly the same as No. 14, in which the parents are the same, but the sexes are reversed.

35.—S., Monsieur Barré; P., Mrs. Pollock or United Italy. Twelve plants; 8 pretty zonals: 1 a remarkable plant with some leaves healthy dark green zonal, others wholly white with no trace of a zone: 1 breaking into a gold zonal: 1 a diminutive gold zonal: 1 a silver zonal. The doubt about the male parent in this cross is a matter of regret, seeing how various in character are the progeny.

36.—S., Wonderful; P., Mrs. Pollock. Four plants; 2 common zonal: 2 breaking finely into gold zonals and showing much rich orange colour in the margins.

37.—S., Madame Vaucher; P., Mrs. Pollock. A few seeds germinated, producing white cotyledons, and quickly perished.

38.—S., Madame Vaucher; P., Mrs. Pollock. Fourteen plants; 8 good zonals: 3 pretty breaks into gold zonals: 1 bright and good silver zonal: 2 extremely poor silver zonals.

It will be observed that the results, so far, are of a definite kind. We shall have to watch the plants through further phases of their growth, and especially to take note of the colours of their flowers. But for the present we see that the characters of the parents are in a great part immediately transmitted, but not wholly or invariably so, for in many instances there is a tendency to revert back to the common zonal form. Another evident result is that it is of little use to breed from two highly variegated kinds; one of the parents should be a zonal of good constitution. In the case before us Monsieur Parré, Rose Rendatler, and Madame Vaucher, all of them zonals of vigorous habit, prove to be good parents, and the pollen of variegated kinds communicates to the progeny more or less of colour. On the other hand, Wonderful, which is a zonal in the way of Commander-in-chief and Beaton's Lady Cullum, gave poor results under several crossings with the pollen of variegated kinds. It will be observed too, as in Nos. 1, 6, 7, 9, 10, 15, 19, 31, 37, that breeding from two variegated kinds affords a very poor prospect of obtaining plants, yet would appear to afford the hope that if well selected a valuable seedling may be occasionally produced, as in this particular cross the resultant plant is beautiful, and possesses apparently a good constitution. Another lesson to be learnt from this experiment is that it is of no consequence whether the male or the female be zonal or variegated. A comparison of 13, 14, and 34 will show that it is not essential the zoned parent should be either the male or the female; that if the parents be well selected, and one of them is a vigorous-habited zonal, they may be crossed both ways, that is to say, both may be made to supply pollen and both to supply seeds. In a paltry, stupid, little book by one Thomas Dixon, gardener to W. Blinkhorn, Esq., of St. Helen's, which any of our readers who like to waste their money can obtain from Mr. Lees, stationer, of St. Helen's, the law is laid down that "the zonal variety must be used for the male parent, and will in most cases make the best male parent. As regards the female parent, it may be a variegated sport, or selected from the Tricolor hybrids already in existence, according to the object in view." If there is anything at all in Dr. Denny's

work to make us incline one way or the other, we should be compelled to favour the selection of the zonal for the female, and the tricolor for the male, and this would be in exact accordance with the long-established and founded-on-experience rule of the florists, to select for the mother a plant characterized by *good form*, and for the father one characterized chiefly by *good colour*. You will find this in the books, and so far the books are right. This Thomas Dixon has probably never raised a tricolor in his life, but if he had possessed enough sagacity to frame an imaginary scheme of breeding worth a moment's attention, he would have gone to the books and have obtained at least *this* hint towards his project. If this book had not been recommended in one of the horticultural journals lately, I should let it pass unnoticed; but there are so many amateurs engaged in breeding tricolors, that it becomes a duty to sweep from their path all obstacles, and chimeras, and ignorant guides. Let Thomas Dixon learn what is meant by the term "hybrid" ere he again ventures to play at philosopher in respect of them. It is a point of some interest in the case before us that none of the thirty-eight crosses, yielding a progeny two hundred-and-four in number, have produced a single example of plain green leaves, such as would be classed with Tom Thumb in the first section of my system. *Pelargonium inquinans* and *Pelargonium zonale* will breed together, but they are not commutable forms, and neither will of itself produce the other.

More deaths occurred than are recorded in the foregoing report, but Dr. Denny took note of the deaths as to their manner, though rather careless as to their number. When the cotyledons were quite white, death occurred invariably. When the cotyledons were partially variegated, there was a better prospect; and though some deaths occurred amongst these, a large proportion became ultimately vigorous plants. In nearly every case where one of the parents was a plant with variegated leaves, whether white, creamy, or golden, the cotyledons were more or less coloured. But a large proportion of these became definite zonals; some made a few yellowish or whitish leaves, and then started away and became definite zonals; and some were variegated in every stage of their growth from the cotyledons forward. In several instances Dr. Denny compelled the plant to a green growth when the leaves were wholly white, by carefully cutting away one side of it—a delicate operation with a plant less than an inch high, and with leaves the size of a threepenny-piece. Those operated on in this way put out shoots from the side left, and amongst these there usually occurred one with some amount of green, which took the lead and made a plant. Of course it is expected that all the zonals that had variegated cotyledons, and especially those that presented a few variegated leaves in their first stage, will ultimately break, for this is the common experience of the breeders of tricolors. Let us hope that Dr. Denny may be rewarded for his labour by finding amongst his plants some worth a name and a place in history. But whether this occur or not, he will assuredly find some reward in the conviction that he has been enabled to throw much light upon an obscure problem in vegetable physiology, and it is for other practitioners in plant-breeding to take advantage of the facts now communicated.

S. H.

PROFESSOR BALFOUR ON WINDOW FLOWER EXHIBITIONS.

The third annual exhibition of flowers and plants grown by the working-classes of Edinburgh, in windows, back-greens, areas, and city garden plots, was held in the Grassmarket Corn Exchange, Edinburgh, on Saturday, the 3rd inst., when the products sent in for competition presented such a marked improvement and increase in numbers over those of the two preceding years as should induce not only the promoters of this philanthropic movement to go on perseveringly in extending a taste for flowers and flower culture among the artisans of the Scottish capital and their children, but to show an example well worthy of imitation in other towns by those who have the means of fostering a love for the instructive, humanizing, and elevating pastime of flower-growing among their less opulent neighbours.

Before distributing the numerous awards, the chairman, Dr. Balfour, professor of botany, said he had to congratulate the meeting on this most successful show. The committee had examined the articles sent in for competition, and they had unanimously declared it to be one of the best shows they had seen. This year they had about 100 more competitors than last. The improvement in the keeping of window gardens and areas was quite remarkable. He was delighted to see the working-classes taking so much interest in plants. It was natural to man to do so. His existence as a worker began in the garden; whether in health or sickness, flowers and plants afforded him a solace and delight. He believed the culture of flowers had a most humanizing influence, and even in the most crowded parts of the city they would spring up; and where they were carefully tended they could not fail to have an excellent effect on the temper, conduct, and life of those who bestowed on them their care. He hailed this as a most auspicious occasion, and he was delighted to see that the whole collection was remarkably good. Some of the plants here, even those cultivated by juveniles, were equal to what they would find in the Botanic Garden. The collection of John Hestline, embracing 200 plants, well grown, delicate in form, and rich in colour, was really wonderful. The window frames were admirable, great taste being shown in the contrast of colour and in the training of the plants. The committee appointed to visit the areas reported that they were this year greatly improved all owing to this movement.

JONES'S TERMINAL BOILER.

In consequence of a remark on the peculiarities and advantages of this boiler in one of Mr. Prosper's papers, inquiries have come to hand for further information. It has several peculiarities. In general plan it is a saddle; but, instead of the fire passing through the furnace at the end opposite the furnace door, and thence direct into the flue, that end is blocked up, and the products of combustion are turned aside right and left under the two wings of the boiler, which, when the boiler is properly set, form the tops of the side-flues. They next pass over the front part of the boiler to the top, where they escape into an upright shaft. The boiler in its most simple form is represented in fig. 1, where it will be observed that the wings form an integral part of it, and that the furnace

Fig. 1.

bars, which are hollow, are connected with the return of the water to the boiler. The object of these peculiar arrangements is to economise to the utmost possible the heat arising from the combustion of the fuel. As much heat must escape to the flue as suffices to cause a proper draught in every kind of furnace, or there can be no combustion; but whatever heat in excess of that requirement goes away to the flue is the product of wasted fuel. In the majority of furnaces, of every description and for every purpose, there is immense waste of this kind. In the case before us, one of the most decisive improvements for the saving of fuel is the closing of the arch. Instead of the flame rushing out and wasting its heat upon the brickwork, as in the common form of arch-boiler, it first beats upon the terminal plate which closes the arch at the end, and which

Fig. 2.

forms the end of the boiler, and its energies are therefore expended on the circulating water, to the immediate advantage of the person who has to pay for the fuel. Another advantage is gained by the play of the flame on the wings; and, after this twofold service in excess of what is derived from the fuel in ordinary furnaces, the flame and smoke are allowed to escape. The fire-bars are hollow, and form part of the return system, which may be some advantage. We confess, however, that we do not attach much importance to hollow bars, and would almost as soon be without them as with them, as ordinarily constructed. But the terminal arch and the side-wings are valuable extensions of the heating surface, and give this boiler a pre-eminence for economy and power, which fully entitles it to the distinctions it has obtained of late amongst jurors at exhibitions, and practical plant cultivators everywhere.

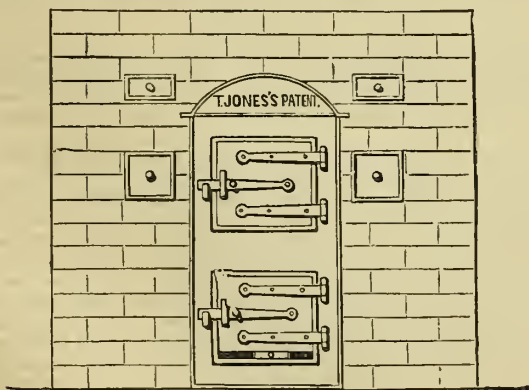

Fig. 3.

At Mr. B. S. Williams's new nursery, at Holloway, there are several of these boilers at work. One of them heats the great conservatory, the palm-stove, and the intermediate house that connects these two, in the most satisfactory manner. This is a three-feet boiler, and the extent of pipes it serves amounts to near upon a thousand feet in all. The mode of setting is shown in figs. 2 and 3. Cleaning can be accomplished by means of the soot-doors with great facility, and the fire can be checked if needful by an ingenious but simple arrangement, by which the draught is regulated. The course of the circulation is shown by arrows in fig. 2.

THE EXTENSION SYSTEM OF CULTIVATING THE VINE.

In an article published in this work on the 22nd of December, 1866, we broached the subject, which has been so warmly discussed, of the respective merits of the restrictive and extension systems of Grape-vine cultivation. In the fifth edition of Mr. William Thomson's admirable treatise "On the Cultivation of the Grape-Vine," just published, he thus expresses himself on the subject:—

While I am preparing the fifth edition of this work for the press, a keen controversy is being carried on in the horticultural journals as to the merits of what is designated the "extension system" of vine-culture, as compared with the "restrictive system," one section of writers maintaining that the proper mode of cultivation, where long-continued vigour and fruitfulness are desired, is to allow one vine to develop and extend till it has filled the house with bearing-wood. Another section as confidently maintain that vines can be kept in perfect health and vigour sufficiently long for all practical purposes on the "restrictive system" of culture—meaning by that a system which only supposes one or two bearing-ropes to be trained from each vine, and where the method of pruning is what is called the close-cutting system, where the new wood is all cut back to one eye at the base of each lateral. Thus a question of such importance is raised that I do not feel justified in passing it by, apart from which I have been asked my opinion of the merits of the two systems by numerous correspondents. These circumstances combined have determined me to devote a chapter to discussing the subject, believing, as I do, that there is much truth in what is said by the advocates of both sides of the question, as there generally is when sensible men discuss questions of this character. I may here remark that the question is by no means a new one to me; more than twenty years ago I frequently discussed it with the late Mr. Peter Kay, of Finchley. Theoretically, it must at once be admitted that the one-vine or "extension" system stands on vantage-ground. No one can deny that a tree which is largely developed, with its roots ranging over what I may term an extensive pasture field, is likely to maintain its health and vigour for a much greater length of time than one that is by the force of circumstances restricted in its growth. But there are practical difficulties in the way of the general adoption of the former mode of culture. In the first place, all experience goes to prove that the vine is what may be termed a rambling roofer. If the border is not carefully made, and of such materials as to induce the formation of a numerous progeny of fine branching fibry roots, the width of any ordinary vine-border will soon be traversed by them. This takes place even when the "restrictive system" is adopted, and it will take place with infinitely greater rapidity under the other. To meet this difficulty the roots have been walled in; but this only aggravates the evil, for the moment the roots touch the wall, they descend to the bottom of the border, where they are far from the genial influences of heat and air.

Another objection brought against this system is, that one vine takes much longer to furnish a house with fruit than a number do; but this can be met by planting supernumeraries, to be removed as the permanent one advances.

A third objection is, that variety of grapes is desirable in a vinery, and that this cannot be had where only one vine is grown. Grafting or inarching will meet this objection; and it is well known that many delicate sorts of vines grow better on other than their own roots.

Thus it appears that the only serious objection to the one-vine system is the difficulty of getting a border of sufficient scope for the roots of a vine of such proportions as will fill a good-sized vinery with fruit-bearing wood; but where such can be had, I fully approve of the "extension system," and will now proceed to give a detailed account of one of the best and most successful examples of it known to me, and with the origin of which I had some connexion.

In the year 1838 I became acquainted with the late Mr. Peter Kay, of Finchley, near London, and up to the date of his melancholy death I continued to discuss with him, verbally and by letter, every question that bore on the culture of the vine. He always maintained the great importance of what he called "carrying a large amount of foliage in the vine" as the only sure way of keeping up its stamina, and acted on this himself. I used to reply, that practically it was not expedient to allow more than two leaves to grow beyond the bunch. This, with the sub-laterals stopped at one leaf, I considered sufficient, and pointed to the example of the houses at Oakhill, near Barnet, then and for twenty years so ably managed by Mr. Davis, who produced splendid crops of grapes, ripe in March and April, for many years in succession from the same vines, and which he pruned to one eye, and left only one leaf beyond the bunch. I thought the system I adopted, of leaving two leaves, sufficient; Mr. Kay thought otherwise, and left from four to five. Carrying his ideas still farther, he said he believed that better still would be the plan of planting only one vine in a large house. This I urged him to do, and in 1855 he built a span-roofed house 89 feet long, 16 feet wide, and 9 feet 6 inches in height to the apex. In this house he planted a single Black Hamburg Vine in March 1856, the roots all outside, and the border prepared 89 feet in length by 15 broad. Beyond this border are the borders of other houses, giving it scope for its roots little if at all under a quarter of an acre. The vine is trained with a leading stem from the centre of the north side wall up to the apex, and down to the south wall, for the house runs east and west. From this main stem five laterals are trained towards each end of the house—one at the apex, the others equidistant between the apex and the walls. The last time I saw it in company with Mr. Kay was in 1862. I saw it again in 1864, when it had a full crop of excellent grapes, weighing, as I have since learned, 476lbs. In 1865 it bore 400lbs. of grapes; in 1866, three hundred bunches, some of them weighing 5 lbs. It took seven years to furnish the house with bearing-wood. The girth of the stem where it enters the house is at this date, May 1867, 14 inches. Mr. Osborne, an old pupil of Mr. Kay's, has ably carried out his preceptor's mode of managing this noble vine; and I trust it may long remain in robust health, a fitting monument to the memory of one who had few equals as an enthusiastic cultivator of the vine, and one who stands alone as having built a large house and planted it with a single vine to test a theory which some writers of the present day are starting as a new one.

Having thus placed the "extension" or one-vine system before my readers in the light in which I have long viewed it, I will, as briefly as the subject will admit of, take a review of what is said against the "restrictive" or many-vine system. The opponents of this latter system of vine culture take their key-note from Mr. Cannell, nurseryman, Woolwich, who when gardener at Portnall Park was so unsuccessful as a vine cultivator that he has chronicled the death of all the vines he then had charge of, after passing through nine stages of decadence, which Mr. Tillery, of Welbeck, has com-

pared to Shakespeare's seven ages of man, and described in very good verse in the *Nottingham Guardian* of March 15th, 1867. Mr Cannell's vines, we are bound to believe, did; but I am quite certain he is in error when he attributes their death to the "restrictive" or one-rod system. I know many very old vines that have been cultivated on the "restrictive system," and that have continued in perfect health for many years. At Oakhill, near London, Mr. Dowding planted a number of vineries forty years ago; I became acquainted with them in 1837, and for twenty subsequent years Mr. Davis, who succeeded Mr. Dowding, produced the most regular and finest crops of grapes in the kingdom from these same vines; yet they maintained their health, vigour, and fruitfulness. They were planted one vine to each rafter, and the system of pruning was the "close-cutting" one, by which only one eye was left at the base of each lateral.

There is an old vine referred to in this work, at Wrotham Park, which is eighty years old, and has all along been cultivated on the "restrictive system," for it only clothes two rafters; yet I learn from Mr. Edlington, who now has charge of it, that it is in as full health and vigour as any of the younger vines, and bears equally fine fruit, and has a stem 1 foot 7 inches in girth. True, the border it grows in has been once renewed in the time. In regard to this old vine, I make the following extract from a letter from Mr. Edlington, just to hand. He writes, "The old Hamburg produce fruit equal to the other and younger vines in the same house. Last year they were truly magnificent, surpassing all other grapes on the place."

I might go on multiplying instances to prove that vines neither become unfruitful nor die off in nine years, as Mr. Cannell's did, because they are not allowed to extend the area of their foliage annually, but I think such unnecessary. The fact is, that the vine is a very docile plant; and if its foliage is kept free from the attacks of insects, if over-cropping is avoided, and the wood well ripened—if the border is made of moderately good materials, and the drainage sufficient, the vine will continue in health and vigour for fifty years under any of those systems of pruning and training that are practised by gardeners of intelligence, whether that be the "restrictive" and close-pruning system, or the "extension" and long-spur system.

I therefore close this chapter as I began it, by saying, that there is much truth on both sides of this question.

Where it is necessary to have circumscribed borders, as is generally the case, I would plant a vine to every 6 feet run of a vinery, and grow two rods from each plant. This would give such vigour to the root as would rest on the branches in such a way as to yield both good bunches and berries, while, at the same time, a border 20 or 30 feet wide would afford them sustenance for many years.

Where there is ample scope for the roots to run unchecked and uninjured for 150 or 200 feet, then by all means adopt the one-vine or "extension" system, inarching or grafting on to this patriarch all the varieties required.

Calendar.

WORK FOR WEEK COMMENCING AUGUST 24.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—The winter stock sown last month will now be coming forward for planting out. Where onions have been cleared off is generally the best place for cabbages for spring use, because the ground, having been well manured for the onions, is in good heart, and yet so far relieved of manure by the onions, there will be no fear of a rank growth, such as will cause the plants to suffer from frost. Plant out as spaces become vacant, first digging deep, and leaving the surface rough. The planting, however, must be firm, and damp weather should be chosen for it. It is too late now to sow any more winter greens or onions; and if the stock is short, it will be better to get a supply of plants than waste time and patience in sowing. Thin winter spinach to six inches from plant to plant; thin the rows of lettuce that are to stand the winter, but not severely, because in the event of severe frosts the plants protect each other if somewhat close together. On the same principle, broccoli and cauliflowers left to risk it in the open ground should be not more than fifteen inches apart each, and the ground for them should not at this season be very rich, or they may suffer in severe weather. Earth-up celery in dry weather, but if not well grown give plenty of liquid manure, and postpone the earthing-up till the plants have made good substance. This is the best time to form new beds of horseradish, the crowns to be planted fifteen inches deep and six inches apart, in very rich and well-trenched soil. Continue to sow saladings, and gather seeds as fast as they ripen. Potatoes to be taken up as the tops wither; carrots and beetroot may remain till the frost cuts off the foliage, and no longer, but parsnips may be left in the ground, trenched out as wanted for use, unless the ground is required, in which case store them in sand.

CELERY to be earthed-up only when it has grown to its full size. It requires five weeks to blanch it, and it grows but little after the earthing.

CUCUMBERS are mostly beginning to fail now, or will shortly, so those who want a succession of fruit must be on the alert. Sow or strike cuttings, the latter to be preferred, and get ready to make up new beds. Old plants still in vigour must have the help of linings, and be covered with mats at night. Beware of mildew; if it once appears remove the affected leaves, and give the plants a sprinkling of sulphur.

TOMATOES will ripen well while this weather lasts, but in case of a change to chilly weather, it should be borne in mind that when the fruit is fully grown it may be ripened on a shelf in the greenhouse, if out with some portion of stem attached.

Flower Garden

FLOWER GARDEN.—Remove decayed flower-stems, and keep the borders clear of weeds, so as to prolong the season as much as possible. Plant out pinks and carnations, and rooted cuttings of herbaceous plants. The beds of seedlings must be looked over and thinned, and the thinnings planted in fresh pots of newly-dug and firmly-trodden ground. This month commences the season for planting bulbs. The first lot of hyacinths and tulips should at once be got into pots, and plunged in rotten tan or coarse sand, so as to quite bury them, and keep them only moderately moist, and as much as possible free from the action of the atmosphere, so as to induce a root action before the foliage is produced.

Hyacinths may also be planted in beds and borders, but tulips should not be put into the open ground till next month. A very effective way of using hyacinths is to plant them in patches of seven— one in the middle and six round it—every separate patch to be of a different colour. Cuttings of bedding plants may still be taken freely, but there should be no delay, or they may not be well rooted before cold weather sets in. This and next month are the best times for striking calceolarias. Take off the young shoots from near the bottom of the stool, and put them pretty close together in five-inch pots, well drained, and filed up to near the rim with a mixture of peat, loam, and sand, equal parts, and half an inch of pure sand on the surface. China roses may also be struck now in pots in the greenhouse, and they do best under hand-glasses. A second bloom, to last till Christmas, may be obtained from fuchsias by cutting in the young wood, and giving the plants a little heat to start them afresh. Geraniums struck early in the summer will now be coming into bloom to keep the greenhouse gay all the winter.

ANNUALS, to bloom early next season, should be sown at once on hard ground, in a dry position; if elevated above the general level, all the better. The following are the best leading sorts to sow now, to be transplanted in March, to bloom in clumps or masses, when the bloom will be much finer as well as earlier than from spring-sown seeds: Calliopsis, Clarkia, Collinsia, Convolvulus minor, Godetia, Escobolzia, Hibiaca, Iberis Kermesina, Jacobea, Larkspur, Lupinus, Nemophila, Nolana, Poppy (dwarf French), Schizanthus (dwarf), Silene rubella and armeria, Viscaria oculata, Venus's Looking-glass.

BULBS to be procured at once, and potted or planted as required. Bulbs to be planted in borders now occupied with flowers may be started in reserve beds, on moss or leaf-mould, or in clumps in rich sandy compost. When the borders are cleared they can be transplanted without injury to the roots, and the bloom will be finer than by delaying the planting till the end of October or November. Crocuses that have got mixed may be treated in the same way. Remove them at once to a reserve bed of rich sandy soil; there let them bloom, and then separate them, and plant while in flower in the places they are to occupy permanently.

CHRYSANTHEMUMS.—Cuttings of pompones put in now, and rooted quickly on a gentle dung-heat, will make nice little plants to bloom at Christmas in the house. They must not be stopped at all, and have rich soil to grow in. Short cuttings should be taken, so that there will be no necessity to use sticks to support them. Look over all large specimens, whether in pots or borders, and tie out securely to make them safe against storms.

INTERMEDIATE STOCKS to be potted in thumbs singly, and kept shaded till they make fresh roots. Sow Queens, Intermediates, and Bromptons; the soil to be a sound turfy loam, without dung; manure will make them too sappy to stand the winter well, but a poor soil will be likely to cause a large proportion of single flowers.

PANSIES to be propagated now in quantity for planting out in October, and to pot for early blooming in pits in spring. Those lately struck to be planted out in beds of turfy loam, with a liberal admixture of sand and charred rubbish, but very little animal manure.

ROSES layered now, and left undisturbed till April next, will then be found well rooted, and may be taken up and potted for bloom the following autumn. Roses lately huddled to have the ties loosened. Where buds have failed, others may be inserted either on the stems of young stocks or on suitable shoots lower down than those previously worked. Prune pillar roses, so as to remove a moderate amount of both old and young wood; that left to be its full length, and at such regular distances that there will be good symmetrical heads next season. Short cuttings of Chinas and Perpetuals will root now in the open ground under glasses.

AURICULAS may be increased now from offsets; if rooted, all the better; if not rooted, put them round the sides of pots, and they will soon strike. Auriculas not yet repotted must be attended to without delay, to ensure new roots before the temperature declines.

BORDER PLANTS of questionable hardiness to be taken up at the end of the month and potted, or at least one or two of a kind to propagate from, and prevent entire loss. Choice Pentstemons, Rudbeckias, &c., are sometimes cleared off during winter. The potting of one of each will at least ensure the saving of the variety.

CARNATIONS AND PICOTEES, from layers, to be potted off as soon as well rooted, and cuttings taken at once of all good seedling Dianthus in the borders. Where the propagation of carnations has been delayed, they may be increased by cuttings under bell-glasses, but when raised so late they must not be expected to bloom next season.

HOLLYHOCKS to be propagated at once. The shoots that rise at the base of the flower-stem are to be put in as cuttings round the sides of pots.

VIOLETS may be taken up from the borders, and potted in a mixture of rotten turf, rotten dung, charred rubbish, and road-sand, equal parts, for early bloom. In taking them up, do not break the root more than can be helped, and have good balls to each patch. Shallow pans of seven inches wide suit them better than pots. Put them in a frame, sprinkle and shade, and give very little air for a fortnight; then let them be exposed to all weathers till the end of October; after which give them frame culture.

IMPROVEMENTS AND SEASONAL WORK.—Now that the season is nearly over, it is well to make a review of plans, stock, and appliances, with a view to improvements and economy. While the foliage remains on the trees, errors in planting may be noted down for remedy, and the best places chosen for all shrubs and trees it is intended to plant this fall or next spring. The autumn hues, which increase and deepen as the flowers depart, give quite a peculiar interest and beauty to plantations and shrubberies; and in all arrangements in regard to planting the autumnal effects of contrasted tints of foliage should be considered, and for the next two months we have every opportunity of observing how much variety and how many charming effects may be obtained by a judicious assortment and grouping of trees and shrubs. In regard to bedding plants, the most accurate estimates may be formed as to the suitability of the kinds which have been used this season for soil and climate and local circumstances, as well also as to blendings and contrastings of colour, and the methods adopted in planting the beds. Where stock is wholly or partially raised at home, the gardener should now have a tolerably accurate idea of the varieties and quantities required for next season, that sufficient of each may be secured, and no more; for to be burdened with twice or thrice as many geraniums, verbenas, &c., as are likely to be wanted is as bad, or perhaps worse, than having too few. Whatever alterations are to be made in garden plans, too, should be definitely determined at once, so that the ground may be trenched up, and deciduous trees got into their quarters before the earth begins to cool, and walks, excavations, &c., made before

unfavourable weather begins to interfere with such operations. Delay is a more frequent cause of failure in every department of gardening than all others put together. Trees planted in spring never do so well the next season as those got in in autumn; rotation crops of all kinds do better on ground that has been ridged up betimes, and exposed to the autumn rains and winter frosts; for the deluging rains with which our winter usually commences are as fertilizing as manure, and no time should be lost in trenching over all unoccupied plots, and getting the ground everywhere into order.

Fruit Garden and Orchard House.

STRAWBERRIES to be forced should now be strong in pots; shift them to pots two sizes larger, using a rich firm soil well rammed in, and after potting keep them close in frames for a week; then set them out on coal-ashes, and keep well watered.

Greenhouse and Conservatory.

GREENHOUSE.—It is most important to have the growth of all hard-wooded plants well ripened while there is plenty of sun-heat. If any subjects requiring to be repotted have been neglected, there must be no time lost to give them a shift to enable them to make new roots before winter sets in. A border under a south wall is a good place for plants that require to be well roasted before being housed. Bedding plants should be got into small pots as fast as they make good roots in the borders, or can be spared from the decorative grounds, if worth keeping. Petunias, verbenas, and tropeolums come so readily from spring cuttings, and make as good plants as from autumn cuttings, that it is waste of glass to keep any large stock of cuttings through the winter. Keep the houses gay with balsams, cockscombs, fuchsias, lilliums, gladioli, coleus, amarantins bicolor, heliotropes, and plants with fine foliage. Wherever worm-casts are seen in pots, turn out the hells, and the worms can then be picked out with a stick. Sometimes a dose of manure-water will cause the worms to struggle up to the surface. Plants in conservatory borders which are now past their best to be taken up, and if worth keeping pot them, and place on bottom-heat for eight or ten days, as they will winter better if the pots are full of roots. Winter-flowering begonias to have a good shift in a compost of turfy loam and leaf-mould. Pot off a lot of bulbs at once for early bloom, and plunge them in coal-ashes, and give very little water. Keep all houses open as much as will be safe; house tender subjects that are likely to suffer from wind and rain. Pot a few bulbs for early bloom. Ornithogalum, Ixia, and Sparaxis force well, and Narcissus bulbocodium will be useful if kept in ordinary greenhouse temperature for early bloom.

AZALEAS AND CAMELLIAS to be syringed frequently, but not so much watered at the root as during previous months.

CINERARIAS ought now to be strong from rooted offsets, and some will want a shift. Use good compost, moderately sandy, and plenty of drainage.

CALCEOLARIAS should now be propagated in quantities. A bed in a frame is preferable to pans and pots, as they can be lifted out for planting with good balls, and are not so likely to die off as those wintered in pots.

PELARGONIUMS.—If the weather is cold or wet, house the plants a little earlier than usual, but with air left on night and day for the first week.

MILDEW will show itself in all close damp places now, and do incalculable mischief if not checked. Sulphur dustings are the best remedy, but fresh air and cleanliness will do much to prevent it.

Stove and Orchard House.

STOVE.—Plants in free growth must be moderately well ventilated, so as to induce a stocky habit, and prevent the formation of soft sappy wood, which will probably not ripen well. Remove shadings as much as will be safe, and place subjects that are going to rest in the coolest part of the house. See that all the winter-flowering plants are sufficiently potted, and any that are potbound, and must not be checked by a shift, mulch with sheep's dung, or assist by means of liquid manure. Plants with ornamental foliage will be useful now that flowers are scarce. In giving water, take care to avoid a chill, and in every case see that the drainage is perfect, as there is time now to repair any small mischief before winter. As the month advances, let the heat of the house decline, and generally use as little fire-heat as possible, especially where the stock consists chiefly of plants that will be at rest all winter. Great care, however, must be taken that soft-leaved plants do not get affected with mildew. A few tropeolums struck now will be useful in the stove for winter blooms, and many ordinary garden subjects may be turned to account for decoration by getting young plants forward, and giving them a liberal shift before taking them into the house. Amaryllises should be looked over, and a few potted and put into a tan-bed.

Forcing Pit.

MELONS must have aid from bottom heat, or the fruit will drop, and that now ripening will have no flavour. Keep the vines regular and thin, and shut up early. If any difficulty in getting the fruit to ripen, the following plan may be adopted: Cut the fruit with as much stalk attached as possible; place them on shallow cups or any convenient vessels, with about a glass of wine in the vessel, and the stalk of the fruit dipping into it. The hottest part of a lean-to house will be the proper place to ripen them off; the wine will be absorbed, and the flavour of the flesh improved; and a few days' sunshine will ripen them perfectly.

PEACHES to have as much air as possible, therefore remove any subjects that require to be kept closer, in order to admit a thorough draught among the trees, and if the lights can be taken off all the better. If the wood is not well ripened now, it never will be, and advantage must be taken of fine weather to make sure of it.

VINES forced early will now be disposed to break. Let them have a temperature of 55° to 60°, not higher, till the leaves are developed. Shade the fruit that is to hang any length of time, and keep a sharp look-out for vermin.

ABSENCE OF MIND.—A gentleman, after noting the state of the weather previous to going to bed, hung his thermometer, as he supposed, outside of his dormitory window. About four o'clock in the morning he was awakened by a policeman, who informed him that a gold watch was hanging outside of the window, and advising him to take it in. He had placed the thermometer under his pillow, and hung his watch out of doors. It is related of a Scotch Professor that he was one day crossing the road, and accidentally stumbled against a cow. In his confusion he lifted his hat and said, "I beg your pardon, madam. A few days after he unfortunately bounced up against a lady, and remembering his former adventure, said "Is that you again, you brute?"

Literature.

La Canna, son Histoire, sa Culture, par E. CHATE FILS. Paris: 9, Rue Cassette.—This little brochure on the history and cultivation of the Canna will be found interesting and valuable, and in every sense a handy book on the subject. Every branch of cultivation is treated of, and there is a copious list of species and varieties. The historical notes on the introduction of species and the sources of varieties (pp. 32 to 35) during the period 1848 to 1866, are particularly worthy the attention of hybridizers and cultivators generally.

Dicks's Shakspeare. Complete Edition. Dicks, 313, Strand.—This is the "Shilling Shakspeare," a small octavo volume, an inch and a half thick, weighing 2½ oz., and comprising over 1,000 pages of letterpress, of far better quality than we should have supposed possible for the money. It is a curiosity for such as already possess good editions of Shakspeare, but to the poor but ambitious artizan, to the youth hungering and thirsting to make acquaintance with the works of the great poet, this edition is a boon of far greater value than it may at first sight appear, for in truth it has a national value and importance. Nor is it to be despised as a cheap portmanteau edition for folks who cannot comfortably travel without Shakspeare for a companion; and a few shillings might be worse spent than in binding a copy of this edition for rough uses and carrying about. It happened strangely that, on first opening the volume, we lighted purely by accident on the following passage in *Romeo and Juliet* (act ii. sc. 2), which we transcribe, in the hope it may delight many readers as it has delighted us, with a delight mixed with surprise, and confirming the opinion now generally prevailing, that Shakspeare is a perpetual astonishment, for his best-known passages never lose their freshness, and with use and wont augment rather than diminish in beauty and power. For such of our readers who do not enter into this view of the subject, we present the following as a sample of the author's style, and as proving that William Shakspeare was really a clever man:—

Enter Friar Laurence, with a basket.

Fri. The grey-eyed morn smiles on the frowning night,
Checking the eastern clouds with streaks of light;
And flecked darkness, like a drunkard reels
From forth day's pathway, made by Titan's wheels:
Now, ere the sun advance his burning eye,
The day to cheer and night's dank dew to dry,
I must up-fill this osier cage of ours,
With baleful weeds, and precious-juiced flowers,
The earth that nature's mother, is her tomb;
What is her burying grave, that is her womb;
And from her womb children of divers kind
We sucking on her natural bosom find;
Many for many virtues excellent,
None but for some, and yet all different.
O, mickle is the powerful grace that lies
In herbs, plants, stones, and their true qualities:
For nought so vile, that on the earth doth live,
But to the earth some special good doth give;
Nor aught so good but, strained from that fair use,
Revolts from true birth, stumbling on abuse;
Virtue itself turns vice, being misapplied;
And vice sometime's by action dignified.
Within the infant rind of this small flower
Poison hath residence, and medicine power;
For this, being smelt, with that part cheers each part;
Being tasted, slays all senses with the heart.
Two such opposed foes encamp them still
In man as well as herbs, grace, and rude will;
And, where the worse is predominant,
Full soon the canker death-feats up that plant.

UNFERTILE BLOSSOMS ON DWARF PEAR TREES.

By DR. J. S. HOUGHTON.

About one year ago I called attention to the unfertile character of the blossoms on certain pear-trees, which annually exhibit a great profusion of flowers, and yet produce but little, if any, fruit. I inquired what was the cause of the barrenness of the blossoms, and suggested that the botanical structure of the flowers ought to be examined by competent persons, in order to ascertain wherein they are defective. The particular variety of the pear to which attention was called as unfruitful, even after being covered with blossoms, was the Duchesse d'Angoulême on the Quince stock.

I am happy to say that the proposed investigation into the botanical condition of the blossoms was made about the 1st of May last, by several skilful botanists on my grounds, and part of the report will now be presented to the public.

At the time of the examination there were several thousand Duchesse trees, eight, ten, and twelve years old, in full bloom, in close proximity to other varieties which are not so unfertile. The Duchesse trees were what gardeners call "one sheet of bloom." The opinion of all present seemed to be, that so much "bloom" must be very exhaustive.

Mr. Thomas P. James, botanist of the Pennsylvania Horticultural Society, examined the flowers very carefully with strong lenses, and said they were (as compared with flowers of other varieties) very weak in their organization, although apparently perfectly hermaphrodite; that the stigmas were evidently feeble, the pollen limited in quantity, and the entire flowers in a low state of vitality.

The season was very unfavourable—cold and wet—but the flowers examined had not, at that time, been seriously injured.

A large quantity of the Duchesse blossoms were examined very minutely by Professor Horatio C. Wood, Lecturer on Botany in the University of Pennsylvania, under the microscope, and I have much pleasure in appending his very acute observations upon this deeply interesting subject. I trust that pomologists will not let the matter stop here, but that they will discuss the best method of avoiding an excess of weak flowers on fruit-trees—or, rather, the best means of producing a proper quantity of strong, well-organized, and well-developed fruitful blossoms.

PROFESSOR WOOD'S REPORT.

I have examined the blossoms of the Duchesse d'Angoulême pear. They are certainly sexually perfect, with both the male and female organs apparently normal to the naked eye; but with the microscope I find both the gynoecium and androecium (to use a medical phrase) suffering from general debility. Thus, the anther-cells externally appear to be well developed, large, and finely formed, but they contain scarcely one-third as much pollen as similar organs of more fruitful varieties. It seems to me, further, that the pollen grains themselves are not so well developed, nor so crowded

with granules or fovilla. In the same way the female organs are defectively organised. For instance, the stigmas are not so large, and the little papilla, which secrete the so-called stigmatic fluid, are not nearly so numerous nor pronounced as in the flowers of neighbouring trees.

In my own mind there is not much doubt but that these evident marks of the want of vigorous sexual development have a deeper meaning than appears at first glance. What if there are comparatively few pollen grains? Providence has so provided that the great mass of the pollen is superfluous, and ordinarily is wasted. Surely the mere absence of a part of this superfluity would not produce the barrenness you complain of. It seems to me highly probable that the appreciable want of strength is associated with a similar, but less apparent, degradation as regards quality; and there is a consequent want of power in the germinal matter both of the pollen and ovary, which is the real cause of the sterility. If this explanation be not the correct one, I know of no other.

Having thus made a diagnosis in the case, the next step is, if possible, to discover the cause of the condition, so as to remedy it if practicable. Is it not probable that the source of the trouble is to be found in the excessive production of blossoms, which this variety of pear is notoriously addicted to? Of all the various life functions of the plant, the process of seed-producing is, *par excellence*, the exhaustive one. It is well known how it often cripples, or even kills, a previously vigorous tree. Further, the period during the reproductive process, the worst for the plant, in which it eats up its life-capital fastest, is that in which the blossoms are perfected, the pollen shed, and the ovule impregnated.

The reasons for this are obviously twofold. In the first place, the production of very highly-vitalized matter rapidly exhausts both the plant and the animal. Now it is at the period alluded to that we have the greatest elaboration of costly products in the flower. Not only are the ovaries, with their contained ovules, and the anthers with their myriad pollen grains, rapidly developing, but the sepals and petals, with their numerous oil glands, are aiding in the prodigal waste of the strength the plant, mayhap, has been years in obtaining. It is readily seen that after impregnation, during the slow gradual production of the fruit and seed, we have no such sudden burst of life activity.

Again, at this period there is, probably, the greatest loss of nitrogenized principles that occurs during the life of the plant. When the leaves are about to die their nitrogenized contents return to the stem and roots, showing the great value to the plant of these principles. The seeds, to be sure, contain much nitrogenized material; but then there are comparatively few of them perfected. Not so with the pollen. You can often see it almost making little clouds in the air, or dusting thickly the surface of ditches with its countless granules, and each of these is literally gorged with the most highly vitalized nitrogenous material the plant can produce. Surely, then, there is evident cause for the exhaustion of flowering, especially when we take into consideration the rapidity of the process as compared with the length of time through which the seed is perfecting. That the blossoming is very exhaustive, that in it are expended most rapidly the life forces of the plant, we have numerous proofs. Thus the effects of profuse flowering on very young trees is well known.

Further, in the flower we have a rapid oxydization of carbon, or, in other words, a destruction of the bone and sinew of the plant; which is proven not merely by the evolution of carbonic-acid gas, and the taking-in of oxygen by the blossoms, but by the heat given off from the flowers—an indisputable proof that there is a more or less rapid burning up of carbon in the flowers themselves, strengthened as it is by the interesting results of the experiments of Garreau, Vrolik, and De Vriese. Thus, the latter savans found that the increase of temperature was much more marked when the plant-blossom was placed in oxygen than when it was in the air, and that all evolution of heat ceased when it was placed in nitrogen or carbonic acid—or, in other words, when it was deprived of oxygen; while M. Garreau showed that the well-known periodical increase and decrease of temperature in the blossom was accompanied by a similar increase and decrease in the amount of carbonic acid evolved.

The rapid absorption of cold water by the root from the soil, the constant evaporation from the foliage, the facility of radiation and conduction from the wide-spread open blossoms, with various co-acting circumstances, cause so rapid a loss of heat from ordinary flowers that the increase of temperature is only sensible to very delicate instruments, such as the thermo-electric pile; but when there is a mass of flowers on a dense spike or spadix, shut up as it were in a spathe, the heat developed is more marked. Thus in some tropical Arums, a difference of 10° or 12° has been noted between the outer air and the immediate vicinity of the flowers.

To sum up, in conclusion, it seems most probable that weakness of the sexual organs is the cause of the sterility of the Duchesse, and that this weakness is dependent upon excessive blossoming. If this be so, the indication is evidently to check this excessive flowering.—*American Gardener's Monthly*.

[Readers of the Magazine have been frequently advised to thin the blossom buds of free-flowering pears. Many other fruits besides pears would be benefited by the process.—ED. G. M.]

Correspondence.

HOUSE FOR WINTER CUCUMBERS.—I have been a gentleman's gardener, and am now a market gardener in a small town of about 5000 inhabitants; and, with the view of increasing my income, think of erecting a cucumber house, as economically as is consistent with utility, heated by hot water, to grow cucumbers in winter, having no doubt that I should find sale for them at Covent Garden. I have had great experience in growing cucumbers in frames, but not by hot water; but I apprehend I should have no difficulty. I think a house about 30 feet long with span roof, and about 16 feet wide, would grow a nice quantity, if properly constructed and managed. I have no wall for a lean-to. Will you kindly give me an idea of the size and quantity of pipe I should require, and size and description of boiler; and the best way of having the pits in the cucumber house; and advise generally as to the sort of house most likely to pay? ARTHUR.

[A span-roofed house is undoubtedly the best for the growing of winter cucumbers, as it furnishes more light than a lean-to; but a house 16 feet wide, as suggested by our correspondent, is by no means the most useful or the most economical. As economy consistent with utility is the object, we should reduce the width to 12 feet clear. To obtain an angle

of 45 degrees (50 would be better) to a span-roofed house 16 feet wide would require a much higher roof than is desirable for cucumbers, besides being more expensive. Moreover, a width of 16 feet is more than is required for the pathway and pits to hold the soil. In a width of 12 feet we have first a walk through the centre of the house 3 feet wide, with a 4-inch wall on each side; then on each side a pit 3 feet in width, with another 4-inch wall. We have then left a space of twelve inches between the foundation wall and the wall which forms the pit. But the annexed sketch will give a better idea than a description, as the position of the pipes and that of the soil and rubble are shown. We prefer to have the pit in which the plants are grown separated from the foundation walls, as it gives a better position for the pipes for top heat. Three pipes on each side are shown for top heat, and a flow and return in each pit surrounded with rubble for bottom heat. Means should be provided to admit front air either by a small sash or a boarded ventilator on each side, with the same provision at the apex. The pits will require to be 3 feet 6 inches deep. And as our correspondent says nothing about a tank for bottom heat, we conclude he intends to use rubble. Of this he will require a depth of 2 feet, chiefly over the pipes; this will leave 18 inches for the soil. The length of the house must be decided by the quantity required to be grown. A length of 30 feet will not furnish any great number every week from the first of November to the first of March. It would possibly suffice for a town of only 5000 inhabitants, but for Covent Garden supply it is another matter; on this point, however, perhaps the less we say the better. But after the first cost an additional length of 20 feet would not be a serious matter, as a house 50 feet long would be heated with only a little more labour, and not

SECTION OF CUCUMBER HOUSE.

much more expense as to firing, than one of 30. For such a house we should advise that 4-inch pipes be used both for top and bottom heat, and that evaporating pans be used largely to create moisture in the air. For a house 30 feet long a 27-inch saddle boiler will do admirably, and the saddle boilers are to all intents and purposes second to none. But it is as well to remember that the size of the boiler must be in proportion to the quantity of piping. At page 478 of last year's volume, our correspondent will find that Mr. Clarke went fully into the subject of cucumber houses, sections of which are there given. He may possibly find further information if he reads the article in question; and as to their cultivation, the article of a Kentish Gardener, in the number for August 3rd of the present year, is so thoroughly practical that it cannot fail to be useful to those who are not much experienced in growing cucumbers in houses.]

INQUIRIES ABOUT SOME BEDDING PLANTS.—*White Lobelia*: Can any of your readers who have grown the little *Lobelia Miss Murphy* favour me with the result of their experience of it in the beds or borders, as I did not secure my plants sufficiently early for me to judge properly of its merits? I have some doubts about it as an effective bedding plant, and should like to have them verified or dispersed.—*Irene Herbistii*: I noticed the failure of this with our Editor, and I have to record a similar fate of the first planting here. And the second ended quite as abruptly; for after allowing a long line to remain without making any progress for six weeks, I became so disgusted with it that I cut it up, and vowed I would never plant it again. Some two or three dozen plants standing in another part of the grounds were killed down by frost; and those of the second planting, although allowed to remain, have made but little progress, and the colour is a dirty sombre black. I should be glad to know if this is the case generally this season.—*Cloth-of-Gold Geranium*: With this variety of *Geranium* I am sadly disappointed this year. It has made but little growth, and the edges of many of the leaves have the appearance of being scalded, for they wither into tinder. Is this so in other parts of the country? Hitherto it has been first favourite with me; but when I look upon a long line of the *Golden Chain* we have here, I am obliged to admit its superiority over *Cloth-of-Gold*, and therefore rather reluctantly indorse the opinion of the Editor in all he has said in favour of old plants of *Golden Chain* (as I still have some affection for the other). Many of the plants here of *Golden Chain* are six and seven years old.

J. C. CLARKE.

BALSAM OR BALM.—Here is a charming story ready to the hand of HANS CHRISTIAN ANDERSEN: "The garden of the Middlesex Hospital was thrown open for the flower show of the window-grown plants in the parish of St. Andrew's, Wells Street, on Tuesday. On this occasion the flower show for Christ Church, Down Street, was combined with it. The display of plants was very good, considering the badness of the season, and the show was crowded all the afternoon with the poor of the neighbourhood. The prizes were distributed by Lady Mildred Beresford-Hope, and the Hon. Mrs. William Cowper—two out of a long list of patronesses. Among the prize-holders was one of the hospital nurses; and a prize was also adjudged to a balsam grown by a poor crippled boy by his bed-side in the *Pepys Ward*." Even old *Pepys* himself might have been touched by this simple recital! Such peeps into the diaries of the life of the poor should do good. Let us hope our quotation of the paragraph will benefit so excellent a movement as that of "Window-grown Plant Shows."—*Fun*.

The Gardener's Magazine.

SATURDAY, AUGUST 31, 1867.

THE SEVERE FROSTS of the 23rd, 24th, and 25th of May last were so marked in their effects on vegetation, that almost every kind of produce of the present season, in field and garden alike, is reduced in quantity and deteriorated in quality below the average, and we are compelled to call those ungenial nights to remembrance while striving to enjoy the warmth with which the harvest has been favoured. Ask the farmers in the eastern parts of England about potatoes or wheat, and they will say that the May frosts did them both so much harm, the first especially, that the total bulk of the crop is considerably reduced below what the early growth of the plant promised. Many great breadths of newly-sown seeds were killed outright, the young growth of forest trees was blackened, and the orchard fruits were nipped in the bud, and the trees are now but lightly laden. But it is in the garden that the injury resulting from frost at so advanced a period of the year is most plainly seen. Nearly every kind of hardy fruit has been scarce, those grown on walls especially so; and of the fruits yet to be gathered there is generally speaking but a small promise, and many of the best winter fruits will be scarce and dear. There are exceptions of course. We write this within view of as pretty a display of outdoor fruits as may be seen anywhere in England; but we have seen barren plum-trees, barren pear-trees, barren walls, and signs of general failure in districts far apart, and the cultivators all agree that the May frosts did the mischief. In view of the facts of the case, we may find in hornbeam and arbor-vitæ hedges, in shelter of various kinds, and even in perfect drainage of the soil, some means of counteracting the evils incident to late spring frosts; but the most important lesson to be learned from the experiences of 1867 is that GLASS is our only trustworthy shield against the elements, our only antidote to the rigours of this most uncertain of climes. There is no certainty, and there never will be a certainty unless the climate should alter, that when we plant a tree we shall ever see its fruit; there is not a single day in the whole year but on which frost is possible, and has actually happened, in this country. On many days in the year frost is of little consequence, but perhaps its occurrence at the time when fruit-trees are in bloom is most to be feared by the cultivator who desires fruit. The severe frost which occurred in July, 1863, and which killed down the brake on exposed commons and in damp valleys, was but slightly hurtful to the fruit crops, though in many places it completely destroyed the flowers of the garden. The spring frosts are those against which we especially need to protect our trees, and, generally speaking, the loss of one year's crop in any well furnished garden would be the equivalent in value of the cost of the glass that might have saved it.

Cheap glass structures are now obtainable everywhere. In the vicinity of towns and cities there are horticultural builders who understand the requirements of the fruit cultivator, and are ready to construct suitable houses at reasonable rates of charge. The admirably-planned orchard houses of Messrs. Hereman and Ormson have done much towards the multiplication of our home-grown fruits, and, what is not less important, the assurance of a crop from year to year irrespective of the spiteful changes of the weather, that form such painful themes of common conversation. Elaborate and costly structures are not needed for fruit culture; the requisites are plenty of light, plenty of air, and room enough to prevent overcrowding and overshadowing, and to afford the cultivator proper convenience for reaching with ease every part of every tree. The larger the house the better, for large houses are least affected by sudden changes of temperature, and they admit of being freely ventilated without any rush of air, such as might prove injurious. But small houses are not to be despised. Let every lover of fruit obtain the aid of glass if he can, and cut his glass according to his purse, according to the teaching of the proverb on the relations of the coat to the cloth it is to be made of.

Glass would have been much more generally employed for the growth of fruits if the pot system of cultivation had been less ardently advocated. Potted fruit-trees are extremely pretty toys,—fruitful toys, but toys after all. Let those who want toys have them; why should any one complain? But it must always be understood that if time is of value, and if every operation in the garden is to be considered as costing in money so much, the fruit produced by

potted trees will never pay for the labour demanded for its production. The only profitable mode of growing fruit under glass is to plant out the trees, and give them room. Extension! Ha! we must follow the extension system to have peaches, nectarines, plums, and pears, under glass; that is to say, extension as compared with pot culture, giving the trees reasonable head room and root room, and putting fruit upon our walls and trellises in hundreds, instead of upon the twigs of miniature trees in pots by dozens. As to heating, it must be evident that the power to keep out frost is always an advantage; where forcing is practised, heating is of course absolutely necessary. Nevertheless in almost every part of Britain glass alone, without any heating apparatus, will suffice to ensure a fair and constant production of the most esteemed of garden fruits; and, as a rule, fruit-growing under glass will always make a good return for every reasonable outlay.

THE interesting and valuable summary of horticultural affairs in connexion with the Paris Exhibition with which English readers have been favoured by the *Times* correspondent will, we have no doubt, by the happy style of expression, and the broad views and sound principles of the writer, remind many of our readers of the continued existence and flourishing condition of a certain "W. R." It is a gratifying circumstance that horticultural interests have at least one faithful and competent representative on the part of British practitioners; whether there be another entitled, even for a moment, to any sort of attention we have yet to learn.

THE HARVEST OF 1867.—The *Agricultural Gazette*, as usual, has procured from all the counties in the island details about the harvest prospects and its progress. We extract our contemporary's summing up as follows: "The following table gives the number of returns under the headings 'Over Average,' 'Average,' and 'Under Average,' respectively; and a comparison may, at the same time, be made in it with the corresponding reports of the two previous harvests, both of which were considerably below the average productiveness:—

Crop.	Over average.	Average.	Under average.	Total.
Wheat { 1865 29	90	76	195	}
{ 1866 21	96	63	190	
{ 1867 21	76	112	209	
Barley { 1865 28	112	40	180	}
{ 1866 45	102	22	169	
{ 1867 32	116	53	201	
Oats { 1865 2	27	154	185	}
{ 1866 29	84	60	173	
{ 1867 46	105	48	199	
Beans { 1865 4	53	64	126	}
{ 1866 19	65	29	113	
{ 1867 36	94	30	160	
Peas { 1865 6	58	64	128	}
{ 1866 47	59	3	109	
{ 1867 18	85	51	154	

"It will be seen from this table that wheat promises a less satisfactory yield than even in 1865 and 1866; but it will be necessary that the reader should correct the impression gathered from the totals by an examination of the detailed reports, especially in our great corn-growing districts in the eastern and southern counties. Barley is probably an average crop as regards quantity of yield, but much of it must be of very inferior quality. Oats are a better crop than they have been for the last two years. Beans are generally remarkably good; but peas are considerably inferior to last year's crop, which was unusually good. For the rest, there is generally a fair promise of green crops, mangolds, and turnips. Potatoes exhibit more than usually abundant signs of the disease; and there has been a very heavy crop of hay, most of it well got in."

Our own opinion, says the *Worcester Herald*, derived from a tolerably broad survey, of harvest results in Worcestershire is, that wheat is fully one-fifth deficient of a good average; but it would seem that one person at least takes a much more cheerful view of matters, and we need hardly say how highly pleased we should be to find that his view turned out correct. "J. L., Worcester, Aug. 20," writes to the *Times* as follows:

"Winter wheat is averaging 12 bags to the acre, and the cost of labour varies from 10s. to 15s. per acre, in addition to from four to six quarts of cider; the crop may be considered a fair average yield, and in some places far exceeds the expectations of the farmers.

"Spring wheat is now quite fit for cutting, but in places is unusually laid, thereby causing the price of labour to vary considerably, from 12s. to so high a sum as 18s. the acre. The last few days of warm weather have in great measure advanced it to maturity. Oats are exceedingly good, though rather short in the straw, and bagged oats will, if all goes well, be off the ground in a few days. Farmers are paying from 8s. to 10s. per acre for good work, not including drink, four to six quarts being allowed.

"Of barley, though much laid in parts of Worcestershire, a fair standing crop may be seen in many places; but the late heavy wind and rain have much deteriorated the value of the grain. The price for labour varies of course on account of the difficulty in mowing laid barley; but the usual price given is from 3s. to 5s. per acre. Owing to the very good promise of seeds, farmers are forced to leave their harley on the ground longer than would otherwise be necessary. Beans are above the average

crop, both as regards corn and straw, the yield being from 11 to 16 bags per acre."

According to the reports of the Inspector-General of Agriculture, the wheat harvest is almost finished in two-thirds of the French departments, and, if the fine weather continues, in about ten days the whole will have been got in. The quality is said to be generally good, but the quantity will hardly suffice for a year's consumption. The reports on the vintage, furnished from the same official sources, are unfavourable. In both quantity and quality 1867 is expected to be inferior to 1866. The wheat crop of the present year in the United States is said to be, on Government authority, the largest that country has ever harvested. With scarcely an exception the various States show a large percentage of increase over last year's crop. It is said that over 225,000,000 bushels of wheat are being this year gathered, whilst last year's yield was but 180,000,000 bushels; and while the average crop in America for a long series of years has been 5 to 5½ bushels to each inhabitant, the crop of 1867 will give six bushels for each inhabitant.

GASES FOUND IN PLANTS.—Messrs. Faivre and Dupré have recently examined the gases found in the mulberry and vine, the parts which contain them, and the changes produced in them by the process of growth and development. In a communication read before the Botanical Society of Edinburgh, it is stated that they have arrived at the following conclusions:—1. The presence of gases in the interior of the root of the stem, and of the branches in the mulberry and vine, is a normal and constant fact. 2. The composition of these gases changes with the epochs of vegetation. 3. During the period of inactivity, carbonic acid is in very small proportion, and is scarcely appreciable. Oxygen is present to the same extent as in atmospheric air. During the phase of activity the contrary takes place, and the changes are more marked in proportion as the vegetation is more energetic; with the progress of vegetation, the proportion of oxygen diminishes. 4. In the roots, during the epoch of vegetation, the quantity of oxygen is not so great, while that of carbonic acid is greater than in the branches examined under the same circumstances. 5. In the branches, as in the roots, there is an inverse relation between the oxygen and the carbonic acid; by adding to the normal oxygen that disengaged under the form of carbonic acid, we obtain a number which is scarcely above the proportion of oxygen in the air. 6. In the mulberry and the vine, injections do not penetrate the pith or the bark, whether in the branches or roots. The ligneous layers are alone permeable to mercury. The more the formation of vessels increases, the easier and more complete are the injections. The injections are fuller in the roots than the branches; they are also more in the branches than in young herbaceous shoots. In the old stems of the mulberry, the central layers cease to be permeable. 7. Microscopic examination proves that the injection specially penetrates the pitted and reticulated vessels, and also the spiral vessels in the young herbaceous shoots. 8. The pitted vessels show distinctly the mercury in the areolæ, as if in so many little pouches formed by thin portions of the wall; the same observations have been made in regard to the reticulated vessels. 9. The contents of the vessels expelled by the mercury is variable. Sometimes gas only is sent out; this is the case in winter and after dry weather. Sometimes the gas is mixed with sap, which is more or less abundant according to the epoch of vegetation and external temperature. These two latter conditions regulate in a certain degree the contents of the vessels. 10. The contents are so variable that in plants the root vessels of which contain gases and sap the stem vessels contain only gases, or inversely. 11. The presence in the vessels of animals of oxygen and carbonic acid mixed with the blood constitutes one of the best established facts in animal physiology; the presence of the same gases mixed with the sap in the vessels of plants, and the modifications which they there undergo, seem to establish an interesting correspondence between these two kingdoms.

TAUNTON DEANE HORTICULTURAL EXHIBITION.

There is probably not another town, whether of less or greater dimensions, in the whole of Great Britain, that can compare with Taunton for enthusiasm and unanimity of feeling in respect of its annual horticultural exhibition. Every individual soul within the town, and for many miles around it, appears to partake of the inspiration of a great event, and a vast rosy smile of holidays spreads over the whole place, and ripples away on all sides into the country, so that far-off towns and villages are, according to their several degrees of distance, kindled with the true Tauntonian spirit of rejoicing. Your most humble servant, the reporter on this occasion, has seen many a population "turn out," and for a time trample business under foot in the pursuit of some common pleasure, but only here, in the thriving and usually quiet capital of Somerset, does this abandonment acquire dimensions and an intensity that entitle it to be called historic. Yet by its distinctness and self-assertion, by its associations and its import, by its comparative newness, and (let us hope) its certainty of a long and happy life, the horticultural exhibition, with all its surroundings in this most excellent nest of humanity called Taunton, is historic, and the youths of this day will rejoice when aged to tell how Taunton laid the foundations of its exhibition in 1866, and added thereupon a grand superstructure in 1867. We shall come to the show presently, but now we are on the way to it. Reporter of this is somewhat taken off his feet by the universality and largeness of the spirit of festivity in the wholesome thriving town. As to the experience of your obedient servant the reporter, peculiar sensations commenced at the railway station. I thought, on alighting, that some giant, a native of some larger planet than ours—Jupiter (that is to say, the planet Jupiter), perhaps—had selected Taunton Station for the purpose of securing a good stock of winter herbs for the kitchen; for on the iron tie-bars were suspended great bunches that at first appeared to be mammoth varieties of thyme and marjoram, but on closer inspection were found to be true terrene broom, furzo, laurel, and other such stuff. On looking round, every corner of the station was seen to be planted with trees, literally planted with trees—oak-trees, fir-trees, all sorts of trees, stuck in all sorts of places, and every tree in every place breathing in its looks a kindly welcome. On the way to the show, the first important demonstration was one consisting of May-poles and garlands, or something of that sort, in the front of a nursery on the north side of the Bridge. This was finished in the best possible taste, the scaffold-poles being completely clothed with rich leafage and flowers, and the festoons between them the same. Advancing into the town, flags and streamers, masses of evergreens, great inscriptions boldly wrought on coloured cloth, devices, decorations of all kinds, were seen on every hand, and continued in every conceivable change of character the whole of the

half-mile length of public way from the Bridge to the Vivary Park, where the show was held. The market-place was particularly gay with bright banners; at many points of the public ways festoons of flags were carried across and across in prodigious profusion; and as to the number of great fir, oak, and spruce trees displayed at doorways and windows, it seemed as if Birnam Wood had called at Taunton on its way to Dunsinane to show how it could be an omen and signal of pleasure, though so commonly regarded as otherwise. I was particularly struck with the beautiful arcade which adorned the extensive frontage of Mr. Jacobs, just beyond the market-house—a real tabernacle with roof of green boughs and an outside wall of trees, a remarkable and interesting affair, which must have cost money and labour, and was worth something, though for only one day's feast. Already, as I went up to be in time to perform certain official duties, the tradesmen were preparing to close their shops, and dedicate the day to the truly rural of the park and flower-show. There was a military band in operation on the parade, and the boys were crowding round the great devices, apparently made of a stout sort of macaroni, which were piled up in the market, and were said to be the fireworks that were to wind up the day with scintillation and coruscation, and cause inflammation in the eyes and admiration in the hearts of all beholders.

The Vivary Park is a capital place for a flower-show, being within a stone's-throw of every man's door for all the inhabitants of Taunton, yet a park in the proper sense of the word, and well adapted, if obtainable for the purpose, to serve as a public recreation ground for the district. There were five large marquees, all well filled with plants, fruits, and flowers, comprising over 500 feet run of canvas, covering some 1,500 (or more) square feet of floral luxury. There was but one set-off against complete success, and that was the unbearable heat within the tents at the time when they were most crowded. It does not appear to be the fashion to ventilate the tents as the London tent makers do so effectually and agreeably. It was fortunately only for a short time during the greatest pressure of an admiring public that this heat was felt, and throughout the whole of the time the gates of the park were open a large proportion of the visitors enjoyed the pleasant promenade on the cool grass, listening to the splendid performances of the band of the Marines, from Plymouth; the leader of which would do well to wear his proper uniform, instead of giving occasion for remarks, as he does, of a by no means flattering nature in reference to his unofficial costume.

The exhibition was good throughout, in some of its features remarkably so. In the marquee devoted to open classes, Mr. B. S. Williams, Messrs. Lucombe, Pince, and Co., Mr. Robert Veitch, Messrs. Dyer, Mr. Nelson, Mr. Drummond, and other great exhibitors, were present in full force, and there was as grand an exhibition of specimen plants as the average of a first-class London show. Mr. Williams certainly presented the finest group of the plants in the show, taking first place in the class for the best twenty stove and greenhouse plants. Mr. John Nelson, of Bristol, stood second, Mr. R. T. Veitch, extra. Mr. Drummond took the lead in the class for six, Mr. J. B. Saunders, the honorary secretary of the society, second. The prizes for fine foliage were divided between Mr. J. Nelson and Mr. Drummond. The class for eighteen exotic ferns brought a splendid hank of plants; Mr. Dyer was a good first, with exhibition kinds, all of large size, and quite fresh and bright; Mr. R. Veitch second, with small plants, in the midst of which was a beautiful specimen of the true *Adiantum Farleyense*. Hardy ferns were shown by Mr. Dyer and Colonel Graham. There were plenty of zonal pelargoniums, fuchsias, and balsams, good, from Mr. Bates, Colonel Graham, Mr. Drummond, and Messrs. Kelway and Son. Achimenes, Gloxinias, and Cockscombs, in this tent, were quite second-rate. Roses and dahlias from Mr. Keynes were wonderful for quality and freshness. Hollyhocks from Mr. Hooper, good; Asters scarcely up to the mark; Verbenas from Messrs. Dobree and Bates, excellent; novelties not numerous, but a few good things, amongst them the lovely *Anthurium Seberzerianum*, and some other less notable subjects. An extensive display of valuable plants from Messrs. Lucombe, Pince, and Co. adorned the head of this tent, and gave a peculiar richness and variety to the entrance. In the midst of this group stood a pot-plant of Mrs. Pince's Black Muscat Grape, carrying some well-ripened bunches. For this, on account of the merit of the variety, a first-class certificate was awarded. Especially meritorious were the cut flowers from Messrs. Kelway and Son, comprising many valuable and all beautiful subjects, elegantly put up; Mr. Drummond second; Mrs. Dakin third.

The amateurs' tent was not wanting in any one feature of interest contemplated by the schedule. The first prize for twenty stove and greenhouse plants went, deservedly, to J. B. Saunders, Esq., (gardener, R. Foulger), for a very handsome group in perfect health, comprising many valuable subjects; Captain Crew (gardener, G. Phillips), a good second. Mr. Saunders was again first in the class for twelve, Captain Carew second, F. W. Newton, Esq. (gardener, R. Huxtable), extra. In the class for six, the awards were, first, Mr. J. B. Saunders, second Captain Carew, extra Rev. H. T. Tucker (gardener, W. Sansom). In the class for eighteen fine-foliage plants, Mr. Saunders took the lead, Captain Carew second. In the class for exotic ferns the awards were, first, Mr. J. B. Saunders, second P. Taylor, Esq., extra Colonel Graham. A strange uniformity prevailed in all these competitions: the plants were good throughout, but Mr. Saunders's were so peculiarly bright and fresh, and comprised such thoroughly good exhibition varieties, that with them it was *Veni, vidi, vici*, inevitably, and the task of judging was almost a sinecure. F. W. Newton, Esq., sent the best *Selaginellas*—they were fine large pieces, well grown, and the varieties good; Rev. H. T. Tucker, the best *Begonias*; J. B. Saunders, Esq., the best group of Japanese Liliiums. In the class for single specimen ferns, Captain Carew took a distinguishing first place with a splendid example, second J. B. Saunders, Esq., extra P. Taylor, Esq. Gladioli poor, Goraniums scarcely first-rate; *Petunias*, from Rev. H. T. Tucker, good; Cockscombs, from J. Wood, Esq. (gardener, J. Andrews), fine; the second lot, from Rev. J. A. Miller (gardener, C. Bray), not much behind them. Cut flowers, from Mrs. Dakin, beautiful; Asters of all kinds scarcely good; Verbenas from S. Dobree, Esq., and J. H. Kallend, splendid; Dahlias and Roses, from Mr. Dobree and Mr. Bowden, excellent for the time of year.

The "ladies' tent," as it was called, was occupied with dinner-table decorations and bouquets. Save and except that the tent was a trifle too small for its fair occupants, this was one of the most enjoyable exhibitions of the kind ever held within the limits of the reporter's experience. It was literally a "fierce competition," though by the gentlest of competitors, and it was a grief to the judges that they could not award many more prizes than the schedule allowed them. There might not be much difference between the first-prize decoration from Mrs. P. Taylor and Mrs. J. W.

Shepherd's second, but after these, which stood apart from the rest, by most graceful and dignified outlines and artistic finish of colouring, some twenty other contributions claimed and obtained the admiration of a crowd, which never waned in numbers during the whole continuance of the hours of admission. Extremely beautiful was the plateau with chairs from Mrs. J. B. Saunders; and the stands selected for extra prizes, the contributions of Miss Dyer, Miss Newton, and Mrs. Sweet, were tasteful and appropriate. The style of decoration which the judges especially favoured consisted of a glass stem rising from a dish, and surmounted by a smaller dish, with the relief of a ring or oval of twisted glass to finish it. The original March pattern appears to be out of fashion, and the mirror plateau is scarcely cared for. There were three groups of fruits and flowers for the table. The first prize was awarded to Mrs. J. W. Shepherd, for a small but exceedingly neat and tasteful display; Miss Newton second, with a larger and in some respects handsomer group arranged as a pyramid, but wanting a certain finish and brightness conspicuous in Mrs. Shepherd's; third, Mrs. Groenhill, with a large and elaborate device with imitation ivy-leaves and wire branches, and other apocryphal accessories. In all three the fruits were good, and the judgment turned of course on the *tout ensemble*. Hand bouquets were as far in advance of the average as the table decorations were; in truth, we have rarely seen such a beautiful lot. Mrs. P. Taylor took first place with a pretty little convex-headed bouquet very quietly coloured, and with bits of green delicately relieving the flowers all through. Second, Miss Kate Saunders, with a hearty, consisting of bright flowers and bright fern-fronds; third, Mrs. E. Sweet, with a charming example, too conical in form to take a higher place. Mrs. J. B. Saunders presented a rather large but exquisitely finished bouquet, consisting of costly flowers, some rare orchids being conspicuous alike for their beauty and their fragrance. As this was labelled, "not for competition," the judges could only express their high commendation of its merits. Several good bouquets failed to obtain distinctions for their owners through being too highly coloured; for it must be a rule from which there should be no departure, that when a lady carries a bouquet, its splendour shall neither distract attention from her face nor render her dress unattractive. It should add to the beauty of a beautiful vision, and never justify that sarcastic passage in one of his best stories where Albert Smith said he saw a bouquet go past with a lady attached to it.

Fruits were abundant and fine. The best large collection came from C. E. Kowellife, Esq.; second, Colonel Graham. In collections of six, first, B. C. Greenhill, Esq. (gardener, A. Barge); second, E. S. Richards, Esq. (gardener, W. H. Lovell); extra, J. Carver, Esq. (gardener, J. Sutton). M. King, Esq., presented a fine pine; but other contributions in this class were inferior. Good grapes from J. W. Shepherd, Esq., J. Carver, Esq., Colonel Graham, H. Warner, Esq. Melons, every kind judged by flavour, first, J. Wood, Esq. (gardener, J. Andrews), with Turner's Green Flesh, a large fruit of the most delicious flavour; one of the best melons ever cut; second, J. Woodland, Esq. Good peaches from F. W. Newton, E. E. Richards, and J. Woods, Esqrs. Nectarines from J. C. Bowering and T. Coker, Esqrs. Apricots from F. W. Newton, M. King, and B. C. Greenhill, Esqrs. All other fruits proper to the season were shown in plenty; Cherries, from J. Dominey, Esq., Captain Shuldham, and F. Woodland, Esq., being remarkable for fine quality; and orchard-house trees bearing fruit admirably shown by Rev. E. Spryway. Vegetables, both in the open and cottagers' classes, were plentiful and of excellent quality, and some of the cottagers' flowers were first-rate, and as important pictorially as socially to the interests of this most interesting exhibition. The judges were Mr. Turner, of Slough, Mr. Dodd, of Ashton Court, and Mr. Hibberd, of Stoke Newington, in the classes for plants and flowers, and ladies' prizes. Mr. Keynes, of Salisbury, Mr. Bousie, gardener to Lord Taunton, and Mr. Randall, representative of Messrs. Lucombe, Pince, and Co., in the classes for fruits and vegetables. There was a large attendance, and the affair proved financially successful, which adds to the glory of the horticultural success. Indulgence is asked for all the shortcomings of this report. The tents became crowded before the judging was quite finished, and I did not make a single note. Fifteen days have elapsed ere an opportunity presents itself to render some account of the show, and I can only now call to mind a few particulars of the various details. S. H.

ST. CLEMENT'S AND ST. ANDREW'S HORTICULTURAL SOCIETY, NOTTING HILL.

A society bearing the above designation has been formed in the populous locality of Notting Hill, more especially for the purpose of encouraging a taste for the cultivation of plants either for adorning their windows or small gardens among the working class. The society was started under very favourable auspices, having received the distinguished patronage of the Duke and Duchess of Argyll, the Duke of Rutland, the Right Hon. the Earl and Countess of Airlie, and also of many gentlemen of influence, residents in the neighbourhood, including the Rev. A. Dalgarns Robinson, M.A., incumbent of the district church, who has accepted the office of President. The first annual exhibition was held on Thursday, August the 15th, in the St. Clement's schoolroom, Lancaster Road West, Notting Hill. Of course we consider the present efforts of the exhibitors but as the stepping-stone to the development of something better in the future. The productions on this occasion belong principally to amateurs, or, more properly speaking, cottagers, and among them were some very creditable collections, though admitting of great improvement, especially in the way of training and choice of varieties. The society has put forth every inducement in the shape of liberality, for the prizes offered and awarded were worth striving for apart from the honour conferred on the successful competitors. The building also in which the exhibition was held is admirably adapted for the purpose, being very spacious and remarkably clean.

The first object that attracted our attention as we entered the room was a very neatly constructed ornamental device, which we shall name the Temple of Flora. It was contributed by Miss Lawrence. This was placed on a table in the centre of the room. It was constructed of pillars, round which were entwined fronds of fern and other graceful foliage; the base was a wire basket filled with choice fruits; the summit was adorned with a quantity of fragrant flowers, such as stocks, mignonette, and others. But the most attractive features of this unique model were the arms of the several noble patrons woven in colours on pieces of white satin, and suspended in the shape of banners over its several quarters. The whole of the arrangements must have cost the lady considerable time and patience, as

it added much towards heightening the effect of the exhibition; and I am sure the exhibitors will feel greatly indebted to her for the interest manifested by her on their behalf. At the further end of the room, on an elevated platform, was a fine collection of tree-ferns and other miscellaneous foliated plants, some of which were at once recognized as forming part of a successful collection at the Royal Horticultural Society's exhibition at Kensington. A description of many of them and the house in which they are growing has been given in page 315 of this Magazine for the present year. They were exhibited by Mr. Burley, of the Albert Nursery, Bayswater, but not for competition. Beside them were two very interesting collections of miscellaneous plants, exhibited by working gardeners, to which prizes were awarded as follows:—1st, Mr. Hill; 2nd, Mr. Turner. Of the miscellaneous collections exhibited by cottagers, there were six exhibitors:—1st, Mr. Coombs; 2nd, Mr. Sandon; 3rd, Mr. Martin; 4th, Mr. Saddler; specially commended, Mrs. Morris and Mr. Stevens. The plants consisted principally of fuchsias, geraniums, and other kinds, which could be cultivated and preserved through the winter in the absence of a greenhouse. Though some of them were small, yet they gave evidence of care having been bestowed on their training, with the view of ensuring healthy and good bushy plants. I particularly noticed this useful feature in Mr. Saddler's collection, although only fourth on this occasion.

In the class for three scarlet geraniums there were five competitors: 1st, Mr. Sandon; 2nd, Mr. Coombs; 3rd, Miss Jordan; 4th, Mr. Poole; extra, Mr. Saddler. Of the first, all three plants were one variety, viz., Little David, a very dwarf compact variety requiring but very little skill in the training; while the second contained three distinct varieties, consisting of a good established plant of Mrs. Pollock, also Golden Chain and Lord Palmerston, equally balanced in growth. In point of flower, the first had decidedly the advantage, but as regards choice varieties and the skill required to maintain them in health, the second lot was certainly the more worthy. In the class for three fuchsias there were four exhibitors: 1st, Mr. Martin, with a well-bloomed plant of Conspicua; 2nd, Mr. Coombs, with three small healthy but even-grown plants; 3rd, Mr. Campfield; 4th, Mr. Poole. For the best window plants there were three prizes awarded, the first being withheld; 2nd, Mr. Saddler; 3rd, Mr. Horn; 4th, Mr. Campfield. Of cut flowers there were two collections: 1st, Mr. Brown, with a lot nicely arranged in regard to colour and variety. On the platform at the end of the room was a circular mound of plants in pots, but the pots were so concealed by moss and turf as to appear as if planted there. The centre plant was a fuchsia, then followed rings of yellow calceolarias and other bedding plants, and lastly an edging of white lobelia; on either side were wire baskets containing ferns, and in the rear were two plants of that very old favourite, *Campanula pyramidalis*. These were so bent as to form an arch, thus giving a very pleasing and striking effect to the whole. I am not able to say who contributed this pretty group, as I did not observe any name affixed to it. For two ornamental devices, 1st, Mr. C. Shatlock; 2nd, Mr. Shatlock.

Of miscellaneous subjects, there was a most interesting collection of dried grasses, numbering 134 varieties. These were exhibited by Mr. Turner, a working gardener. In collecting and arranging them they showed evidence of a very persevering and intelligent mind. The same exhibitor sent a stand of not less than thirty-four varieties of wild fresh cut flowers in full bloom. Both collections had the name affixed separately to each variety.

There were also prizes awarded to working men for the best-cultivated flower garden. I had not an opportunity of seeing them, therefore am not in a position to offer any comment, but record the prizes in the order they were given. 1st, Mr. Darsey; 2nd, Mr. Stephenson; 3rd, Mr. Palmer; 4th, Miss Jordan; 5th, Mr. Poole; extra, Mr. Mascall. There were three scales of charges of admission during the day, so as to afford all classes an opportunity of uniting to benefit the society; and I am delighted to say that there was a large attendance of working men with their wives and families during the evening. The performance of an excellent brass band did much towards enlivening the meeting. The whole proceedings were concluded by the rev. President giving the successful exhibitors their prizes, accompanied with some general remarks on the good that must accrue to all who endeavour to profitably use their leisure hours.

JNO. F. McELROY.

ALEXANDRA PARK WORKING MENS' CLUB.

The second annual trip of the Alexandra Palace and Muswell Hill Estate Working Mens' Club took place on Monday, August 12th. The weather being delightfully fine, upwards of three hundred workmen, accompanied by their wives and sweethearts, were (by the kindness of the Great Northern and the London, Chatham, and Dover Railway Companies) conveyed by special trains to that most suitable of all places for spending a happy day, the Crystal Palace. This club is organized for the purpose of supporting sick members, paying doctors' fees, and burying the dead. Every workman becomes a member, and contributes 4³/_d weekly, in return for which he receives 12s. per week when he is unable to work, his doctor's fees are paid for him, and in case of death £5 towards funeral expenses, and £2 10s. towards the funeral expenses of a member's wife. This club has now been in existence over two years, and enough money has been saved annually to pay for the trip to the Crystal Palace, provide a good dinner, and a day's healthy exercise and rational recreation. The dinner was provided by Messrs. Bertram and Roberts, and was served in good style; the men seemed thoroughly to enjoy themselves, and there is great credit due to Mr. M'Kenzie for the promotion of such an institution as this. I should like to see others doing the same thing, especially where they have a number of men under them, as is the case at the Alexandra Park. I have twice enjoyed the annual dinner of this club, and I can say that the whole affair is a pattern of able organization and personal decorum. The chair was taken by Mr. M'Kenzie, supported on the right by the Rev. Mr. Webster, of Horsey, and on the left by G. E. Webster, Esq., of Sydenham. After dinner, the usual loyal toasts were given. G. E. Webster, Esq., proposed success to the Alexandra Park and the Crystal Palace Companies. He spoke in the highest terms of the Crystal Palace, and the public benefit it had proved to be in furnishing instructive recreation to the people. He sincerely hoped the Alexandra Park would meet with equal success, and even rival the Crystal Palace. The Rev. Mr. Webster proposed the health of Mr. M'Kenzie and family, and spoke in the highest terms of that gentleman, especially in respect of the way he is carrying on the works of the Alexandra Park, and the good he does in providing such a treat to the men. He had pleasure in being there last year, and he was glad to meet them again this year at the same place; but he was sorry there were only

three hundred men instead of four hundred; but the reason was, the remainder had left last week to go to harvest work, and for that he thought they might be spared for the good of themselves and the country. He gave the men an invitation to come every week to the meetings at Hornsey, where he had the pleasure of meeting many who were now present, and still hoped he should see more of them; and if there was not room for them all, he would hold the meetings in the open air. Mr. McKenzie returned thanks. He spoke in the best terms of his men, and the good he had seen arising from the club, and as long as he had to do with men he should always try and provide for the sick and needy, and for their comforts, especially while the men behaved as they had done at this and the previous meeting. He went on then to tell us the state of affairs of the club, a subject which of necessity interested all present.

B. S. W.

AUTUMNAL ROSES.

The question of a second rose show on a large scale, and later in the season than those already held, is of great interest and importance, not only to amateurs and nurserymen who have small collections or late soils, but also for the real improvement of the flower itself in one of the most valuable qualities it can possess. Every one desires to obtain as much as possible from his garden, whether fruits or flowers, and, as far as the subject of this paper is concerned, the greatest progress has usually considered to have been made in the direction of the hybrid perpetuals or continuous blooming kinds. Yet, from the periods at which the shows are at present fixed, many fine varieties are never seen on the tables, and are in consequence dropping out of repute and cultivation till it will be too late to recover them. Indeed, as far as rose shows are concerned, from the dates at which they are usually held, mere summer roses would answer every purpose, as they afford neither test of nor encouragement to the development of one of the most valuable properties the rose can possess, and for the want of which summer-blooming roses only have been almost entirely cast aside. Many varieties which are now recognised favourites with exhibitors are in ordinary seasons virtually but once-flowering kinds, such as Madame Boll, Madame Hector Jacquin, Madame Boutin, and a host besides; while a numerous list of others could be given which are never completely in season in time for the earlier shows, and which are seldom therefore seen in true character in public, to the loss of their deserved reputation as well as to uninitiated cultivators, who are too often simple enough to believe the names in prize lists indicate the best varieties to grow. The opportunity afforded by the Crystal Palace Autumnal Show of fruits and flowers ought not to be passed by without a strong effort being made by all real well-wishers to the progress of the rose to inaugurate a rose-show in connexion with this September exhibition. The fine weather we have recently had will have tended to produce an unusual quality of the autumnal kinds, which ought to be an additional reason for making the attempt.

If we analyse the productions of our rose grounds, it will commonly be found that the property of frequent blooming lies chiefly in the kinds partaking of China or Bourbon origin, the term China including the Teas and certain of the Noisettes. The twelve varieties most to be depended upon for flowers during the season, combined with quality, are Gloire de Dijon,—especially if the long shoots are stopped at three or four feet, almost every lateral will then produce a flower; Souvenir de la Malmaison (B.), still the most beautiful of the tinted whites, and exquisitely perfumed; Safrano, Madame Falcot, Madame Willermoz, Devoniensis, Vicomtesse de Cazès, the last five are Teas, and require more or less protection during winter, especially the last; Mrs. Bosanquet (C.), though it appears to have some affinity with Malmaison; Emotion (B.); with H. P.'s General Jacqueminot, Jules Margottin, and Victor Verdier. Of the last class, Anna Alexieff, Madame de Cambacérès, most adaptable of roses, and Madame Domage, one of the largest and sweetest, must be added. All the above are show flowers, as well as such admirable adjuncts to the borders or rosery. Among the Bourbons, as previously intimated, a wide range of autumnal roses would be met with, many of which now only exist in old catalogues, and perhaps in some remote country gardens which the spirit of innovation—not always the spirit of improvement—has not divested of old favourites. Aurore du Guide, Armosa, Apolline, Bouquet de Flore, Dupetit Thouars, Le Grenadier, Paul Joseph, Prince Albert, Molière, Souvenir de l'Arquebuse, Empress Eugénie, if not large enough for the taste of the present generation, have not been surpassed in their line, amongst which symmetry of form is not the least feature. Add to them the following, of somewhat later date: Paxton, Victor Emmanuel, Modèle de Perfection, Baron de Noirmont, Rev. H. Dombrain, Catherine Guillot, the last four classed by some growers under the more novel head of Bourbon Perpetuals; and the cultivator will have a nice collection of compact flowers, free in the fall of the year, if not so large as the fashionable monstrosities of the tables, whose coarse hulk should be a disqualification instead of a beauty and recommendation.

The common China and its varieties is a persevering exhibitor of its pretty pink blooms, early and late, and should be copiously distributed in every garden. The Teas also are usually free-flowering kinds where the climate will allow them to be grown in the open air.

The Noisettes are late, but not very perpetual, blooming in clusters, and suitable for walls.

The best of the twice-blooming Hybrid Perpetuals, for very, very few of them go beyond this, will be found in the following list: Hybrid Perpetuals, alphabetically arranged—Alfred Colomb, likely; Admiral Nelson, Auguste Mic, for good climates; Baronne Prevost, Beauty of Waltham, Charles Lefebvre, Comtesse Chabriland, Comte de Nanteuil, Colonel Cambriels, Comtesse Kergolay, Crimson Perpetual (D. P.), Duchess of Norfolk, Doctor Julliard, Duchesse de Morny, Eugène Verdier, Eugène Appert, François Lacharme, Géant des Batailles, Gloire de Chatillon, Henry IV., Impératrice Eugénie, Jacques Lafitte, old; Jean Goujon, Jean Bart, John Hopper, La Brillante, La Fontaine, La Reine, La Ville de St. Denis, Louise Peyronny, Le Rhône, Louise Darzens (P. N.), La Reine de la Pape, fit only for borders; Madame Alfred de Rougemont (P. N.), Madame C. Crapelet, Madame C. Wood, Madame C. Joigneaux, not always; Madame Domage, Madame E. Vilmorin, Madame Freeman, Madame Souppert, Madame Bruny, Madame J. Daran, Madame Knorr, one of the most certain; Madame Pierson, an incurved rose; Mdle. T. Appert, Mdle. Bonnaire, Madame V. Verdier, Mareschal Suchet (Guillot's), Marie Boissée, Marcella, not sufficiently proved; Marguerite St. Amand, Monsieur Montigny, Mrs. William Paul, Mrs. Rivers, Pavillon de Pregny Parmentier, Pierre Notting, Prince C. de Rohan, not always; Prince de Porcia, Princess of Wales (W. Paul), Prince Napoleon, Pius IX., Rosa Mundi, Reine des Fleurs, Red Rover (W. Paul), Reine de la Cité, Reine de Castile, Sophie Coquerelle, Souvenir de Leveson-Gower, Sénateur Vaisse, Sœur des Anges, where locality suits; Triomphe de la Terre des Roses, Triomphe des Beaux-Arts, Triomphe de Caen, Triomphe de Paris, Triomphe d'Angers, Vainqueur de Solferino, Virginal, Vicomte Vigier, William Paul, Xavier Olibo, not sufficiently certain. Of course the previously-named kinds must be included in this list. Noisettes are mostly late-blooming roses, and none are preferable to Maréchal Niel, good Aimée Vibert, Jean d'Arc, Ophir, and the once favourite rampant grower, but unfortunately too tender, Jaune Desprez; the blossoms of this are as beautiful as curious in their mixture of colours, and are also remarkably sweet. It is not pretended that the above is a perfectly exhaustive enumeration, but it is copious and reliable, being the result of actual experiment and research.

It cannot have escaped the notice of the observant horticulturist how much sooner the foliage of deciduous trees and plants turn yellow and fall in the neighbourhood of large towns. The same causes affect the rose, which is consequently much less disposed to bloom a second time in such localities than in regions where a purer and more rural atmosphere prevails.

Before quitting the subject, it will be desirable to point out that improper treatment or neglect will speedily reduce a free-flowering to a sparse-blooming kind. Those who wish for a second crop of roses must behave to their plants liberally, feeding them well, and flooding them plentifully in dry weather. Three or four times before August they should have a couple of gallons of liquid manure each, thoroughly saturating the soil round the plants, but not touching the collar; the soil would be better previously loosened with a fork. Attention should likewise be paid when cutting the flowers to go back to a promising eye, indicating by its form a future bloom-bud. A succession of flowers may also be procured by varying the time of pruning in the spring. Annual or biennial lifting in November should also form part of the course of culture of all who desire their roses to bloom satisfactorily in the autumn, always renewing the soil as well as enriching it during the operation, *i. e.*, giving fresh earth as well as manure. The process will also afford opportunity for root pruning—an important thing. A spadeful of clean crushed bones thrown into the hole is a valuable and nourishing addition. I have been told by one who practised it, that in a short period the roots would run amongst them in a mass of fibres, which enabled him to lift and replace them with great ease and security.

W. D. PRIOR.

London Road, Clapton.

POT CULTURE OF THE GLADIOLUS.

The season has arrived when the most of us are beginning to think of selecting our bulbs, especially for growing in pots. Lilliums, Hyacinths, Tulips, &c., have each their place assigned for the above purpose; but very few make choice of the Gladioli for pot culture, considering that they succeed best when grown in beds or borders, and certainly their effect when so grouped and in flower is strikingly grand; but let me advise those gardeners who have to maintain a succession of bloom in the conservatory throughout the year, now they are ordering their bulbs, to procure some roots of Gladiolus for growing in pots. If they have not previously adopted the practice, they should now select them for flowering during next summer; and, if they succeed, I am certain after that they will be only too anxious to extend their culture in the future.

Having, in the early part of this year, a surplus stock of Gla-

diolus Brechleyensis, floribundus, and one or two other varieties, for which I had no room in the borders, the thought occurred to me that I would see what they would do in pots. The roots of Brechleyensis were very large and fine. Of this variety I planted three in an eleven-inch size pot. The soil which I used was good stiff yellow loam, mixing with it about a fourth of decayed manure. In planting them I did not cover the crown of the root with more than an inch in depth of soil; but I potted them very firm, taking care to press the soil well round the bulb. After this they were placed in a cold pit; and as soon as they had grown somewhat, and the weather would permit, they were removed to a spot out of doors, and abundance of water given them as they needed it. The great object of the cultivator should be never to let them suffer for lack of moisture to their roots, otherwise the foliage will become brown and unsightly. Thus treated, my bulbs have sent up splendid spikes of flowers, and the effect has been gorgeous, the colour of Brechleyensis being a rich vermilion-scarlet, contrasting finely with the soft but delicate white and rose colour of Floribundus, another beautiful variety. Pot Gladioli are the more useful because they come in when the showy pelargoniums and other early summer subjects are ceasing to attract admiration.

JOHN F. McELROY.

PLANTS USED FOR DECORATING WINDOWS IN PARIS.

I send you a few notes upon the principal plants which serve for window decoration in Paris. Among these plants the *Palms*, without doubt, occupy the most important position. I give below a list of those which are most generally used, not only because of their rustic appearance, but also on account of the very moderate price at which they can be obtained.

Chamærops humilis and *excelsa*.

Corypha Australis.—This plant, although now but little known, is destined in a short time to occupy a foremost place in the decoration of apartments, where it makes itself conspicuous by its peculiar beauty, and the number of its leaves; it is, I believe, the most rustic in appearance of all the Palms. The *Cocos coronata* and *flexuosa* are very elegant, and produce a charming effect. *Lantana borbonica* is certainly the most *recherché* plant of this family, and is valued as much for the beautiful green of its leaves as for its general rustic and elegant appearance.

Phoenix dactylifera, *leonensis*, and *reclinata* are also very much sought after, and are highly esteemed.

Areca alba, *lutescens*, and *rubra*.

The following list of *Palms* could also be used with great advantage in the decoration of apartments; but their high price and great rarity cause them to be not much known, although they accommodate themselves to the atmosphere of rooms as well as any of those previously mentioned.

Areca sapida, most of the species of the genus *Caryota*, *Chamædorea amazonica* and *elatior*, *Chamærops palmetto*, *Elais Guinensis*, *Euterpe edulis*, with its finely-serrated and very graceful foliage; *Oreodoxa regia*, young plants of which are very frequently used; *Phoenix pumilis*, *Rhapis flabelliformis*, and *Thrinax argentea* and *elegans*.

Next in importance to the *Palms* we must place the *Dracænas*. Those which are the most frequently noticed are *Dracæna Australis*, *cannæfolia*, *congesta*, *indivisa*, *indivisa lineata*, *rubra*, *stricta*, *terminalis*, and *umbraculifera*. Those most easily managed, and therefore the most popular for window ornaments, are *Dracæna congesta*, *rubra*, and *terminalis*.

Pandanus utilis, *Neudermerschi*, and *Javanicus variegatus*; *Cycas revoluta*, and the different varieties of *Aspidistra*, occupy also a very important place in the decoration of apartments.

The plants composing the following list, although very rural and elegant in appearance, are less sought after and cultivated than the preceding ones, because they are more difficult to manage as window plants, and require considerable care and attention. They are more suitable for frames and cases, and may frequently be met with cultivated in that manner.

Several species of *Aralia*, more especially *Aralia Sieboldii*; *Bambusa japonica variegata* and *B. Fortunei variegata*; the different varieties of *Begonia*; most of the *Bromeliaceæ*; *Caladium odoratum*, for winter decoration, and the other species, with their beautifully-spotted and mottled leaves, for the summer; *Carludovica palmata* and *plicata*; *Croton pictum*, *pictum variegatum*, and *discolor*; *Curculigo recurvata*; some species of the genus *Dieffenbachia*. The *Ficus elastica* is a very elegant plant for a window ornament, and some years ago was very much employed for that purpose; but since it has become somewhat common *Ficus Chauvieri* has been substituted for it in many places. *Isolepis gracilis*; *Maranta zebra*—this is the only species of *Maranta* suitable for cultivation in apartments, as all the others speedily succumb to the hot and dry atmosphere inseparable from a living room. Several species of *Musa* are favourites, but principally *M. discolor* and

M. rosca; *Musa cnscte* is particularly suitable for window culture, but it is still so scarce, and of such a high price, that it is but seldom met with. *Pandanus amaryllifolius*; *Philodendron pertusum* was much sought after during the past winter, and has in most places thrived so well that it has given general satisfaction. Several varieties of *Pencenctia* are very suitable for rooms, and produce a very beautiful and graceful effect when grown in suspended vases or baskets. *Rhopala corcovadensis*: this plant exhales a somewhat disagreeable odour, but is nevertheless very much sought after, on account of its very elegant and graceful appearance during the development of its young leaves. *Tradescantia discolor*, *Phormium tenax*, *Rhododendron*, *Camellia*, *Grevillea robusta*, *Euonymus*, *Aucuba*, *Bonapartea*, *Agave*, &c., &c.

The family of Ferns, although classed among plants with delicate tissues, and having a great dislike to dry hot atmospheres, nevertheless furnishes numerous examples, which, with careful management, add very much to the beauty of apartments. Thus I have very frequently remarked several species of *Adiantum*, which, wherever they can be preserved in good health, produce without doubt a most ravishing effect. *Pteris argyrea*, *P. cretica albo lineata*, and *P. serrulata variegata* also produce a very fine effect, with their prettily-marked foliage. *Alsophila Australis* and *Balanium antarcticum* are also sometimes employed for decorative purposes in rooms of large dimensions, where their magnificent appearance never fails to produce a very imposing effect.

All kinds of plants bearing flowers have paid their tribute to the ornamentation of rooms, from the humble mignonette, upon which the patient sempstress loves to turn her weary eyes, to the magnificent orchid that, with its brilliant colours and fantastic forms, fills with grace and beauty the apartments of the affluent.

Until very recently, I had believed that orchids would never flourish if taken from the greenhouse; but a gardener of my acquaintance has introduced them while in bloom into a drawing-room with perfect success, the plants not having suffered in the least by the change of atmosphere. These orchids were, if I remember rightly, species of *Catleya*, *Vanda*, *Aerides*, &c.

Paris.

A. CHANTIN.

ON DEEP CULTIVATION.

Every feast leaves its crumbs, and some which I collected on the spot I now venture to send to you. Were we to examine the depth to which the roots of many of our cultivated plants will penetrate a loose open soil in quest of food, we should be less sceptical as to the advantage which deep cultivation affords to the roots of plants. The market gardeners around London trench often and deeply, not only to change the surface, as some suppose, but to allow the roots of their crops to range as deep as they please, and without this assistance the enormous crops of first-rate produce they take from the land could not be obtained. If deep cultivation is requisite in the rich and deep alluvial soils of the Thames valley, how much more so is it on poor and shallow soils, which afford comparatively only a limited pasturage for the roots of plants!

It is true, gravelly and rocky subsoils are almost beyond the reach of improvement, as the expense of breaking up the substratum would, in most instances, be too great to pay. But this is not always the case, for I have seen the brashy subsoil of some localities broken up with good results, as well as some gravelly subsoil, particularly where the layers of gravel are thin, and mixed with clay or ferruginous matter, rendering them impervious to water as well as to the roots of plants. By breaking through this crust, so as to admit a free passage for the water, a marked improvement follows. Clay subsoils, however retentive, are capable of being reclaimed; but this is a work of time, as all you can do after thorough drainage is to break up the clayey bottom to the depth of twelve or eighteen inches, according to its nature, each time the ground is dug or trenched. This bottom when forked up should be kept as open as possible, which will facilitate the passage of water through it, and the salts and ammonia carried down by the rains from the manuring, &c., of the upper soil will in time reduce its tenacity, assisted by the decomposing action of the air, which will now have better access to it; and, in a few years, by practising this you will find your land gradually increasing in depth and productiveness.

Many calcareous and slaty rocks are likewise capable of improvement when broken up and exposed to the action of the weather, and when shallow soils rest on these descriptions of rocks, by all means break up a stratum of it yearly below the top soil. Many hard compact marls of the red sandstone and lias formations are as unfavourable for the growth of plants as rock or gravel, and yet when broken up, and exposed to atmospheric influences, they make fertile soils capable of producing every kind of crop. To obtain a sufficient depth of soil for the roots of vegetables to penetrate is one means, and a great one, of increasing their produce. Plants growing in soils made open for a considerable depth are much less liable to suffer in dry weather, as their roots are in a position to obtain moisture at a lower depth, and hence the suitability of deep soils for summer crops; the same soils are likewise warmer in winter. A soil from which the water passes through freely can never be very damp, and relatively never very cold; nor are they so dry in summer, for this reason—the action of the sun's rays on the surface soil causes the moisture contained therein to be given off by evaporation, and this produces an upward action of the moisture contained in the soil below, to supply that which has escaped by exhalation from the surface. We shall find, then, that, in proportion to the power of the evaporating process on the surface, there will be a corresponding rise of watery particles through the entire mass of soil below. This will positively keep the soil moister, because it is more open and porous than a shallow soil with a compact subsoil, which would obstruct the progress of moisture from below, at the same time as it prevented its escape downwards. By all means, then, for vegetables have a mass of soil, if practicable, from two to three feet deep, sufficiently open to admit air and water to pass freely each way when needed.

Fig. 1.

CONSTRUCTING A VINERY.—No. II.

When I closed my last article on this subject, I did not intend to give plans of vine borders, thinking that a plain description would suffice. But as some friends think they would be serviceable to inexperienced cultivators, I very cheerfully comply with their wishes; and I here give such outlines as will enable any of my readers to construct a vine border, whether in a favourable or unfavourable position. And here perhaps some general remarks may be necessary to a proper understanding of my views on the subject. In the first place, it will be seen that I am an advocate for placing the border above the ground level. This remark I mean to refer

those who made it. I do not mean to say that the water so drawn to the bottom of the border lies there in a stagnant state, as, if constructed as I have here shown, the drain would carry it away (at least for a time). What I want to show is, that when borders are so made, there is a much greater quantity of water passing beneath the roots of the vines than many suppose, and every sensible cultivator will understand that it must have a tendency to render the soil cold above; and when the bottom of the border is concreted or paved, and surrounded with a brick-wall, then no harm can come to it, as the water cannot affect the border. But as the majority of borders are only surrounded with the natural soil of the

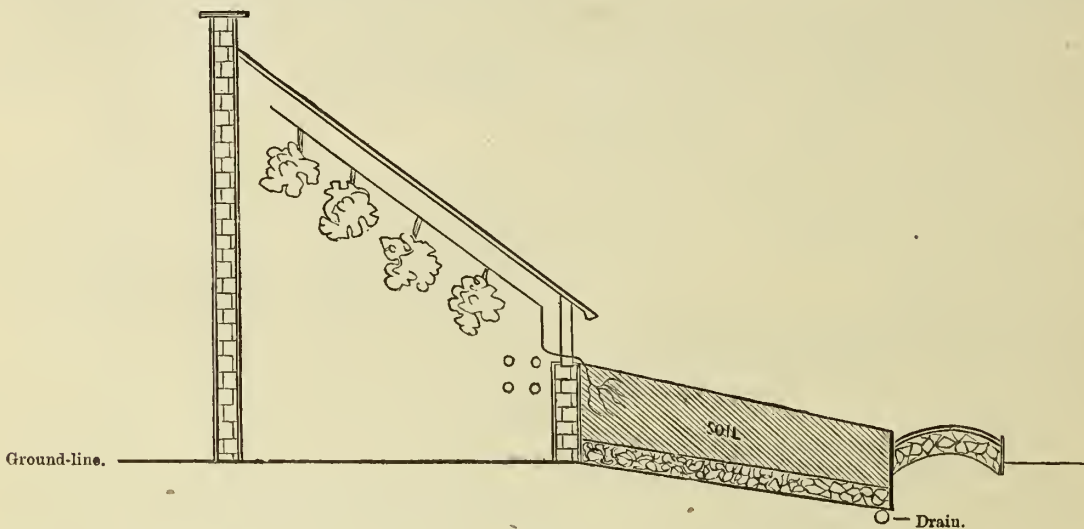

Fig. 2.

to the majority of cases. It is not strictly necessary in some few instances, and this last remark only applies to those exceptionally favourable soils and very dry situations. There are many ungenial soils and cold situations where it would be very unwise to place the border on a level with the surrounding surface of the garden, as the drainage provided for the roots of the vines serves also to drain the surrounding grounds, so that the vine border actually serves as a receptacle for a much greater space that ever was anticipated by

place, we must deal with it in the surest way possible that is likely to lead to success, and this is best secured by placing the bottom of the border on a level with the surrounding surface, or, at the most, only a few inches below it at the point farthest from the house, as shown in figure 2. I have the greatest possible objection to borders beneath the surface in cold soils, unless they are concreted at bottom and surrounded with a brick-wall up to the level of the soil, because after some ten or twelve years' standing the

Fig. 3.

drainage gets choked up, and the border ultimately becomes sodden and sour. When this takes place, the roots of the vines work less freely, consequently they begin to show signs of weakness, until they get so bad that they are condemned to removal, and all this while the cultivator is perplexed and disappointed, and is continually hunting up excuses to account for the unfavourable condition of his vines. That this is the cause of many failures with vines that for a few years were promising I have not the slightest doubt.

Another consideration in favour of borders above ground is that, lying drier, they are consequently warmer, and are at all times more manageable. They may require more water in dry seasons,

Fig. 4.

but it is much better for the vines to have to give them an occasional soaking than to have them constantly surrounded with a damp cold soil.

I am no advocate for restricting the roots of a vine that is not forced early, unless it be in an unfavourable soil or situation. And there are many positions where the roots may ramble for many yards without injury, but, on the other hand, collecting a more abundant amount of sustenance, which necessarily adds to their fruitfulness and vigour. But in every case the border should be concreted at least ten feet wide, the whole length of the house, and beyond this it is not likely that the roots will come to harm.

It is almost impossible to say to what distance the roots of a vine will travel in search of food, when there is nothing to impede its action. I well remember, when at Moor Park, finding the roots from a large old vinery some twelve or fifteen yards distant, and the vines in that house were not surpassed in fruitfulness and vigour by any in the same county. There are very few good grape-growers but could tell us of similar instances. Therefore I maintain it is not desirable to confine the roots to a limited space, when the surrounding position is dry and the soil favourable for their extension. In every case which I have seen of old houses remarkable for their productiveness, the roots of the vines have had unlimited room for extension, and I am not afraid to hazard an opinion that a healthy vigorous vine, fifty years old, will extend its roots, if the surrounding soil be suitable, the same number of yards.

Turning our attention now to the sections of houses and borders shown, we find figure 1 specially designed to suit a position that is cold and the soil stiff and damp. The border, as shown, is made upon the surface; the drainage placed upon a concreted bottom, with the drain to take away the water. If the soil and position is cold then the roots should be confined, and the border kept in a fertile state by rich surface dressings.

Figure 2 is for a similar position. I merely give this section to meet the case of those who may object to a raised border, or where the position will not admit of the border being all above ground.

Where this plan is adopted, it will be still more important to confine the roots in an unfavourable soil.

Figure 3 is applicable in any case with the roots divided between the inside and outside. This is a very desirable plan for an early house, and gives any one who may wish to try it an opportunity of growing vines upon two sets of roots. Figure 4 is a chambered border, which can be heated either by a flue or hot-water pipes. The three piers supporting the floor being composed of bricks let in pigeon-hole fashion, to allow the heat to circulate evenly, the floor should be supported either by slate or stone slabs, leaving a vacancy of about an inch between each two, to allow the heat to ascend into the soil above. In this case, eight inches of

drainage and two feet of soil will suffice, as the surface of the border will require to be annually enriched.

Figure 5 is given to meet the case of a correspondent who has only a space of sixteen feet wide, on which he wishes to put up a span-roofed vinery, a span being essential to be in character with his dwelling-house. Similar inquiries are often made by those who have small places. I therefore hope the rough outline here given may be useful to many. The roots are all inside, with the border considerably raised to meet the case of our correspondent. But there is no reason why it should not be some twelve or fifteen inches lower, if desired. I may add that many amateurs seem to forget that vines can be grown with their roots inside. Here I must close this article, leaving the remarks I had intended to make on the construction of the border until another opportunity. J. C. CLARKE.

Fig. 5.

were taken away, when the bird forsook its nest in the beech, and again commenced building over the door, in the place it had first chosen. The nest was again destroyed, and two slates placed over the spot. The bird contrived to throw down one of the slates from a slanting to a horizontal position, and then began to build upon it. The nest was again destroyed, and the three stones replaced, and kept there a fortnight, after which they were again removed, and directly they were taken away the bird again began building. The nest was subsequently destroyed several times in succession. The bird was twice driven away by a towel being thrown at it. A stone, wrapped in white paper, was placed on the ledge to intimidate it, but the fly-catcher still persevered, completed a nest, and laid an egg in it. On hearing the circumstances, I directed that the persecution of the poor bird should cease, after which it laid two more eggs, hatched all three, and successfully brought off its brood.—“The Birds of Norfolk,” by Henry Stevenson.

PERTINACITY OF BIRDS.—A spotted fly-catcher (says Mr. Gurney) began to build a nest over the door of the lodge at the entrance of my grounds. The woman who lives in the lodge destroyed the commencement of the nest. Every day for a week the bird placed new materials in the same place, and every day the woman removed them, and at the end of a week placed a stone on the ledge, which baffled the fly-catcher's efforts at that spot; but the bird then began building at the latter end of the ledge, from whence it was also driven, and three stones being then placed on the ledge, the bird relinquished its attempt, and commenced a nest on a beech-tree opposite, which it completed, and laid two eggs. When the bird was thus apparently established, the stones over the door

HORTICULTURE IN FRANCE AND AT THE GREAT FRENCH EXPOSITION.

(FROM THE TIMES CORRESPONDENT.)

French horticulture is, generally speaking, less advanced than our own, but in some respects it is far superior. Its best features were but very imperfectly represented at the Exposition, and therefore, in attempting to point out such of them as are best worthy of adoption with us, I shall not confine myself to the reserved garden in the Champ de Mars, but discuss the horticulture of the country generally, having had good opportunities of studying it. This course is the more desirable, in consequence of the Commissioners having refused to allow the Imperial Horticultural Society to manage the gardening part of the Exposition, and therefore many good exhibitors have not taken part in it.

I will first touch upon the most elegant phase of the subject—plant decoration in Parisian houses. Here the French are far before us. In many British houses plants are so ill arranged, and so very ill selected, that we must not be surprised to find a good many people dispensing with them altogether as an ugly and expensive nuisance, though they are, when well selected and tastefully disposed, the most refreshing and desirable of all indoor embellishments. Instead of employing a number of ordinary flowering plants as we do, they use a great number of small graceful palms, and other plants distinguished by striking or elegant habit, or by leaf-beauty. There are obscure nurseries about Paris in which you may find thousands of handsome young palms, *Dracænas*, Screw pines, the New Zealand flax, aralias, ficuses, and numerous other plants distinguished by beauty of form. The British gardener still adheres to his scarlet geraniums and dumpy graceless plants, generally excluding a particle of grass or verdure. Of course, we must change all this if we are to fully enjoy our plants and gardens. Not only do those palms, &c. furnish the finest effects, but they, not depending on flowers for their attractions, may be used at all seasons, and have generally a strong and leathery texture of leaf, which enables them to thrive very much better in the dry air and dust of a house than the flowering plants which we usually employ so much. There is scarcely a decent house in Paris in which you may not see the refreshing verdure of palms, comparatively diminutive it is true, but in every line as beautiful as when fully developed in their native wilds. Of course the dwarf flowering plants may be employed with these palms, and far more effectively than if arranged alone. When the French decorate a house for special occasions, the utility of their quantities of "fine-leaved" plants is seen at a glance. They produce such effects with them as those who have not seen the *Hôtel de Ville*, or any large Parisian house decorated for a fête, can have no conception of. Even on occasions when we can command plants of light character, we frequently place them so ill that the artificial conditions under which they exist with us are suggested at a glance. At the annual reunions of the Linnæan or Royal Societies, where they get the best plants from Kew, you may see a fine subject with its ugly pot or tub more conspicuous than its head; while the French, on the other hand, always arrange the plants in tasteful groups, in which you see a sufficiency of gay and choice flowers among the nohler materials already spoken of, and not a trace of awkwardness, in consequence of the pots, tubs, &c., being plunged in banks of fresh moss. A due proportion is carefully preserved in all parts; they line staircases with a border of dwarf but still graceful things, and in wide halls with pillars they place tall palms with great arching leaves and drooping leaflets, which meet overhead and make the scene more beautiful than anything of the kind we ever see in England. The effects often produced in this way in Paris are, indeed, superior to anything seen at our flower shows, in consequence of the pleasing mixture of all the materials, and the charmingly natural effect which results from it. However, it is as permanent indoor ornaments that the plants named deserve most attention in the British isles.

To turn to the edible department, we have first to admire the magnificent apples and pears which the French grow. These are often to be seen in Covent Garden, and at some of our great fruit shows. During the past spring, specimens of the *Calville Blanche*, *Reinette du Canada*, and other fine apples, were sold in Paris fruit-houses for as much as two and three francs apiece. It may well be imagined that apples which could command such a price must be very fine, and such was the case. In point of flavour or external beauty they were such as we never produce by the ordinary way of growing apple-trees. The choicer kind of pears may be grown in the same way and with equal success, so that planting pears with the philanthropic view of supplying ones' heirs and posterity generally is not now so praiseworthy, or, at all events, so necessary a practice as it used to be. They adopt it to gain increased light and warmth, and we have the same wants in a somewhat greater degree, even admitting that the climate of a great part of France is very like our own and much more disagreeable than we generally suppose it to be. The way they induce the apple to bear such fine fruit is by training it as a single shoot along a wire supported at about one foot from the ground. They graft those little trees on a stock called the "Paradise," which induces a dwarf habit and early fertility, so that trees on it bear fine fruit at two years of age. The single shoot which forms the tree is kept closely pinched to its wire, the fruit it bears is at all times freely exposed to the sun, and it is perfectly under the command of the cultivator, who thins the fruit so as to allow of a large development. These *cordons* are trained round the borders of many French gardens as an edging to the vegetable quarters, but the method best suited for the English garden is that of having several lines stretched along a cosy warm border, fully exposed to the sun, and placed at a couple of feet or so apart. They are thus grown to a considerable extent in the Imperial kitchen garden at Versailles. Such an arrangement would be capital for the choicer kinds of dessert apples, our ordinary wants being best supplied from trees allowed to grow naturally, and well thinned out to allow of a free supply of air and light to the fruit. They grow the pear in the same way, and with an equally good result, but it is also very extensively grown as a pyramid.

The peach is also grown to great perfection, and chiefly for the Paris market at Montrouil, a few miles east of Paris. Near that town a large surface of land is noted over with white walls, enclosing small squares of ground, and against those walls the peach-trees are trained. Some of the gardens are very interesting, and exhibit specimens trained in a singularly perfect and beautiful manner. The celebrated Napoleon peach tree is one of them, and is an interesting example of their complete mastery of the tree. It is simply a single specimen trained so as to figure the name "Napoleon" very largely on a white wall, one branch going to form each letter. Two great shoots are trained around the letters so as to enclose them with a border. The

tree bears a capital crop, and is an excellent example of what may be done by skillful training. There are many other shapes, some of them equally interesting, but of course these curiosities in training are more for ornament than use, though they bear as well as the simpler and more natural shapes. The soil is a calcareous loam, but there is nothing either in the soil or climate of the place which is so effective as the special and careful training and culture, and undoubtedly quite as good a result might be produced with the best of our open-air fruits in the warmer and more genial parts of England and Ireland.

A French gardener is capital at a cauliflower or the materials for a salad, but it is at asparagus that we find him great. One of the first things that strikes the English visitor to Paris is the great excellence of this dainty herb for many weeks in spring. The student in the Latin Quarter, who pays a couple of francs for his dinner, enjoys it longer than many an English country gentleman with a bevy of gardeners. A plate of it at any of the great establishments (*de bouillon*) is very nice for 2½d., while its aldermanic proportions, polished ivory shaft, and rosy bud at Philippe's, Durand's, or any of the first-class restaurants in Paris, is truly admirable. In France it is very much more extensively grown than with us, and everybody enjoys it, so that they have for a long time in spring and early summer what we may term the season of asparagus. For the Paris market it is grown to the greatest extent in the valley of Montmorency and at Argenteuil, a town on the Seine, a few miles north of Paris. About the latter place several thousand persons are continually employed in its culture, and thence were sent the specimens which were so successful and so much remarked at the Exposition. Their system of cultivating it is directly opposite to ours, much more sensible, and equally or more adapted to British soil and climate. Instead of planting on a bed or on the level, as we do, they plant in a shallow trench. Instead of crowding the plants together, as we do, they place each quite distinct, so that it has full room to become a strong and vigorous plant; and instead of leaving them to nature, as we generally do, when once planted, they continually exercise a watchful care to preserve them from breakage with wet winds by staking, to replace all delicate plants, and refresh them every year with a little manure. About Argenteuil it is very much grown among the vines, each single plant or stool standing 6 ft. or 8 ft. apart in every way. But the special way of growing it is best suited to our own wants, and of the several ways adopted the best is that of planting in a trench about 8 in. deep, the ground having been previously prepared, and the contents of the trenches thrown up between each row. They place the plants at about a yard apart in these little trenches, and every year afterwards they remove the earth carefully to the roots, spread a couple of handfuls of rotten manure over them, and cover up again. Small crops, such as lettuces, early potatoes, &c., are grown on the little ridges of earth between the trenches, and in some cases a wide trench with two rows of plants is employed. When the plants get well established and old they gradually grow up, and the little ridges being gradually added to the annual dressings, the surface becomes level, or nearly so. In a word, by planting below the surface they allow for and encourage the natural tendency which the plant has to rise, develop each plant with a good healthy "stool," and in this way heat us as much with asparagus as we heat them with hothouse grapes. Finally, I have to record that their system of small framing is infinitely superior to our own, inasmuch as it is a great deal cheaper. They successfully employ material which would be despised with us, and probably consigned to the rubbish heap. It is true they do not force indoor grapes as we do, and that the best forced grapes at the Exposition were of English growth; but in all small matters, from a good bed of endive or lettuce in the middle of winter to a great melon in early summer, their system is excellent. The salad that one may get in the middle of a hard frost in January in one of the best Parisian restaurants at a couple of francs needs no praise—one is to be had clean, fresh, and perfectly good at a large workman's restaurant near the Boulevard Mont-Parnasse on the same evening for about three sous. This is the result of the capital system pursued by the market-gardeners. They employ a great number of bell-glasses, as large as beehives, and secure a crop of magnificent cos-lettuce in the very dawn of spring. Around Paris you may see acres covered with these great bell-glasses, which cost about a franc apiece, and are useful for many purposes. But it is chiefly in the application of an intermediate degree of heat that they surpass us. They, like ourselves, depend to a great extent on stable manure for affording heat to frames, but apply it very differently and very much more successfully. We use a well-made expensive frame, and place it on the top of a mound of heating material, so that it is only warm on one side. They use a very cheap, rough, and narrow frame, plunge it completely in heating material, cover the top at night with a neat straw mat, and thus preserve a genial and steady temperature at all times. Those little frames are about four feet wide, very cheap, and are excellent for many garden purposes—from the production of early strawberries to the preservation over winter of summer flowers. They are never placed singly, but several rows together, the manure being placed right up to the edge of the frames and forming a narrow pathway between them. The greater portion of the immense collection of hedging plants grown at Passy for the decoration of public gardens and parks is kept all through the winter in these rough and simple frames; but as in this case the exclusion of frost is all that is required, the only material employed to put between them is the rakings of leaves and moss from the adjacent Bois de Boulogne. The French market-gardeners make a great use of these frames at all seasons, while they are also employed in the best private gardens where money is no object. The other day I saw several acres of large melons ripening off in these frames in a large market-garden. The lights had been taken off for some weeks, the full sun being sufficient to perfect the fruit. By looking closely among those melons a leaf or two could be seen pushed aside here and there, and a young cauliflower plant inserted. The sagacious cultivator had, in fact, prepared for a capital crop to come in soon after the melons are ripe. Most likely in a British garden the rich bed of earth in which the melons grow would be left unoccupied till autumn, and then thrown out; whereas the Parisian market-gardener secures another valuable crop before it is time to put in his autumn saladings. I have indeed never seen anything to surpass the careful cropping of these market-gardens. At all times their surface is quite green, and not a spot unoccupied except the little narrow paths that traverse the ground, and the quantity of produce they yield immense. They have always two crops on the ground at the same time—sometimes three. Thus the fine endive which they have now tied up and ready to cut for the market has a crop of lettuce between, ready to spread out and become quickly fit for use as soon as the endive is cut, and so on.

While the poorest Parisian regularly enjoys his palatable salads, nice

button mushrooms are not an unknown luxury to him. The mushroom is grown well and in great abundance under Paris, in the great mines or caves from which the stone for building has been extracted. Their equable temperature is highly conducive to the successful culture of this delicious esculent. As there is, unfortunately, nothing analogous to these caves in the profound bed of putty-like clay which underlies a great part of London, we cannot readily apply the fact to our own wants; but it may be worth relating. Anywhere that an opportunity occurs of making a "mushroom house" in the side of a chalk bank or pit, or in any other position in the earth, it should be taken advantage of; and is there not an opportunity of carrying out the cave system of mushroom growing in some of our mines, especially in those in which horses are employed, in useless railway arches, &c.? In like places, or in any dark cellar, may be produced the *barbe de Capucin*, the cheapest and best salad to be had in Paris, or in any northern clime, in the middle of winter. It is simply common chicory grown in the fields or gardens during summer, and dug up, tied in bundles, and placed in beds of sand in the caves in autumn. There it soon springs up white and crisp, and is sold cheap enough for the poorest to enjoy. There is no reason why Londoners should not also have *barbe*, when so disposed, though it takes time to introduce a thing of this sort to the people. But no English family in possession of a cellar (or even a dark closet, for you may pack the roots in a box) and a field or garden need be without this excellent salad.

Calendar.

WORK FOR WEEK COMMENCING AUGUST 31.

Kitchen Garden and Frame Ground.

CABBAGE to be planted out for spring supply on ground well manured. Collards planted close will now be getting crowded, so draw for use as soon as possible every other one, and ply the hoe between them.

CAULIFLOWER to be pricked out into frames for the winter, and to be kept as hardy as possible.

ENDIVE to be planted out on warm well-manured borders, to stand the winter.

SPINACH must be thinned till the plants are about six inches apart; vacancies to be filled up by transplanting, and if the ground is heavy or trodden during the operation, loosen it with care, so that the roots may have the benefit of the air.

WEEDS will be found to grow rapidly after the favourable showers we have had, and in fact much faster than the autumn crops, and will make their appearance in every place where the seed was allowed to ripen and fall during the summer months. Now is the time to give them an effectual check; and short work may be made of them on a bright sunny day with the Dutch hoe, when they may be either raked up in a neat manner, or left to wither on the ground.

EXHAUSTED CROPS of peas, beans, &c., should be cleared off as soon as they have done bearing, and the ground manured at once, trenched at the first opportunity, and planted with other crops.

LETTUCE to be sown again for the last time. For management of the autumn and winter crop refer back.

MINT to be potted for spring forcing. There is in almost every family a demand for mint before it can be supplied, and the only way to make sure of it is to pot it, then it will be an easy matter to push it on as wanted.

Flower Garden

AURICULAS.—If infested with green-fly, shake a little dry fine sand amongst them, and then blow it out with force, when the insects will be blown out with it. Caterpillars must be sought for diligently, and picked out by hand, or they will soon make general havoc. Keep the soil clean, free from dead leaves and weeds, and stir the surface gently. Shade from bright sunshine, and protect from heavy rain.

BEDDERS to have every necessary attention to keep them in proper order. If seeds are allowed to ripen, the plants will begin to decline in bloom, so remove them promptly, and serve a twofold purpose thereby. Take cuttings of Geraniums in plenty, and to save further trouble put them in pots or boxes as they are to remain for the winter. Use plenty of drainage and a poor sandy compost now, in order to check growth and harden the wood.

CARNATIONS.—Layers to be potted or transplanted, as soon as rooted, in sandy soil; avoid rich soil or stimulating manures, as they must not be encouraged to make much growth, or they will get a gross habit, which will be very detrimental during winter, for then it is necessary that they should rest. Place the pots in a close frame for a few days till fresh roots are made.

GLADIOLI to have regular watering for some time after the bloom is past; but as the foliage begins to decay give less and less, and when the soil in the pots is nearly dry, lay the pots on their sides in the full sun, to promote their ripening. Those in beds will take care of themselves till time to take them up.

LILiums to be treated the same as recommended for Gladioli. Give water till the leaves begin to fade, then lay them on their sides.

PINKS.—Plant out the old stock plants that have been grown in pots into borders, and keep the beds of young ones perfectly clean and free from weeds.

PROPAGATE all sorts of bedding stuff that will be wanted for next year as fast as possible. As soon as cuttings are rooted pot them off, or place in boxes as recommended above; keep them in a close pit or frame for a week or ten days, and then expose them to the weather for a short time before housing them for the winter.

ROSES may be propagated now by inserting cuttings in a bed of light soil in a frame or pit. But a more certain way will be to prepare the cuttings and insert them in damp sand in a shady place, and keep them frequently sprinkled till they callus, and then pot them and plunge them in a gentle bottom-heat.

VIOLETS for bloom during the winter and early spring should be taken up now with good-sized balls, and potted in 48 or 32-sized pots in rotten turf, or a mixture of leaf-mould and road-sand, and then placed in a pit or frame near the glass.

THE GLADIOLUS.—Many of the best varieties of this favourite flower are now in bloom, and selections may be made for next season. The time is

near at hand, too, for purchasing bulbs; and while the subject has a special interest a few cultural remarks may be seasonable. The bloom is generally good this season, and the new sorts have mostly turned out well, and we may therefore consider the flower to have made some real advance in popularity. It may be safely said that for decorative purposes there are no had gladioli, though among the named varieties some are better than others, and those who have what is termed "a florist's eye" will prefer flowers with broad segments, flat faces, and smooth edges, provided they have firm, pure, and regular colour. One of the principal causes of disease in gladioli is *keeping them too long out of the ground*. The practice has been to pot them or plant them in April or May. The consequence is, they have not time to make roots before the heat of the weather pushes up the flower-spikes, and the sap is consumed faster than the roots can furnish supplies. In such a case disease *must ensue*. Another mistake is the fear of using manure. Some very foolish papers on gladioli appeared a few years ago in the gardening journals, and did much mischief. People were told that manure was poison to these plants, and the consequence was that, being in the first instance impoverished by planting too late, they were next badly fed through fear of using manure. With two impoverishing causes against them, no wonder many an amateur lost his stock, and was disgusted for a season. *Early* planting is essential to success. If the bulbs are ripe and *hard*, they may be potted in September, but as there need be no great haste, hyacinths and crocuses may be disposed of first. Instead of waiting till April and May, take care that every gladiolus bulb is in the ground before the 1st of February, and if any quantity is required, pot them in successive batches, so as to secure a long season of bloom. Imported bulbs are, of course, ripe earlier than those grown at home, and may be potted before it would be safe to take up our own. And, indeed, as to taking up, if the beds are rather dry and safe from frost all winter, the next season's growth and bloom will be finer than by the system of annual planting. There are two evils to guard against in winter; do not let them be touched by frost, and do not force them into growth. Suppose a bed of gladioli now in full bloom; they will probably keep green till the end of October. If they are green then take them up with as little injury as possible, put them into pots without injuring the roots, fill in with any fine soil,—mere grit or cocoa-nut fibre will do,—and place them in a sunny pit or greenhouse. After potting, water them once, and after that do not give them a drop. This treatment will cause them to ripen off, and, to complete the process, expose them to the full sunshine on a shelf of a lean-to house, or in any dry place where there is some degree of warmth, to ripen them; remembering that in their native country the bulbs get well roasted by sunshine before the winter sets in, and that the winter they are subjected to is a very mild affair. The best material for covering the beds is new straw. Lay this on at the end of November, six inches thick, and over it throw two or three inches of quite rotten dung, which hides the straw, and adds to its protective powers. Take off the straw in March, and then rake the powdery manure evenly over the bed, and the growth subsequently will be satisfactory. As to soil, a good turfy loam with plenty of sand, leaf-mould, and thoroughly decayed manure is the best they can have. Good drainage is indispensable; and in case of a long continuance of hot dry weather, in a place where the soil is thin over chalk or gravel, liberal watering should be done. However, as a rule, these, like other subjects *properly* planted out, do better without artificial watering than with it. When grown in pots, let the compost be mellow turfy loam two parts, and one part each of leaf-mould, sharp sand, and thoroughly decayed manure, say, for example, three-year-old hotbed dung. They may be potted singly in five-inch pots, but are more effective if three or four bulbs are put into a seven-inch pot; and for peculiar purposes such sorts as *Brenheleyensis* or *Bowiensis* may be potted in ten or twelve inch pots, using seven or eight (or more) bulbs in a pot. These, when in bloom, would make magnificent ornaments for a terrace-walk or the front of any building. Another mode of dealing with them is to combine pot culture and planting out, and this should be done by all who are afraid to leave their bulbs out all the winter. Pot them singly in January, and plunge the pots to the rim and cover them a few inches deep with some protective material. During frost lay branches of spruce over, or in any other way that may be convenient, protect them from frost. By the 1st of May the pots will be full of roots, and they may then be planted where they are to bloom, and this, of course, should be done without any damage to the roots. There is yet another way of forwarding them preparatory to planting out, and that is to bed them in frames without pots. Cut a lot of grass turfs into breadths of about six inches, set them on edge, six inches apart, and fill in between with suitable soil. Then plant the bulbs in these divisions six inches apart, and leave them till the first week in May, when, the beds being ready to receive them, they may be lifted out of the frame in squares, and be planted where they are to remain.

SPRING FLOWERS.—Now is the time to make notes for next year's decorations, and it is a good time to buy in hardy herbaceous plants for flowering in the spring. Messrs. Dillistone, of Sible Hedingham, Essex; Mr. Webb, of Calcot Gardens, Reading; and Messrs. E. G. Henderson, of St. John's Wood, London, are rich in choice spring-flowering plants. Daisies, polyanthuses, primroses, and violets may be parted and planted now.

GARDEN PLANTS IN BLOOM.—*Pentstemon breviflorum*, *diffusum*, *Aster luxurians*, *multiflorus*, *inuloides*, *artimisiiflorus*, *Solidago procera*, *gigantea*, *Lysimachia ephemerum*, *Aconitum chinense*, *Anemone vitifolia*, *Japonica*, *Linaria vulgaris peloria*, *purpurea*, *Helianthus linearis*, *giganteus*, *trilobatus*, *Veronica complicata*, *Rudbeckia fulgida*, *asperima*, *columnnea*, *Vernonia angustifolia*, *oligophylla*, *serratuloides*, *Pyrethrum uliginosum*, *Hemerocallis Sieboldii*.

Fruit Garden and Orchard House.

CROPS of apples and pears to be gathered now as they ripen, always selecting a dry sunny day for the purpose, if possible; be careful to preserve them from bruises.

PEACHES and **NECTARINES** must be looked to as soon as the last fruit is gathered; if any are infested with red-spider, dust them liberally with powdered sulphur early in the morning before the dew is off the leaves, or else syringe them well before the operation, so that the powder may adhere.

Greenhouse and Conservatory.

GREENHOUSE and **CONSERVATORY** must be cleaned thoroughly at once, and got ready to receive the plants which are standing out of doors, for as boisterous winds, heavy rains, and sudden changes are to be expected soon, it would be well to stage the choicest and tenderest of them at once. When arranging them, have an eye to a general pleasing effect; put them so far apart that the air can circulate freely all around them;

and don't shut them up close. Examine the surface of the soil, and if any signs of worms are visible, turn the ball carefully out of the pot, when they may generally be picked out; supposing, however, that they are still invisible, do not break the ball to look for them, but return it to the pot, and stick a peg in it to serve as a reminder till the intruder is captured. Remove dead leaves, &c., from the plants, and see that the drainage is faultless. Give all the air possible, and only reduce the ventilation when there is an unfavourable change in the weather.

HELIOTROPES to be kept in healthy growth for winter flowering.

Sow mignonette for winter blooming."

GREENHOUSE PLANTS IN BLOOM.—*Borbonica cordata*, *Arctotis decumbens*, *Gesnera discolor*, *Douglasii*, *zebrina*, *elongata*; *Bignonia jasminoides*, *Venusta*, *Angophora cordifolia*, *Banksia verticillata*, *Nivenia spicata*, *Coeha scandens*, *macrostema*, *stipularis*, *Grindelia coronopifolia*, *Lambertii*, *Vinca pusilla*, *Meyenia erecta*, *Opuntia Dillenii*. Many of the Chinese primulas are now showing a fine bloom, and some of the species of *Cytisus* and *Coronilla* are now in flower. *Ericas*: *Oblonga*, *obtusa*, *pellata*, *infundibuliformis*, *amabilis floribunda*, *Farriciana*, *versicolor major*, *verticillata major*, *Archeriana*, *carneola*, *exposita*, *flava imbricata*, *curvifolia rubra*, *exsurgens major*, *Cushiniana*, *Eweriana longifolia*, *mammosa*, *vestita mutabilis*, *Savileana*, *radiata*, *pellucida rubra*.

MIGNONETTE IN POTS FOR ALL SEASONS.—Amongst all the odoriferous plants which are cultivated for decorating the conservatory and the drawing-room, there is none more universally admired or more easily cultivated than the mignonette; and yet it is seldom that we see it brought to that perfection of which it is capable, more especially during the winter and spring months. *Reseda odorata*, or the Mignonette, is a native of Egypt; it is, under ordinary treatment, an annual plant, growing from six inches to a foot in height, and is hardy enough to stand this climate during the summer months; but it will not survive our ordinary winters, unless in some very sheltered situations. In order, therefore, to obtain a regular succession, recourse must be had to pot or box culture, which will form the subject of the following remarks: The beginning of February is early enough to make the first sowing for a spring supply. The soil which should be used should consist of one-half loam, one-fourth part dung, and one-fourth part leaf-mould, well mixed together, and used in as rough a state as possible: the worms (if any should be in the soil) ought to be carefully picked out, or they will cause great injury to the plants, by stopping the drainage and disturbing the roots. The pots known as "forty-eights" will be large enough for this sowing; and these should be prepared by placing a crock over the hole in the bottom, and laying on this about two inches of the roughest of the soil, after which they should be filled with soil, pressed evenly and firmly, leaving the surface level within half an inch of the rim. On this the seed should be sown regularly, and, if its quality can be depended on, two dozen seeds will be enough for each pot; they will come up stronger than if sown thicker. Sift a little soil over the seeds, and give this a gentle pressure with the back of the hand, leaving the surface smooth and even, but not "glazed;" then give a gentle watering with tepid water, which will warm the soil and assist germination. Plunge the pots in a frame with a gentle bottom-heat, and keep the lights shut till the plants begin to appear; afterwards admit a little air every day, if the state of the atmosphere will allow; but at all times avoid the admission of currents of cold air, as I am convinced that mignonette suffers severely from too rash an exposure to cold winds. When the plants become a little innred to exposure, remove the lights every fine day, which will prevent them from being drawn, and better enable them subsequently to support themselves. As soon as the seed-leaves are fully developed, thin out the plants, leaving at this time ten or twelve in each pot; this number should be retained, as they are liable to damp off if over-watered, and especially if the weather should happen to be dull. When they have made three or four leaves, thin them out to five plants, which number is sufficient for a 48-sized pot; at the same time stir the surface of the soil, which often becomes caked by continual watering, and thereby prevents the access of air to the roots. When the sun begins to act powerfully upon them, a thin shading for a few hours during the heat of the day will be of great service, by obstructing its rays, which give to the foliage a yellow and unsightly appearance. When they have grown three or four inches, they will require to be tied up, to prevent them from falling over the sides of the pot. In doing this place five small stakes at equal distances close by the edge of the pot; then pass a strip of matting, with a turn round each of the stakes, and fasten it: it is necessary to leave the stakes two or three inches higher than the plants, as I have found them sometimes to require a second tie. If the roots at that time have found their way through the bottom of the pot, they must be broken off, or the plants will receive a severe check when finally removed. In re-plunging them, give them sufficient room to prevent their being drawn. They will require little more attention, besides giving plenty of air, watering, and shading, till the middle of May, when they will be in good condition for removing to the conservatory. The next sowing will require to be made about the beginning of April. The same compost as previously recommended should be used. For this sowing, however, I would prefer 32-sized pots, and would allow seven plants to remain in each: by thus having a greater body of soil, it will be found to retain moisture for a greater length of time, and the plants will not be so liable to receive any check by an accidental omission of watering. In other respects the treatment already detailed should be followed. By the middle of May, if the frames should be wanted for other purposes, the pots may be plunged in a shady place out of doors. They will come into bloom about the beginning of July. Other successional sowings should be made about the beginning of June and the beginning of August. These may be plunged in a sheltered spot out of doors; and, with attention to watering, thinning, and tying up, as previously directed, they will come into bloom respectively about the middle of August and the end of October. The latter of these sowings must be removed to a frame as soon as danger from frosts may be apprehended. The next sowing, which is to provide plants for blooming through the winter months, must be made about the middle of September. A little more attention is necessary at this season of the year, in order to prevent them from damping off, and also to secure as much of the sun's rays as possible. The soil I would recommend for this sowing consists of three parts of loam, one part of dung, and one part of leaf-mould. My reason for using more loam at this season is, because the compost then retains moisture longer than if a less proportion were employed; and thus the necessity of frequent applications of water is in great measure done away. In dull weather mignonette is very impatient of water; and, when it is applied, it should be done in the morning, in order that the foliage may become dry before night. For this sowing I would use 48-sized pots, giving them a good drainage. In

preparing the frame for their reception, it should be raised behind, so as to give it a good inclination towards the south, for the purpose of gaining the full benefit of the sun, and also of preventing drips, which are very injurious, as the plants seldom recover from checks occasioned by their becoming very wet. The bottom of the frame should be covered with brick rubbish, and over this there should be a stratum of rough coal-ashes, and again, on the top, six inches of finely-sifted ashes. This must be arranged so that, when the pots are plunged, they may not be more than nine inches from the glass. When the seeds are vegetated, give as much air as possible; and by attention the plants will begin to flower about the beginning of December, and keep in good condition for three months. The final sowing should be made about the beginning of October; using the same sort of soil and pots, preparing the frame in the same manner as directed for the preceding, and taking great care in the watering and thinning. By the beginning of March the plants will commence flowering. When frost sets in, cover the glass with mats and loose hay, taking them off on every favourable opportunity, as the young plants, when excluded too long a time from the light, will turn yellow and damp off. I would also lay some long litter around the frame, to prevent the frost from penetrating through the sides.

Stove and Orchid House.

ORCHID HOUSE to be shaded as little as possible, so that the pseudo-bulbs and strong healthy shoots may be assisted in ripening off by the influence of the sun; the process to be perfected by keeping up a genial atmosphere, ranging from 70° to 80°, with abundance of air in favourable weather. Give plenty of water to such as are growing freely, but very sparingly to those which are now rapidly approaching their season of rest. *Cattleyas*, *Lællas*, *Odontoglossum grande*, and *Lycaste Skinneri* may be kept rather cool with an occasional slight syringing. Orchids that have quite finished their growth for the season will require plenty of air during warm weather, to assist in ripening their pseudo-bulbs, and at the same time less water must be given. But in such a season as this the adventurous cultivator will sometimes encourage further growth by using a high temperature and plenty of moisture, reckoning upon having time yet to put the plants to rest safely. Many of the *Vandas*, *Saccolabiums*, and *Dendrobiums* will submit to this sort of treatment very cheerfully, and where there are abundant evidences of an inclination to keep growing, it is not at all advisable to check it. Young plants generally are reluctant to cease their growing, and these must have plenty of moisture and continued shading. But those that are unmistakably settling down to rest should no longer be shaded, and there must be a decrease of temperature and of water supply. Established plants of *Cattleya*, *Lycaste*, *Odontoglossum*, and *Lælia* will, for the most part, require no more stimulus this season, but they must nevertheless have light but regular refreshings from the syringe. *Stanhopeas* must be looked to, that they do not go too dry, which is very likely to happen if they have not been put into new baskets this season.

Forcing Pit.

VINES.—Pinch off laterals, as it is too late for the plants to benefit by leaves formed now, and remove useless growths.

FINERY.—Pines growing freely must have the aid of weak manure-water, and a moist atmosphere, but the bottom heat must be brisk if any stimulants are used. Shading may be removed early this month. Guard against forcing small plants into fruit, and to prevent it keep the plants growing by frequently sprinkling the beds and paths of the house. Bottom-heat for pines 84°, those ripening to be kept tolerably dry. Young stock to have air cautiously, which is best done when in dung-beds by first applying a lining to keep up the heat, which will allow of giving a little air at night.

FEMALE LOVE OF FINERY.—The Countess of Waldegrave was present last week at a school examination at Wigton, and delivered a short address, in the course of which she said: "I wish to speak to the females present, especially mothers. There is a subject which I believe a great many will join with me in thinking important in these times in which we live, and that is the subject of female dress in all ranks of life, but especially among those who attend our schools. I regret to say that there is a great deal of what may be called useless finery among the young girls of the present day, and I should think that probably mothers are a little to blame in that particular. I have observed this passion to be on the increase during all my life; and as God's mercy has spared me through eighty years, I think I may speak from experience on the subject. I must say I think it a great mistake on the part of mothers to dress their children to the utmost extent of their means, instead of inducing them to lay by their pence for what is called a rainy day, or to collect clothing for winter; in place of which they allow their girls to spend all their little money, and what they can add of their own as well, on what I should call unnecessary and useless finery. I am very glad to find that you educate the children well here, and I am delighted to see that needlework is made a very particular point of examination in many of the schools; because, in seeking for female servants, we all want those who can be useful in those particulars, as well as in knitting and darning, for which I have had pleasure in giving prizes in my own country on various occasions. Now, while children are taught to spend all the money that they can get together on little bits of finery, the first thing a mistress has to teach her young servant is to dress neatly, and properly, and respectably, and thus correct the great mistake of mothers who help their children forward in unnecessary outside clothing, while very often, I regret to say, the inside is exceedingly deficient (laughter and applause). I therefore hope that mothers who have such opportunities of having their daughters educated—and you have many compared to those enjoyed in my part of the country—will earnestly strive to give them that degree of propriety and neatness in their dress which is always respectable, useful, and efficient. I trust you will excuse me, coming such a distance as I do, for making mention of what many, if they would speak out, really feel in their hearts (applause). I am often told by mothers, 'Well, ma'am, I can't help it. My girl will go to the second-hand shop and get these bits of things, where they are cheap. And it is only a penny flower, and a flower does not wear out so soon as a ribbon' (laughter). Well, but that is not neat, nor is it desirable; and when they get into service, most mistresses will object to that kind of finery which is not suitable to the station in which it has pleased God to place them (hear, hear). I hope my female friends will excuse me for giving them these hints, for they are the result of long experience."

The Gardener's Magazine.

SATURDAY, SEPTEMBER 7, 1867.

THE EFFECTS OF A HOT MOIST AUTUMN, following a cold and rather dry summer, are likely to be, upon the whole, beneficial. To speak of matters of somewhat trifling import first, we may direct attention to the comparatively sudden and very decided improvement of many kinds of bedding plants, more especially those that produce effects by the colours of their leaves. These have been, for the most part, very unattractive; in fact, somewhat unsightly until quite lately, but, with the augmentation of solar heat accompanied with a due degree of moisture, the species of Coleus, Iresene, Perilla, Amaranthus, and other like subjects, have suddenly acquired their proper splendour, and the season of the parterre promises to close as gloriously as the close of a bright day, when the western clouds are richly painted, or as one of the greatest modern poets described the dying of the dolphin. So far good; if we are to have bedding, and in great gardens it is as indispensable as it is superfluous in little ones, let us have it in the most gorgeous style possible, let not taste be violated, but let us have every plant in its true colour, and if the elements hinder the development of colour it is a matter for general regret. Another of the advantages of the increased temperature is, that we may look for a perfect ripening of all the growths of the season. The young shoots of trees will be hardened, fruits and roots will finish their career honourably, seeds are likely to be good; we may cease to tremble for the harvest. The moisture and the heat together favour greatly all autumn sowings of seeds: turnips are doing extra well, there is a prospect of abundant winter feed on the farm, and of winter vegetables in the garden; whatever growing remains to be done will be well done we have no doubt, and we shall have special cause for thankfulness that a summer so unpromising should close its career with so much of promise.

But let us learn caution from past experiences. The rains now falling are accompanied with high temperature. The wind is westerly, and likely to continue so for some time to come. The farmer and the gardener have alike to guard, so far as they can, against the second growth of subjects which should now cease growing and go to rest. Unless an early frost prevents it, we shall soon see a beautiful second growth in all forest trees; amidst their brown leaves will be tender green shoots, and that pretty dappling of colour peculiar to seasons such as the present. In the fruit-garden something similar may be expected, and we need not tell the practical reader that late growths on fruit-trees are absolutely worthless. To prevent this partial lifting is perhaps the best possible proceeding. Old fruitful trees rarely break into second growths; therefore, as it is impossible to lift them, so also is it unnecessary. But miniature trees, bushes and pyramids, are all likely, being in an artificial condition of restraint, to break away into sappy shoots to their own injury; and the only check to this absurd proceeding is to gently and carefully heave them over, or, in other words, to commence operations for lifting them, and to cease working when they are just ready for the last lift. The check to root-action will promote perfect ripening of the useful wood, and quite check the development of wood that could be of no use ultimately, and which is extremely likely to be destroyed in the winter.

There is great danger of a second growth commencing with potatoes yet remaining in the ground. Where they are yet green and growing, this is not to be apprehended, but where they are ripe, or nearly so, every day that they remain in the ground adds to the probability of their deterioration. Wherever potatoes are ripe, or nearly so, even if the haulm is still a little green, it is advisable to lift them at once. Let them be housed while they are good—and, generally speaking, they are good; and those who make much moan about disease deserve to have cause to moan for their morbid sensibility. The potato harvest of 1867 promises to be one of the best ever gathered; and we may attribute its general perfection to the augmentation of solar heat during the ripening of the tubers. While the temperature continues high there need be no fear of disease; but, we repeat, a second growth is extremely likely to take place. As tubers cannot form tubers

when unaided by leaves, without deterioration, so, though a second growth may increase the total number, it can only decrease the total value, and is to be prevented if possible. Many other precautions will suggest themselves to practical men as the result of these remarks. Let us obtain, if we can, by the exercise of caution, prudence, and vigilance, a maximum of advantages with a minimum of disadvantages from the peculiar conditions of atmosphere at present prevailing.

THE CENTRAL PARK, NEW YORK.—In the *Times* correspondent's letter from New York, published on Monday last, occur some interesting particulars of this grand undertaking. He says, "You have heard so much of mismanagement and corruption in the city of New York, that it must be almost a relief to be told of a great work which has been carried out with perfect success for the free benefit of the public, and without the waste or misuse of a single dollar. I refer to the Central Park, destined in a few years to be the most beautiful park in the world, and already far superior to anything of the kind in America. Those who have only driven round have but a very poor idea of its extent; to see it properly, one should explore it on foot. It is full of exquisite walks by lakes, or through miniature woods and plantations, and hours or days even may be spent there (as I can testify from experience) without exhausting their beauties. The trees are young yet, but some idea of the efforts which are being made to get the park well wooded may be gathered from the fact that last year nearly 18,000 trees and shrubs were planted. The park drive is within a fraction of nine and a half miles in length, there is a bridle road of five miles and a half, and a length of walk available to the public of over twenty-six miles. The cost of this park to the city, including the purchase of land, has been little over 10,000,000 dollars. In the winter there is an unrivalled skating pond open to the visitors, and in summer bands of music play popular selections on one or two days a week. In every respect the park is managed for the convenience and benefit of the public, and every cent produced by the tax for its maintenance is honestly devoted to the improvement of the ground. If any one is puzzled to account for the fact that while this park is so great a credit to the city, everything else in it connected with the corporation is a disgrace, he must be informed that the citizens were wise enough to keep the park entirely beyond the control of the city authorities. Their rapacious and dishonest fingers—always let it be remembered that the mayor of the city is a gentleman of unblemished integrity—have never been permitted to handle the money designed for the common benefit of all. If they had, we can easily imagine what the park would have been like. It would have been scarcely so ornamental as Boston Common, while it would have been made the pretext for practising every kind of extortion and roguery upon the people. But the whole design was entrusted from the first to the guardianship of gentlemen of high character and position in the city, and they have ever since done their work, and very hard and onerous work it has been sometimes, without the least charge to the public. The Board of Commissioners, with Colonel H. G. Stebbins, the commodore of the New York Yacht Club, and one of the most deservedly popular men in America, have deserved the gratitude of the public for setting an example to the city corporation."

SOLDIERS' GARDENS.—The "garden allotments" of the soldiers of Portsmouth on an extensive piece of ground outside the head-quarters boundaries, and lent for the purpose by the War Department, are well worth a visit from any one who may be in the neighbourhood, and who feels an interest in the barrack-life of the soldier. Each plot of a company has its fringe of flower-beds which now are glowing with colour, and many of them contain flowers of more than common worth. The remainder of the plots are covered with fine vegetable produce, in seeming sufficiency to supply a large army. In some parts of the country the troops have been permitted to work in the harvest fields. Surely it would improve the morale without deteriorating the physique of the army to encourage in every reasonable way the practice of gardening as the favourite recreation for soldiers. In too many instances beer destroys money, time, health, and decency, and "Satan finds some mischief still for idle hands to do." Soldiers everywhere, except when in the field, should have gardens. The gain in respect of order, health, and loyalty, would be immediate and immense, and in the event of a long campaign in an enemy's country, the knowledge acquired in barracks might be of great service in aid of the commissariat as well as to give a cheerful side to painful duties.

THE PEACH CROP in the Southern States of North America has been a large one, and yet has realized good prices. In Kentucky the crop has averaged from two to three dollars per tree, large purchases having been made for preserving.

A NEW WOUNDWORT.—The loaves of geraniums are said to be excellent for cuts where the skin is rubbed off, and other wounds of the like kind. One or two leaves must be bruised and applied to the part, and the wound will be cicatrized in a short time.

FLORA IN THE NEW WORLD.—New York spends 400,000 dollars, and Boston 200,000 dollars, annually, for cut flowers. All know that large sums are paid for presentation bouquets and baskets; but some people would be astonished to see what money is expended regularly for flowers, by families who think they are economical. A New York merchant of ordinary means thinks nothing of spending fifty dollars for artificial flowers to decorate his table when he has a few friends to dine.

VEGETABLE DYES APPLIED TO STONE.—Variegated marble is now imitated in all the rich-coloured veins for which some species of it are distinguished. For this purpose a solid block of marble, to be treated, is first warmed in an oven to open its pores, after which the colours are applied. These consist of an alcoholic solution of alkanet root, to produce a rich lavender, a madder lake to make a crimson, indigo to produce a blue, verdigris green, and gamboge yellow. They are put on according to the fancy and taste of the artist, so as to form the desired patterns, after which the marble is again warmed to make it absorb the colours.

MANCHESTER BOTANICAL AND HORTICULTURAL SOCIETY.

The last exhibition of the season took place at Old Trafford, in connexion with the centenary gathering of the Liverpool and Manchester Agricultural Society, and was continued from the 27th to the 31st of August, five days inclusive. It was a highly meritorious affair, rich in all the several subjects proper to the season, and especially so in cut flowers and valuable decorative plants. Two great tents, on the site of the National Exhibition of June last, were appropriated for the purpose; and consequently for some part of the display—that comprising specimen plants, for example—the advantages of green banks and picturesque effects were obtained. In the first tent a central table, well filled with spikes of hollyhocks, gladioli, grand bunches of grapes, and miscellanies, divided the space into two broad walks, beyond each of which, forming the boundaries of the tent on either hand, were banks of cut flowers, fruits, ferns, and other subjects of comparatively small size. The second tent was grandly filled with bold artistic groups of tree-ferns, palms, ericas, and miscellaneous gatherings from the stoves and greenhouses of the district, comprising such subjects as Crotons, Caladiums, Rhopalas, and the like; and these were lighted up by an abundance of zonal and variegated geraniums, cut flowers, and other light subjects. Nor was it any detraction to the finish and beauty of the exhibition that there was a profusion of vegetables and fruits contributed by gardeners and cottagers; and, in respect of the last-named class, we must do them the justice to say that, although what they sent was of necessity interesting, they for the most part presented such admirable examples of horticultural skill that the exhibition would have been storn of one of its best features had they not been there.

ORCHIDS.—There was a class for ten exotic orchids, poorly filled, yet perhaps, considering the time of year, the plants were no discredit to this generally good show. The first place was awarded to J. A. Turner, Esq., of Pendlebury (gardener, G. Toll), for a pretty group, comprising *Odontoglossum grande*, *Aerides nobile*, *Onoidium incurvum*, *Lælia gigantea*, *Vanda suavis*, *Disa grandiflora*, with three spikes of flowers, a pretty example of a plant which does not show well in a group; *Aerides suavis delicatissima*, *Odontoglossum hastilabium*, *Saccolabium Blumei gigantea*, and *Cattleya labiata pallida*. Dr. Ainsworth (gardener, G. E. Mitchell) second, with *Lycaete Skinneri*, *Lælia gigantea*, *Miltonia virginalis*, *Miltonia Regnelli purpurea*, *Miltonia spectabilis*, *Vanda Lowii*, *Lælia Turneri*, *Cattleya Schilleriana Regnelli*, *Onoidium incurvum*, *Odontoglossum hastilabium*. Some of these plants looked as if they had been exhibited on previous occasions this season, and had not yet quite recovered. The plant of *Vanda Lowii* was one of the best of this fine species we have yet seen: it had three fine racemes, the basal flowers bright orange and buff, the others crimson-brown and white lip, the two distinct classes of colour being a constant character of the species. The third place was awarded to Mr. Stafford, of Hyde, who had clean and bright examples of *Dendrobium chrysotoxum*, *Epidendrum vitellinum*, *Odontoglossum grande*—the last a finer variety than the one generally grown, having broader segments and richer colours. Dr. Ainsworth also contributed an extra group, comprising *Promeneia stapeloides*, on a block, with two fully-developed flowers, quite a gem for lovers of curiosities, and, though a strange dull thing, not destitute of a certain kind of beauty; and a poor plant of *Cologyne speciosa*, with two of its eminently unattractive flowers. There were also examples of *Vanda suavis* and *Renanthera matutina* shown apart from the classes the first of these two was an extra fine specimen; the second was a middling good plant, of a scarce and not much valued species; it is certainly far inferior as a decorative subject to the better known and everywhere admired *Renanthera coccinea*. It may not be out of place to notice here a contribution of a very interesting kind, though it takes us aside from the orchids. This was a raceme of flowers of one of the species of *Nepenthes*. The name was not given, but it appeared to be *N. phyllamphora*. The stem was about twenty inches in length, beset throughout with small flowers of a dull brown colour, about 100 in number, and apparently consisting in great part of females, as in very few could we perceive the peculiar club-like stamens by which the males are distinguished.

STOVE AND GREENHOUSE PLANTS IN FLOWER.—As remarked above, these were abundant and beautiful, and it is perhaps especially desirable the names of the subjects shown should be fully reported, as there are but few exhibitions at this time of the year at which first-class subjects of this kind are to be seen, and cultivators are interested to know as much as possible respecting plants presentable now. The first place in the class for eight plants was taken by Mr. John Stevenson, of Timperley. Here were five examples of *Erica emula*, *obbata*, and *Faireanum*, *Cattleya devoniensis*, *Phenocoma prolifera Barnesii*, *Allamanda Schottii*, and *Hendersonii*, *Bougainvillea glabra*. In the class for ten miscellaneous, the first place was taken by Thomas Hobson, Esq. (gardener, W. Cardwell), with splendid examples of *Anthurium magnificum*, *Cyathea dealbata*, *Dasylium acrotrichum*, *Croton longifolium*, *Yucca aloifolia variegata*, *Allamanda Hendersonii*, *Geonoma magnifica*, *Theophrasta imperialis*, *Cordylina indivisa*, *Erica tricolor Wilsoni*. Second, Mr. John Shaw, of Manchester, with *Croton variegata*, a grand plant of the beautiful *Eurya latifolia variegata*, five feet high, a perfect pyramid; *Rhopala corcovadense*, *Yucca aloifolia variegata*, *Phoenix sylvestris*, *Pandanus ornatus*, and some beautiful tree-ferns. Third, Mr. Stafford, of Hyde, with a pretty clump of *Vallota purpurea*, *Lilium lancifolium album*, *Aralia Sieboldii variegata*, *Latania Bourbonica*, *Pandanus utilis*, &c. In the class for six miscellaneous, first, Thomas Hobson, Esq., with *Gleichenia flabellata*, *Cordylina Australis*, *Croton variegata*, *Erica ampullacea major*, &c. Second, S. Schloss, Esq., with a most charming plant of *Davallia tenuifolia*, one of the very best of this tribe, possibly surpassing in beauty *D. aculeata*, and in airiness of style reminding one of *Ouyohia japonica*; *Bougainvillea glabra*, &c. Extra, Mr. Shaw, with some good palms, cycads, yuccas, &c. The best single stove plant in flower was a fine *Bougainvillea*.

ERICAS.—There were but few of these, but the quality of all was of the highest: the plants large, round, bushy, bright with flowers, and without any exception fresh and honest. Mrs. Cole and Sons, of Wittington, first in the class for six, with *Irbyana*, *Insignis*, *Jacksonii*, *Metulæflora*, *Emula*, *Austinianum*. In the class for the best single heat, T. Hobson, Esq., with *Irbyana*; second, Mrs. Cole and Son, with *Irbyana*.

ACHIMENES were good. First, J. C. McConnell, Esq. (gardener, John Smith), with fine round dwarf plants of *Edmund Bossier*, *Carl Wolfurth*, *Longiflora major*, two of each. Second, Thomas Hobson, Esq., with *Leopard*, *Scarlet Perfection*, this is a fine scarlet kind, free to flower, and an advance upon *Dazzle*; *Purpurea elegans*, *Edmund Bossier*, *Carl Wolfurth superb*; *Colonel Watford*. Third, Mr. Rylance, with *Colonel Watford*, *Amroise Verschaffelt*, *Rose Imperial*, *Dr. Hopf*, *Longiflora major*, *Dazzle*.

GLOXINIAS were good; plenty of flowers, no rags; the varieties good. First, Mr. Rylance, with *Madame Picouline*, *Grandis*, *Conspicuous*, *Madame Warner*, *Showgood Seedling*, lavender purple; and *Seedling*, fine puce purple. Second, E. Brooke, Esq. (gardener, E. Milford), with *Helen of Orleans*, *Brilliant*, *Sir Hugo*, *Perfection*, *Keleckeri*, *Princess Alice*.

LILIUM.—The best four *Lilium* came from — Brocklehurst, Esq. (gardener, J. Miller), all of them varieties of *lancifolium*, fine plants, rather drawn through being flowered under glass, which is no benefit to them. Too much same-ness in the group. Best three pots of *Auratum*, first, Mossrs. Yates, of Manchester, with short handsome plants, profusely flowered, and fresh in leaves to the bottom. Best single specimen of *Auratum*, E. Philippi, Esq., with a giant about seven feet high, the expanded flowers thirteen in number, and nine more coming. This was not drawn, but had naturally made a single towering spike.

FINE FOLIAGED PLANTS, INCLUDING PALMS AND FERNS.—The first prize in the class for 10 fine-foliaged plants was awarded to Mr. Stevenson for a group of extraordinary specimens, gigantic in dimensions, admirably grown, fresh as the face of the pimpernel on a sunny forenoon, and comprising subjects of great value and the highest decorative excellence. We did not obtain the name of the winner of second prize in this class, owing to the absence of the card at the time our notes were made. Whoever it was, need not be ashamed to be placed second to Mr. Stevenson, for scarcely anywhere in England could his plants be surpassed. The second lot was, moreover, a very few degrees less meritorious; and as to condition and culture, there was nothing wanting. The two lots were grouped on one bank, and made a most imposing picture. They comprised examples of

Alocasia Lowii, *A. metallica*, *A. zóbrina*, *A. macrorhiza* var., *Caladium Belleymei*, *Croton variegat.*, *C. angustifolium*, one of the finest ever shown; *Theophrasta imperialis*, *Yucca aloifolia variegata*, *Spherozyne latifolia*, a big plant, every leaf perfect; *Anana sativa variegata*, *Latania Bourbonica*, *Gleichenia flabellata*, *Anthurium grande*, *Cordylina Australis*. Tree-ferns were abundant: the best six came from Mr. Stafford, of Hyde; they were *Dicksonia squarrosa*, *D. antarctica*, *Cibotium princeps*, *Alsophila Australis*, *Cyathea medullaris*. The best 12 hardy ferns came from Mr. Rowbotham; a fine *Trichomanes radicans*, *Blechnum spicant anomalum*, *Polystichum acrocladum*, *P. angulare proliferum*, *P. a. plicatum*, *Scolopendrium vulgare undivifolium*, *S. v. submarginatum*, *S. v. cristatum*, *Athyrium Filix femina densum*, *A. f. f. Fieldii*, *A. f. f. plumosum*, *A. f. f. Todioides*. All the *Athyriums* were labelled *Asplenium*, for which we have the authority of Deskin, Hooker, and Arnott; but the accepted generic name for the Lady fern now is *Athyrium*, and they ought to be so labelled at exhibitions. Second, Mr. Shaw, with a quite second-rate lot; but amongst them were good plants of *Scolopendrium vulgare glomeratum*, and *S. v. digitatum*, and *Adiantum pedatum*; and, better than all, a large piece of *Trichomanes radicans*, shown (as in June last) without a bell-glass. Mr. Shaw shall have our best thanks if he will tell us how he manages to present this at a five day's show thus unprotected. Is there any magic in it? The plant appeared by its intensely dark green colour never to have known the comfort of a bell-glass, and it just reminded us of the peculiar dark green leaves of Messrs Veitch's specimens of *Spirea japonica* shown at the Manchester National, and which we did not fail to award warm praise in our report. Third, Mr. Rylance, who had a good *Lastrea Filix mas cristata*, and some beautiful varieties of *Scolopendrium*, which are always good exhibition subjects. Palms were conspicuous both in mixed and special classes by their freshness and beauty, and in variety they were not stinted. The first place in the class for 4 was awarded to H. Blackmore, Esq., of Pendleton, for splendid specimens of *Latania Bourbonica*, *Verschaffellia splendida*, *Calamus dealbata*, and the best *Phenacophorium sechellarium* in the show, the leaves being richly stained with the clear cinnamon hue peculiar to this species, and all the leaves (about ten in number) perfect. By the way, this is no longer to be called the "thief palm," Old Bailey and assize associations are abolished; it is henceforth to be labelled *Stevensonia sechellarum*—please make a note thereof, Mr. Blackmore. Second, Mr. Hobson, with *Latania Jenkinsonii*, *L. Verschaffellii*, *L. Bourbonica*, and *Coroxylon niveum*. Mr. Shaw had *Scaforthia elegans*, *Areca rubra*, *Geonoma Gheshrechtii*, and *Phenacophorium (Stevensonia) sechellarum*.

Mr. B. S. Williams, of Holloway, London, occupied a great bank with a collection of plants not intended for competition. Here were many plants of great value, and, as fine foliage and flowers were freely mingled, the effect, in a decorative point of view, was fully equal to the interest attaching to the plants themselves. Amongst the larger subjects were examples of *Phenacophorium sechellarium*, *Agave schidigera*, *Yucca filifera*, a very fine habited plant of the most compact construction, very dwarf; *Nepenthes phyllamphora*, *Maranta Lindenii*, *Nepenthes hybrida maculata*, *Maranta Veitchii*, *Beaucarnea longifolia*, one of the grandest of this grand family, the leaves five feet long, and beautiful in colour and brightness. The more noticeable ferns were the following: *Trichomanes reniforme*, the plant in perfect health, with about half a dozen fronds nearly as large as the palm of the hand, evidently put there to cause water in the mouth of every lever of ferns who should catch sight of it. *Hymenophyllum demissum*, a pretty species, like a dissected *Trichomanes radicans*. *Trichomanes anceps*, with stout, varnished, selaginella-like fronds. *Trichomanes angustata*, like a delicate, finely-divided, erect *T. radicans*. *Adiantum scutum*, a charming fern, descended from A. Farleyense, one of the best exhibition varieties known. *Davallia tenuifolia*, a very fairy-like species, most finely divided of all. *Pteris serrulata*, in a tasselled form, pretty for those who can take to it; but the varieties of this *Pteris* always appear to us worthless, though we find much to admire in a thoroughly well-grown plant of the species, weed as it is. *Stenochlæna heteromorpha*, a pretty dwarf species. *Todea superba*, indescribable in its beauty. *Lomaria gibba*, &c., &c. Yet a few more from this beautiful bank. *Gynerium argenteum variegatum* is a splendidly coloured variety; get it if you can, everybody. Whoever can get up a great plant of it out of doors will deserve a dinner, a vote of thanks, a medal, and to be talked of in whispers of adulation. *Lilium punctatum*, which may be described as *lanifolium album* refined to the last degree, the pure white tenderly spotted with palest rose. Everywhere amongst these fine plants tufts of *Nerine Fothergillii*, *Vallota purpurea*, and tall plants of the old chimney *Campanula*. A lesson this for people who, made giddy by the new possession of a few palms and ferns, begin forthwith to despise their grandmother's pets, and all else in the floral way that finds a place near the heart and angle of the cottager. Mr. B. S. Williams thinks the chimney *Campanula* one of the prettiest of plants, and—these are his own words—"shouldn't like to be without it."

PELARGONIUMS.—The show varieties of the large flowered class, the *pelargoniums par excellence* of usage, were of course not shown; they are over for the season, and there were plenty of "geraniums" instead. The botanists insist upon calling these *pelargoniums*, and we must submit; but for purposes of usefulness it is a pity we cannot pitch the botanists and their distinctions to some very far-off limbo, because, apart from diagnosis, "geranium" is a household word, and all the world knows what is meant by the term: the world knows that between *Pelargonium speciosum* and *P. zonale* and *P. inquinans* there is a vast difference in appearance, constitution, and habit of growth; and it is a pity that usage cannot in this case over-ride technical correctness; for what is technical correctness, in the case of plants so popular and so extensively cultivated, against rough-and-ready methods of making ourselves understood. Well, there were no *pelargoniums*, but plenty of geraniums in the generally-understood classification of these plants, and a very interesting point arose respecting them. But let us go on with the report, and we shall in due time come to the interesting point, and deal with it in our usual plain way. In the class for eight zonals, first, Mr. Rylance, of Aughton, near Ormskirk, with *Madame Vaucher*, *Pre-eminant*, *Bright Eye*, *Prime Minister*, *Eugénie Mezard*, *Archevêque de Paris*, *Marie Labbe*, and *Comet*. Second, Mr. Robert Barnes, of Huddersfield, with *Madame Werle*, *Rose Rondatler*, *Rev. H. Dombrain*, a fine scarlet; *Chieftain*, *Premier*, *Madame Vaucher*, *Faust*, and *Glow*, the last a beauty. Third, Messrs. Yates, of Manchester, with *Snowball*, *Bel Demonio*, *Eva*, *Volcano*, *Augusta*, *Madame Vaucher*, *Beauté du Suresne*, *Diadem*. The interesting point occurred in the class for eight variegated zonals. Here Mr. Wills, of Huntroyde, took first place with a well grown, finely-finished group, containing only one variegated plant, according to

commonly-received notions; the rest were bronze zonals, some of them with so much green in the leaf as scarcely to surpass in respect of leaf colouring the old *Commander* or *Cerise Unique*. Mr. Wills's varieties were *Bridesmaid*, a true variegated, and one of the most beautiful; *Florence*, *Rosalind*, *Radiance*, *Admiration*, *Fascination*, *Gladiator*, *Favourite*; with them were *Lilian*, *Sultan*, and some others. The second place was awarded to Mr. Watson, of St. Albans, for an extremely pretty group of gold and silver zonals, the plants smaller than Mr. Wills's, but, as respects variegation, much more properly coming within the terms of the schedule. The varieties were *United Italy*, *Amy*, *Queen's Favourite*, *Little Beauty*, *Burning Bush*, *Picturata*, *Glowworm*, *Mrs. Pollock*. Third, Messrs. Yates, with a mixed lot of no merit. The best eight nosegays came from Mr. R. Barnes, of Huddersfield; they were a poor lot, and badly labelled; the varieties were *Black Dwarf*, *Indian Yellow*, *Pink Stella*, the flowers of this shone out brightly, it is one of the first of the nosegays; *Violet Hill*, this is good; *Le Grand*, *St. George*, *Lord Palmerston* (a very bad scarlet, like the old *Compactum*, was so labelled), *Ornamental Damasus* (so labelled, the proper name probably *Magenta Nosegay*).

The only novelties shown in this section were Mr. Watson's seedling golden tricolors. *Mrs. Dix* has the merit of a nearly perfect arrangement of colours in the leaf, the tendency to present radial bars of colour being apparently reduced to a minimum. *Miss Watson*, very neat in habit, and a lively disposition of colours. *Mrs. Gladstone*, extremely bright on the margin and zone. *Enchantress*, leaf flat, pale yellow margin, zone brown, pale red, and carmine, mixing into a mulberry shade, habit very compact. *Annie Merry*, a diminutive gold zonal, which, when in good condition, has a blood-red belt, but on this occasion not in its proper colours. *Jenny Fairbairn*, a gold zonal, with flat leaf, pale yellow edge, some black and red, promising.

In other collections the following were noted as interesting—*Little Beauty*, intermediate between a gold and silver zonal, leaves much cupped, margin creamy, less red in the zone than *United Italy*. *Annie Findlay*, (Wills), a pretty gold zonal of medium habit, margin pale yellow, small green disk, zone much umber brown and bright red. *Her Majesty* (Wills), a splendid variety of the bronze zonal class, clear disk and margin of sulphur green, bold, broad, sharp zone, cinnamon deepening to chesnut. *Perilla* (Wills) a bronze zonal, fine dark zone. *Lizzie* (Wills) a beautiful gold zonal, in the way of *Mrs. Pollock*. *Princess Alice* (Wills) a bronze zonal, sulphur green, zone broad reddish crimson deepening to chesnut. *Empress Eugénie* (Wills) a bronze zonal of the finest quality, the leaf round, disk yellowish green, sharply and regularly defined, zone broad and bold, chesnut deepening to umber. *Unique*, a pretty good zonal, in the way of *Sophia Dumaresque*; the young leaves showing splendid zones of carmine, red or scarlet.

FUCHSIAS were neither plentiful nor very good. It is strange that Manchester, where stove and greenhouse plants of high character are quite in the fashion and are admirably done, such generally useful and easy things as geraniums and fuchsias should receive comparatively little attention. There are in these classes some good openings for men of spirit in the district. The best six fuchsias came from Mr. Rylance, they were neat, well flowered, rather small pyramid plants of *Prince Alfred*, *Tristram Shandy*, *Rose of Castile*, *Madame Cornelissen*, *Queen of Beauties*, *Venus de Medicis*. Second, Mr. Gresley, of Fallowfield, with *Fair Oriana*, *Prince of Orange*, *Marginata*, *Rose of Castile*, *Sir Colin Campbell*, *Sensation*. Third, E. Philippi, Esq., of Bowdon, with *Venus de Medicis*, *Schiller*, *Sensation*, *Guiding Star*, *Rose of Castile*, *Madame Cornelissen*.

DAHLIAS constituted one of the most brilliant features of this exhibition, and they were so good throughout that we could not find fault even with the stands that were not placed. The leading collections were remarkable for freshness, purity, and good staging. First for 36, Mr. Draycott, of Humberston Nursery, Leicester, with *Pauline*, *Flossy Gill*, *Vice President*, *Baron Taunton* (this is usually labelled *Baronne*, the French form for *Baroness*; there is no such title as *Baroness* here, and the flower is English and named after an English peer, *Baronne Taunton* is therefore wrong), *Bird of Passage*, *George White*, *Freemason*, *Lady M. Herbert*, *Imperial*, *Golden Gem*, *John Downie*, *Royal Robe*, *Lord Derby*, *Willie Austin*, *Harriet Tetterel*, *Leah*, *Donald Beaton*, *Fanny Purchase*, *George Wheeler*, *Miss Henshaw*, *Bob Ridley*, *Earl of Shaftesbury*, *Charlotte Dorling*, *Charles Turner*, *Lady G. Herbert*, *Hugh Miller*, *Clara Simons* (?) *Blushing Fifteen*, *Yellow Triumph*, *Lilac Queen*, *Lady Palmerston*, *Edward Sparey*, *Annie Austin*, *Lord Palmerston*, *Lord Russell*, *Lotty Atkins*. Second, Mr. May, of Hope Nurseries, Bedale, Yorkshire, with *Golden Drop*, *Lord Derby*, *Lady G. Herbert*, *Bob Ridley*, *Miss Henshaw*, *Eli*, *Peri*, *Chancellor*, *Mrs. H. Vyse*, *Hugh Miller*, *Goldfinder*, *Harry*, *Alexandra*, *Seedling*, buff and orange, good; *Mrs. Boston*, *Garibaldi*, *Miss Roberts*, *Norfolk Hero*, *Stella Colas*, *Delicata*, *Charles Turner*, *Jenny Austin*, *British Triumph*, *Lady M. Herbert*, *Charles Waters*, *Lady Popham*, *Seedling*, fine reddish buff; *Hero*, *Triomphe de Pecq*, *Surety*, *Chang* (a coarse thing not fit for a place even in a stand of 100), *Lilac Queen*, *Leah*, *Peri*, *Ebor*, *Norah Creina*, *George White*, *Pauline*, *Ne plus ultra*, *Artemus Ward*, a second-rate striped lilac, *Chaitman*, *Lady of the Lake*, *George Elliot*, *Fanny Purchase*, *Foxhunter*, *Andrew Dodds*, *Charles Turner*, *Enchantress*, *Juno*, *Miss Butler*, *Bob Ridley*, *General Jackson*, *Flambeau*, *Bullion*, *Edward Sparey*, *Bird of Passage*. Third, Mr. Rylance. In the class for 18, first, Mr. May, with *Lord Chancellor*, *Peri*, *Lord Palmerston*, *Hon. Mrs. Trotter*, *Golden Gem*, *Lord Derby*, *Lady G. Herbert*, *Bob Ridley*, *Vice President*, *Miss Henshaw*, *Charles Turner*, *Mrs. Boston*, *British Triumph*, *Lady Popham*, *Miss Roberts*, *Alexandra*, *Mr. Charles Waters*. Second, Mr. Rylance, with *Vice President*, *Queen Mah*, *Chang*, *Criterion*, *Miss Henshaw*, *Duke of Roxburgh*, *Lady Russell*, *Prince Alfred*, *Golden Gem*, *Andrew Dodds*, *Queen of Primroses*, *George White*, *Scarlet Gem*, *Mrs. Thornhill*, *Ambrose Wilde*, *Lady Jane Ellice*, *Freemason*, *Umpire*. Third, Mr. T. Painter, of Smallwood, Lawton, with *Hugh Miller*, *Andrew Dodds*, *Leah*, *Baron Taunton*, *Lord Derby*, *Pauline*, *Donald Beaton*, *Charles Turner*, *Earl of Shaftesbury*, *Lilac Queen*, *Miss Henshaw*, *Freemason*, *Lotty Atkins*, *George White*, *Lady G. Herbert*, *Fanny Purchase*, *Bob Ridley*, *Bird of Passage*. In the class for 12, first, Mr. May, with *Hugh Miller*, *Peri*, *Fanny Purchase*, *Bob Ridley*, *Goldfinder*, *Criterion*, *Miss Henshaw*, *Charles Waters*, *Charles Turner*, *British Triumph*, the best flower of this variety in the show; *Lady Popham*. Second, Mr. Draycott, with *Leah*, *Baron Taunton*, *Miss Henshaw*, *Lilac Queen*, *Charlotte Dorling*, *Lady G. Herbert*, *Hugh Miller*, *Donald Beaton*, *Annie Austin*, *Fanny Purchase*, *Bob Ridley*, *Charles Turner*.

HOLLYHOCKS were plentiful and good, some few of the contributions being of such high quality as we seldom meet with, even at the best of the southern exhibitions. The *Rev. E. Hawke*, of Willingham, took the

lead, both in spikes and cut flowers, with extraordinary examples, such, in fact, as may be most properly described as perfect. Mr. Henry May was not far in arrears of his distinguished leader in the splendour of his cut flowers. We measured a few average flowers of these two stands, and found they were exactly 10 inches from edge to edge across the face. But it was not in mere size or splendour of colours that these two collections arrested the attention and claimed the admiration of professional and non-professional visitors alike: their crowning quality was perfection of form, pockets being out of the question, and the finely-rounded surface densely and smoothly frilled, just according to the plan of an *ideal* rosette, but not like a real rosette, for no one could make one like them. First, for eighteen cut flowers, Rev. E. Hawke, of Willingham Rectory, Gainsboro', with Gem, Bidesmaid, Chairman, Prince, Acme, Ruby Queen, Seedling, straw-buff, fine; Seedling, deep crimson-red, in the style of J. B. Ullett; Willingham Defiance; Seedling, lavender, valuable for its colour, scarcely first-rate; Miss Todd, Mrs. Downie, Gladiator, Decision, Seedling, delicate straw colour, superb form; Seedling, reddish pink, splendid; Seedling, bluish purplish base, scarcely first-rate; Seedling, reddish pink, bright, distinct, fine form. Second, Mr. Henry May, of Bedale, Yorkshire, with Hercules, Mrs. McKenzie, Acme, Purple Emperor, Glory of Walden, Gem of Yellows Improved, Gladiator, William Dean, Mrs. J. Dix, Countess of Craven, Chairman, Phaeton, Mrs. Downie, Empress Eugénie, Willingham Defiance, Beauty of Mitford, Invincible. Third, and a good third, Mr. M'Indoe, of Bishopsthorpe, with Mrs. B. Cochrane, John Downie, Invincible, Lord Derby, Hercules, James Anderson, Lord Clifden, Princes, Countess of Craven, J. B. Ullett, Cygnet, John Tweedie, Mrs. Downie, Charles Eyre, Jaune d'Or, Mrs. Hastie, Glory of Walden, Purple Emperor. In other collections, fine examples of Pauline, a fine black; Mrs. Chater, lively carmine; Prince Imperial, fine carmine; Lady Helen Stewart, maroon-crimson; Queen of Buffs, Excelsior, Miss Barrett, John Bright, a fine black, with too broad a guard. Eight spikes, first, Rev. E. Hawke. These spikes averaged four feet; they were all topped and much thinned, and partially disleafed. They were solid with flowers of the finest quality, and were evidently, by the enormous thickness of the stems, cut from plants in a most vigorous state of growth. The varieties were Decision, Lady Phaeton, Willingham Defiance, and five seedlings. Second, Mr. May, with Phaeton, The Marquis, Hercules, Mrs. Chater, Emperor, Cygnet, Glory of Walden, Ochroleuca. Third, Mr. Rylance, with Tyrian Prince, Adela, Splendour, Hercules, Electra, Golden Perfection, Queen of Buffs, Warrior. The old question, if it is politic to allow seedlings to be shown with named varieties, will occur to many of our readers. Our own opinion on the subject—that seedlings and named flowers should never be staged together—has been frequently expressed. We invite attention to the subject in connexion with the foregoing particulars of the hollyhocks at this exhibition.

GLADIOLI.—In the class for thirty-six, Mr. Samuel Yates, of Manchester, with Reine Victoria, Comte de Morny, Madame Place, Madame Furtado, Diana, Jean d'Arc, Prince of Wales, Maria du Mortier, Diana, Impératrice Eugénie, Madame de Vetry, Thomas Paxton, Penelope, Monsieur A. Brogniart, Archimede, Clemence, Linné, Brencleyensis, Madame Brinder, Dr. Lindley, Milton, John Waterer, La Quintinie, Lælia, Chateaubriand, Reine Victoria, Janire. Second, Messrs. G. and W. Yates, with Walter Scott, Dr. Lindley, Reine Victoria, Mazepa, Penelope, Brencleyensis, Princess Mary of Cambridge, M. Brogniart, Lord Granville, Van Houtte, Madame Leseble, Maria, Le Poussin, Calendulescens, a nice salmon-coloured flower, scarcely at all known; Ophir, Madame Domage. First eighteen, Mr. S. Yates.

There were some tolerably good roses, but we made no note respecting them. They could scarcely have been spared from the exhibition, for they contributed much to its interest and beauty, yet there were none good enough to command praise in this report, and to speak blamefully of good endeavours is not our forte. Bouquets were shown in plenty, but there was not one that we could regard as desirable either for exhibition or actual use—the old failing, too many flowers, too much, too much of everything; the handle of the best like the handle to a bunch of water-cresses. The best was the one placed third; it was comparatively small, not overloaded with colour, neatly convex, chaste and pleasing, but surrounded with such a quantity of fern as to look as if it were stuck through the centre of a cabbage-leaf. There is nothing unkind or cynical in these remarks, ladies; you will get over the shock of severe criticism, and I hope try again. The one evil common to all failures in bouquet-making is *excess*, too many flowers, too much colour, too many fern-fronds—the result a vast aggregation, too heavy, too clumsy for the gentle hands of any sweet little miss, and the colours generally so gaudy as to clash with the colours of her dress, and sometimes make a discord.

FRUIT.—This part of the show was highly satisfactory, both as to the quantity and quality of the samples. In the class for six dishes, first, J. Dixon, Esq. (gardener, John Wallis), with two bunches Black Hamburg Grapes; two bunches Royal Vineyard, with uncommonly small berries; a fine Malvern Hall Melon, Moor Park Apricots, Jefferson Plums, Black Jamaica Pine. Second, S. Barrett, Esq. (gardener, G. D. Davis), with two bunches black Hamburg Grapes, two bunches Muscat of Alexandria, Trentham Hybrid green Melon, Apricots, Peaches, and Nectarines. Third, Lord Wharnclyffe (gardener, J. Simpson), with a fine Queen Pine, Austins' Incomparable Melon, Bellegarde Peaches, very fine Brown Turkey Figs, two bunches Black Hamburg and two White Tokay Grapes. In the class for two dishes of Black Hamburg Grapes, first, W. Jackson, Esq., M.P. (gardener, M. Woolley), large broad-shouldered bunches, highly finished in colour. Second, Earl Crawford (gardener, John Reid); here the berries were of extra size, scarcely so black as to be considered "finished," but the flavour was excellent. Third, S. Barrett, Esq., Altrincham; very highly finished indeed, beautiful to look at, but no flavour at all. There were two large bunches shown of a bright reddish-bronze colour; the flavour of these was excellent. Two bunches of any other black kind, first, J. Dixon, Esq. (gardener, John Wallis), fine samples of Black Prince. Extra, H. Broadhurst, Esq., for a fine basket of Black Hamburgs. Two bunches Muscat of Alexandria, first, Mr. A. Henderson, with bunches large, tapering, perfectly ripe, delicious in flavour. Second, E. Brooke, Esq., of Timperley (gardener, E. Milford), one bunch perfect, the other rather green. Two bunches any other kind of white grape, first, A. Henderson, Esq., with Trebbiano of immense size. Second, Buckland Sweetwater; name of exhibitor not appended. Third, Mr. Broadhurst, with Buckland Sweetwater. Four kinds of grapes, one bunch of each, first, W. Jackson, Esq., M.P., with Black Hamburg, Muscat of Alexandria, Buckland Sweetwater, and an unknown, like Lady Downes. Second, A. Henderson, Esq., of Thursby Park, with Black

Hamburg, 4 lb.; Trebbiano, 6½ lb.; Barbarossa, 7½ lb.; the last two wanted a fortnight to ripen them. Queen Pine, first, R. W. Thornton, Esq., of Sidmouth (gardener, G. Eveley), a very fine fruit, with two or three green pips. A contributor sent a very large and very coarse Thoresby Queen, which was properly taken no notice of by the judges. Any other kind, first, Mr. A. Henderson, with a beautiful fruit of Charlotte Rothschild, weighing 7 lb. Second, Mr. Thomas Booth, of Arley, with a highly-coloured Montserrat. The third place was given to a handsome Black Prince, of superb colour, but with over-ripe pips near the stalk.

Other fruits were shown in plenty. There was an abundance of vegetables and roots of the finest quality. We stop here, but without having exhausted the exhibition; for the cottagers' contributions would be worthy of a few columns, could we but spare them for the purpose. The Judges were Mr. William Dean, of Shipley; Mr. Tapley, of Chatsworth; Mr. Ewing, of Anglesea; Mr. William Thomson, of Dalkeith; Mr. B. S. Williams, of Holloway; Mr. S. Hibberd, of Stoke Newington. The attendance on the first day was large, showing the great interest felt by subscribers, in spite of the great attractions of the agricultural show only a few yards away.

S. II.

EALING, ACTON, AND HANWELL HORTICULTURAL SOCIETY.

The exhibition of this society was held on Thursday, the 29th of August, at The Elms, Acton, by the kind permission of H. B. Walmsley, Esq. At the same time visitors were permitted to ramble freely over the beautiful grounds, and the enjoyments of the day were thus enhanced considerably. There was a large attendance of visitors, and as there were a few showers the tents were occasionally very much crowded, and in consequence uncomfortably hot. The principal tent was 300 feet in length; this was devoted to the productions of gentlemen's gardeners and nurserymen. There was another tent, about half the size of the former, for amateurs and cottagers. Both were well filled; in almost all the classes the productions shown were eminently praiseworthy, and exhibitors and visitors appeared to be alike satisfied with the day's proceedings.

Amongst the more noticeable subjects were some well-grown lilioms in pots, the first prize for six being awarded to R. Attenborough, Esq., of Acton Green (gardener, T. Parsons); second, H. B. Walmsley, Esq., The Elms, Acton (gardener, R. Holliday); third, H. S. Turner, Esq., Acton, (gardener, J. Bryan). Mr. Attenborough's gardener brought a single specimen *Lilium lancifolium rubrum*, with 100 flowers in full perfection, and took the first prize in the class for single specimens. The best four balsams came from Mr. J. Long, of Ealing; they were stout, symmetrical, and smothered with fine flowers. *Petunias* were shown in beautiful condition by Mr. H. Wilkinson, of Ealing, who took first prize in this class; also by Mr. G. J. Sutton. *Fuchsias* were plentiful and good—exceedingly good. First, Rev. W. Arthur, East Acton (gardener, N. Camp), a splendid lot; second, R. Attenborough, Esq.; third, H. B. Walmsley, Esq.; fourth, J. S. Budgett, Esq. (gardener, W. Cole). *Pelargoniums* of the zonal and variegated sections were exhibited in plenty, and we particularly noticed a fine lot of miscellaneous plants from Mr. Smith, of Harlesdon House, which were not submitted to competition. Mr. Stevens presented a group of seedling tricolor-leaved *pelargoniums*, the most attractive of which were *Mrs. Stephens* and *Ealing Rival*. Messrs. Lee, of Hammersmith and Ealing, contributed liberally of orchids, cut roses, and other attractive subjects, adding thereby very much to the interest of the exhibition.

The show of fruit was highly creditable to the district, though we noticed many samples of unripe grapes. The best pot vines came from J. S. Budgett, Esq.; second,—Hinchcliff, Esq., of Acton (gardener, W. Carey). In the class for three bunches of any kind of black grapes, Mr. J. S. Budgett first, with superb samples of Black Prince, one of the best of show grapes, and as good for the dessert as for the exhibition; second, C. Lapraik, Esq., of Acton (gardener, C. Rose). In the class for three bunches of white, Muscats excepted, first, H. Blackett, Esq., of Ealing (gardener, J. I. Giles); second, R. Attenborough, Esq., with Dutch Sweetwater; third, H. T. Trautman, Esq., Twyford Abbey (gardener, J. Cooper). Very fine samples of Muscat of Alexandria were shown by J. S. Budgett, Esq. The heaviest bunch of any kind came from J. H. Buchan, Esq. (gardener, G. Vennier), the variety Black Hamburg, weight 2 lb. 9 ozs.; second, R. Yeo, Esq. (gardener, E. Marcham). Fine pines were shown by H. B. Walmsley, Esq., first; and J. S. Budgett, Esq., second. Six peaches: first, S. Tiddesley, Esq. (gardener, R. James); second, S. Turner, Esq. (gardener, J. Bryan); third, H. Blackett, Esq., these were finer fruit than the second-prize lot, but wanting in colour; equal fourth, F. Hamilton, Esq. (gardener, J. Belcher), and H. Wilkinson, Esq. (gardener, J. Sutton). Six nectarines: first, J. Smith, Esq. (gardener, Mr. Edwards); second, R. Attenborough, Esq.; third, Captain Tyrrell, R.N. (gardener, Mr. Hall). One scarlet-flesh melon: first, D. Lapraik, Esq., the smallest melon in the show, but very highly coloured; second, E. Oates, Esq. (gardener, R. Marcham); third, R. Attenborough, Esq. One green-flesh melon: first, E. Oates, Esq.; second, H. Wilkinson, Esq.; third, J. Smith. Six dishes of fruit: first, C. Watson, Esq. (gardener, C. Smith), with greengage plums, pears, cherries, &c., all extra fine; second, E. Wood, Esq. (gardener, F. Prece), in this lot red currants good; third, Rev. J. North (gardener, Mr. Boswell); fourth, R. Attenborough, Esq., in this lot a dish of Pond's seedling plums as large as hens' eggs and full ripe.

In the amateurs' and cottagers' tent, abundance of good flowers, fruits, and vegetables. The prizes in some of these classes were awarded by the Baroness Rothschild, the Hon. Mrs. Walpole, and Mrs. Budgett. The highest praise is due to Mr. E. Marcham for the admirable staging of the subjects shown, and also to Mr. Weatherly, the indefatigable honorary secretary.

MAMMOTHS AD LIBITUM.—About 40,000 pounds of fossil ivory—that is to say, the tusks of at least 100 mammoths—are bartered for every year in New Siberia. As many as ten tusks have been found lying together in the "Tundra," weighing from 150 lb. to 300 lb. each. Notwithstanding the enormous amount already carried away, the stores of fossil ivory do not appear to diminish. The mammoths appear to have been suddenly enveloped in ice or to have sunk into mud which was on the point of congealing, and which, before the process of decay could commence, froze around the bodies and preserved them in the condition in which they perished.

STRIKING VERBENAS IN BOTTOM HEAT.

I will not stop to inquire whether the old adage of "better late than never" is equally applicable to operations appertaining to the garden as it is to other social affairs, but pass on to the practical part of this paper, for I have no doubt that I shall be thought by many to be frightfully behind-hand in writing about Verbenas at the end of August. Be that as it may, I admit that it is rather late, but, at the same time, there are hundreds, nay, thousands, who have not done more than make a commencement towards providing for next year's display. It would be no matter to me if there were no more than fifty, or that the late birds could be counted by units instead of tens, provided my advice enabled them to get up a few thousand Verbenas without one half the trouble which is usually employed in that operation at this season of the year. What I mean by half the trouble is simply to strike 95 per cent., instead of from 20 to 50, which is most unquestionably a vast difference, and also a matter of some importance. The 95 represent what can be struck with the assistance of a nice, sweet, gentle bottom heat, and the 20 to 50 will represent those cuttings which will be rooted in a cold frame. I am not speaking at random, or overstating the number on the one hand, or understating it on the other, presuming, of course, that the most careful attention is bestowed upon the cuttings in both cases.

I am well aware that very few gardeners think of making up a hot-bed for propagating purposes in the autumn, a fact which goes a very long way indeed to account for there being so many inquiries respecting each other's success in this respect, and the frequency of the remark that the Verbenas are doing badly and going off by wholesale. I am unable to see any great difficulty to prevent us from arriving at the cause at once. Generally speaking, we contrive to give cuttings a greater degree of warmth to the soil in which they are placed, even if we do not increase the atmospheric temperature, than the plant from which they were taken enjoys. For instance, we do it in the spring in the propagation of the usual stuff employed in bedding out, and it is attended with the most beneficial results, and I am certain that equal success would follow were it employed in the autumn. It may be recollected what a difficulty there was to get Verbenas to root three years ago this autumn, and what a cry-out there was about them the following spring. That year I made a hot-bed up expressly for them, and I am certain I never saw a better autumn-struck lot in my life; not more than 5 per cent. of the cuttings perished, a number which it will be admitted was very small. To anyone who requires several thousand it is a matter of importance, and also of time, if he puts in two thousand cuttings for every thousand plants that he wants, while on the other hand he can depend with the greatest certainty upon 90 plants for every hundred cuttings, if he chooses to make up a hotbed for the purpose. The bottom heat is not required to be so strong as it is usually employed in the spring. I shall not go into the routine of the whole process, but remark, that as soon as the cuttings are rooted they should be shifted from the hotbed and gradually hardened off, for if they remain in heat too long, they naturally enough will be tender and unable to stand the cold and damp through the winter, and I am no advocate for coddling them after I can once get some roots on them.

GEORGE GORDON.

NOTES ON FUCHSIAS OF 1866.

We are annually having new varieties of Fuchsias introduced into cultivation, and until they become generally grown, we can know but little of their several habits or adaptations for the purposes for which the purchasers may require them. The descriptions given of them in the nurserymen's catalogues, in the first instance, are but transcripts of the raiser's own words respecting them. Any other particulars that may be afterwards afforded by other growers must be acceptable to those who are anxious to become acquainted with their respective claims, either as plants for the conservatory or for exhibition—not that we doubt the veracity of the raiser's words concerning his own seedlings, only we must not be unmindful of the saying, that "Every parent considers his own child the very gem of children." Influenced by these considerations, I venture to offer a few remarks on twelve varieties of Fuchsias introduced in 1866. But before I proceed, let me say that the plants which are the subjects of my task were not purchased till the early part of the spring of the year. They were then well established in small 48-size pots, and from them they were transferred into 24 or 8-inch size pots and plunged in cocoa-nut fibre in a pit, which afforded them both bottom and top heat. Every attention was bestowed on the watering and syringing them till they showed flower, when they were removed to their blooming house. We will commence with—

Alexandrina (Banks).—This is perhaps as rapid a grower as any variety in cultivation, and somewhat after the style of that once popular sort *Venus de Médis*. As it progresses in growth, it extends its branches from every eye of the main stem. Thus it forms a complete pyramid, gradually expanding in dimensions from the top to the bottom of the plant. Although but a few inches in height in the spring, it has now attained that of five feet. It is very free to bloom, and is now, after a short pause, producing a second crop of flowers. It has a white corolla with a scarlet tube;

the flowers are of medium size. I believe that it would prove a fine variety for training up the pillars inside a conservatory. That you may give density to its growth, continue to stop or pinch its side shoots in the earlier stages.

Arabella.—This is a noble flower, with white tube and sepals, and as one of the large flowering light varieties, it is an invaluable acquisition. It is a very free bloomer, comes in early, and continues throughout the season. It is a strong grower, and should be pushed on, if required to attain a good size, on account of its predisposition to flower early; it is inclined to be tall, with a fine branching or pyramid habit.

Blanchette.—The flower of this light variety is very fine, and of a colour much needed, viz., white tube and sepals, with a bright rose-coloured corolla, reminding one of that good old variety *Cléo*. I cannot say anything in favour of its habit, although the description in the catalogues speaks very favourably of it. With me it has made very indifferent growth, but has shown every disposition to flower profusely.

Catherine Parr.—This excellent variety cannot be cultivated too extensively either for ornamental or exhibition purposes. Although the flowers are but of medium size, yet they are produced in great profusion, and continue throughout the season. The colour of the flower is very pleasing, being white tube and sepals, with a bright scarlet-rose corolla. Its habit is first-rate as a good branching pyramid.

Lizzie Hexham.—This is a very good dark variety; a very free bloomer. The habit is also first-class; but that you may obtain a well grown specimen, you should commence to grow it early, say some time in November or December. If subjected to a nice intermediate moist heat it will grow rapidly.

Ben-e-Gloe.—This is a very dwarf variety, does not require so much pot room as the more rapid growers. It is a first-rate variety for the centre of a table. Not only is its habit dwarf, but it is also very bushy, with short-jointed wood, somewhat similar in its growth, though much dwarfer, to *Bo-peep*, which was a great favourite in its day, and not now to be despised. The colour of the flower is very striking, bright scarlet sepal, with a corolla of glowing dark lavender. Altogether it is a very desirable variety and free bloomer; valuable, too, for its distinctiveness.

Conquest.—This is a very pretty dark variety; very free bloomer. The flowers are not large, but they are very attractive, and finely reflexed. With care will form a nice pyramid.

Lady Dumbello.—Too much cannot be said in praise of this flower, for it is both grand in size and colour, being very long and wide, with scarlet reflexed sepals, and a rich lavender or blue corolla. It is of very bushy habit, but makes very long shoots. It is more suitable to grow as a bush than as a single stem pyramid. It is of a moderate height, and a very profuse bloomer, but does not flower till late in the season.

Harry George Henderson.—Not so good a bloomer as the preceding variety, although a very noble and effective flower. The shoots are long and erect. I do not think any coaxing on the part of the cultivator would induce it to become a good single stem branching pyramid. Its colour is very attractive, being a bright scarlet with a rich plum-coloured corolla.

Julia de Guest.—We may rank this with the two latter varieties as regards the season of blooming, the trio being decidedly autumnal flowering plants, and as such are a great acquisition to the list of good fuchsias. This variety is a very strong grower, and remarkably free to bloom, producing long erect shoots, furnished with plenty of bright red flowers with the addition of a beautiful lavender blue corolla. For style of growth and period of flowering, the three last-named may be considered to be of equal merit.

Beauty's Bloom.—A very pleasing dark free-flowering variety, of medium size. Habit good; with early attention the plant would make a unique specimen. This we can employ for table or decoration; it is very dwarf, with a nice compact habit, and forms naturally a pyramid shape. Its branches gracefully hang over the sides of the pot, so that when slightly elevated its fine white double corollad flowers are seen to advantage.

The observations which I now offer are entirely from notes I have made of the respective varieties in bloom, thinking they may assist those who are anxious to make choice of good and useful varieties of this popular flower.

JNO. F. McELROY.

ON PLANTING STRAWBERRIES IN SPRING.

Some advise strawberries to be planted in the end of August, or in September, or, better still, between the 1st and 15th of October; others prefer the months of March or April. Those who advocate the former period say that the plants put out in the end of summer or beginning of autumn have time to establish themselves in the soil before winter, and to gain sufficient strength to bear a crop in the following summer. This reasoning, it must be admitted, appears plausible. The success of plantations made at this season depends, however, in a great measure, on the soil being well worked, and in proper condition as regards moisture; on the plants being sufficiently strong and furnished with good roots, and on their being carefully transplanted. I agree with the opinion of those who prefer spring planting. For more than a quarter of a century I have planted at all seasons, but the spring plantations have always proved the best. The cause of this success lies in the following facts.

The plants established round the stools since last summer, without being detached from their parent plant, will be found much stronger after winter than those that have been separated before winter, either for planting out in nursing beds, or at once in the plantation. When carefully taken up with their fibres in spring, they soon take root, and grow vigorously in well-prepared, newly-dug ground; and in June or July they produce as much fruit as those that have been detached in a young state and planted before winter.

On taking up some young strawberry plants, it will be observed that the very slender fibrous roots extend obliquely in the soil in all directions round the parent plant. From this fact the cultivator should infer that in transplanting he ought to extend the roots in a similar oblique direction, covering them successively with soil up to the necks of the plants. On examining these a fortnight after, it will be found that new spongioles have been formed all along the roots, a circumstance which shows the utility of preserving all the fibres when taking up the plants.

Every cultivator must be aware that strawberries push roots more than a foot into the ground, provided it is deep, and rendered loose and permeable by manures suitable to the nature of the soil. They extend obliquely more than a foot and a half in all directions round the plant. If they are planted so closely that the roots entangle each other in struggling to obtain nourishment, it may be easily conceived that the produce must in consequence be diminished, not only in the first, but also in the second, and more especially

in the third year after planting. By some this is ascribed to the plants being exhausted; but this is an error arising from mistaking the effect for the cause. It would be more reasonable to say that the elements of nutrition in the soil become insufficient for the demand. These observations show the necessity of planting widely apart, so as to prevent the roots of strawberries and other plants from coming in contact with each other, if we wish to obtain fine produce.

Those who plant exclusively with a view to crop, and to obtain the fruit in full perfection, cut off the runners in spring and summer as they are produced. The fewer runners a variety of strawberry throws out, the easier the plantation is kept in order. A variety naturally disposed to make few runners is preferred to those that produce many, if in other respects it possesses equal merit, a property which is becoming more and more appreciated by connoisseurs. The limited production of runners is considered a fault of *La Constante*; and this is a reproach thrown on this strawberry which is even not well founded, for if planted in good soil, neither too dry nor too stiff, cold, and wet, it produces runners sufficiently well. A dozen young plants, which were planted out in August, 1862, furnished by October 127 plants, which was at the rate of more than 1,000 per cent. The circumstance of this variety not producing a superabundance of runners is considered one of its meritorious characters by the most intelligent cultivators.

J. DE JONGHE.

[The foregoing is reproduced from another work, in compliance with pressing requests from several correspondents.]

THE BEDDING DISPLAY AT VICTORIA PARK.

The flowers in Victoria Park have for a long time past attracted thousands and thousands of persons from the eastern parts of London to enjoy a cheap festival in the open air, and witness how great are the triumphs of art in embellishing the face of nature. Generally speaking, the schemes of colouring are rich and satisfactory, in one notable instance particularly so; and though some things have flowered out and become rather weedy-looking, the display will continue bright and good for several weeks to come, should the weather prove favourable. Indeed, such things as *Coleus*, *Amaranthus*, *Dahlias*, and sub-tropical plants, have but just now acquired their proper characters, so unfavourable was the weather all through the earlier portion of the summer. During that cool time the *calceolarias* attained their maximum of splendour, which is now past, and cannot be revived this season; yet the *calceolarias* are tolerably flowery even now, and there have not been many deaths in the beds, an immunity which may be accounted for perhaps by the richness and usually moist condition of the soil here. The mellow fertile loam of Victoria Park suits the *calceolaria* admirably, and they have no need of the six inches of rotten manure which constitutes my golden recipe for keeping them alive and well on soils where they commonly refuse to live in a dry season.

Some very interesting facts may be gathered about beds and bedding at Victoria Park just now; for example, *Coleus Verachaffeltii* has been as black as a bad hat (a once black hat, of course) all the season till this present, and now it has its true character—a rich modulation of crimson and chocolate, with a soft tinge of violet on the top. *Amaranthus melancholicus* has been brilliant from the first, the best perhaps of all known foliage bedders; but now it has acquired a deeper hue than ordinary, a blackish tone in fact, but which does not spoil it, nay, rather improves it when its relief agent is some good golden or silvery leaf. *Iresene* is not much used here, but that is everywhere beautiful now, and our once discarded plants at Stoke Newington have “picked up;” the solar heat has cured their malady—a sort of slow consumption—and when seen against the sunlight, the colouring is just of that “stained-glass” character that I ventured to describe it on its advent to the bedding world. In respect of edgings, the *Dactylis* carries the day at Victoria Park against the *Poa trivialis*; but Mr. Prestoe has a notion—a good notion—of using it for edgings, and *keeping it clipped*. This will stop its seeding, and keep it down to a close line; for its tendency is to grow more upright, less like a mat, than the variegated *Dactylis*. In the matter of geraniums, let every visitor to this interesting place take note of Lord Palmerston. It may be seen everywhere, in fine solid self beds and in combinations; and though it is not one of the sorts that we ought to look close at and down upon, as we do with Mrs. Pollock, it is grand when seen from a proper point, and we may say of it, as Campbell says in the opening of his “Pleasures of Hope,” that “distance lends enchantment to the view.” Here, too, *Attraction*, prince of scarlets, is fine, splendid; the beds are paved with big leaves that form a groundwork for splendid trusses of scarlet flowers. It is as flowery as Tom Thumb, and the flowers have quality, which most of the popular scarlets are deficient of. *Commander*, *Cerise Unique*, and *Stella*, are all equal to their high repute; but *Cybiater* disappoints me, and in the great semicircular scheme it may be judged well, and it will be seen to be weak as compared with *Stella*, which has immense power, in the same scheme; more power probably of colour—and right regal colour—than any other known geranium. *Phlox Drummondii* has been less used than in former years, and *Gazania splendens*, usually a favourite here, is scarce. These circumstances have nothing to do with the intrinsic merits of those plants; they are the results of accident, matters of local and not general import. Another matter worthy of a special note is that *Dianthus Heddwegii* is largely used, and remarkably well done. I could pick out many a first-rate florist's flower amongst them, and the poorest in quality are nevertheless gay in colour, and fulfil all the conditions required of a bedding plant.

In the issues of the Magazine for August 4th and 11th, of last year, will be found our report on the bedding in 1866, accompanied with some large diagrams of the principal schemes. I shall not now attempt to describe every bed, but shall touch upon as many of the more prominent features as will render this number of the Magazine useful as a guide to the colouring for those who can see it, and I hope useful also to those who cannot. I will ask the reader to refer to the figures and descriptions published last year; and now we will take our stand somewhere on the road which connects together the Crown and Royal Hotels, and which, if I remember right, has been described in former reports as Llanover Road. But no matter, the two hotels are as well-known in the district as Aldgate Pump is known elsewhere, and in a place of such vast dimensions it is better to select a position for reference about which there can be no mistake, for to see the bedding the visitor must find this road or be disappointed. Now, on the way from the Crown to the Royal is a continuous shrubbery on the right. The shrubbery approaches and recedes so as to form bays and inlets, and it is finished off with a waving line of ribbon, which consists of front row *Calceolaria Gem*, and next line *Stella*, which to my eye is a very unhappy

combination, for the deep dull orange-red of the *Calceolaria* is overpowered by *Stella*, and on the other hand *Stella* is muddled by the discordant combination. The first gap we reach after leaving the Crown contains a splendid bed. It is a circle divided by a great cross of *Centaurea ragusina*, the angles filled in with *Coleus*, the edge *Cloth-of-Gold*. Draw a circle, divide it into four quarters by lines at right angles through the centre, and you have the simple plan of a great bedding success.

Presently, as we proceed, we arrive at the great bay whereon is the double scroll and group of beds, figured at page 360 of last year (August 11, 1866). Contrary to the prevailing rule, this looks poor on paper, as the print will prove, but on the ground it is grand, and a view of it lengthwise is better than a view across from the centre on the pathway, though the last is the view which must be considered most proper. The scroll has for edgings on both sides *Lobelia Paxtoniana*, and central line of *Little David geranium*. The central circular bed opposite the point where the two scrolls meet is *Treatham Roae* alone, a broad sheet of colour not surpassed for richness, freshness, and completeness by anything else in the Park. On either hand two circular beds, consisting of *Calceolaria aurantia* edged with *Lord Palmerston geranium*, a charming combination, and a better balance than *Calceolaria* and *Christine*. At each extreme, right and left of the scroll, lozenge-shaped beds, with *Christine* centre, *Flower of Spring* all round, and edging of *Amaranthus melancholicus*. Again, further outwards, a pair of circular beds, consisting of *Punch*, with *Amaranthus* edging. At the extreme ends of the design lozenge-shaped beds of *Christine*, edged with *Lobelia Paxtoniana*. Next the shrubbery are some small beds, consisting of *Calceolaria Gem* alone, and yellow *Calceolaria* edged with *Perilla*. There is a richness and completeness about this colouring that will delight all who see it, so far as they are capable of discriminating good and bad. I do not say that it surpasses the colouring of last year, when *Cerastium* brought out the scroll very brightly; but it is warmer, and there is not a single improvement to desire.

To the left of this scheme is a pleasant walk beside the ornamental water to a place of shade and rest. All sorts of good things may be found accompanying this walk. There is a group of beds on the right, or, if you keep to the road which connects the Crown and the Royal, you see the same beds on the left, for they lie between the bye-walk and the drive. But we are on the walk, and we observe that one bed in particular is attractive and striking. It is a large oval, filled with *Centaurea ragusina*, and edged with *Perilla*. All around the beds are highly coloured, else this one would be cold; but in its place it contrasts pleasingly with rich masses of scarlet, yellow, and purple, and may be made a note of as well adapted to serve as a decided neutral agent in a scheme of strong colouring. Here will be seen a front waving line to finish off the shrubbery consisting of variegated coltsfoot *planted out* (which accounts for the huge leaves they have made; this plant is usually plunged to prevent its rambling), behind the coltsfoot *Calceolaria Gem*, and behind that the old *Prince's Feather*, a sort of lively funeral plant when seen associated with ordinary bedders, but a plant not to be despised, for its very heaviness is a help to gay things. Observe on the left, going toward the resting-place, a splendid specimen of *Aralia Sieboldii*, observe everywhere how fine the tufts of *Indian Corn* look; observe the isolated beds of tobacco-plants in bloom: they are not gorgeous, but very useful; for it is well the east-enders, who smoke and spit considerably, should see the plant that does so much to make them pale, and renders them liberal pecuniary supporters of the state, through the medium of the revenue. At the corner of the side-walk that conducts the weary traveller to a place of repose is a nice plant of *Aralia spinosa*, in perfect health and growing freely. It stood there all the past winter, got cut back a little, but has quite made up its loss by a vigorous new growth.

The way I go may actually suit no one but myself; but I go the way I am led, for I never trust myself to find my way about a place of this sort. I might, as somebody in the versifying line says,

See the summer daylight fall,
And leave half told the pleasing tale.

That is to say, I might wander all day from the objects of my search, and at nightfall be nowhere. So I allowed my conductor to take me towards the Crown, but not to take me to it. At the gate we turned round to the right, and behold we were in the “Avenue,” one of the prettiest drives in the place, with a great sweep of ornamental water, and one of the finest collections of willows in the world, on the right of you. On the left a series of bays, in every bay a scroll, the borders beyond filled with herbaceous plants, which, I must say, are not of the best; there are too many weedy kinds of *Calliopsis* there. Perhaps a hundred good hollies dotted along the front line of that border would improve it much. Scroll No. 1 has a centre line of *Little David*, edged on both sides with *Lobelia Paxtoniana*, pretty. Scroll No. 2, diagonal bars of *Little David*, blue *Lobelia*, *Amaranthus*, *Lobelia Paxtoniana*, *Little David*, and so on again; don't like it. Scroll No. 3, centre line of *Lord Palmerston*; on each side of it *Calceolaria Gem*, edging of *Cineraria maritima*; bad. Scroll No. 4, centre line of *Christine*, line each side of *Calceolaria Amplexicaulis*, edging of blue *Lobelia*; this is nothing now, for the rain has washed away the flowers, and the *Calceolaria* will not make many more. But I will prophecy backwards that it has been one of the prettiest scrolls in the place; it must have been; wish I had seen it a month ago. No matter; put this down as a good scroll, and you will be safe. Here is the beautiful arcade, a most cosy retreat, pretty well occupied with humble folk: what a blessing for such to have a place of rest fit for a Sultan, and therefrom to look upon a scene so beautiful, and teachable, and comforting, as that smooth lake, with its swans and islands, boats and trees, sunshine and shadows! If this appears too gushing in style, go and see the *people* as well as the park; you will not be long in concluding that hard toil and poverty, and perhaps some demoralizing influences from which the east of London is not quite free, war with terrible energy against the creature that was formed in the image of God. Mind you, towards evening the park is crowded with a very merry population. The East End can turn out its plump holiday-makers, as well as its emaciated representatives of the social miseries for which it has an unenviable fame.

By a turn round to the right from the top of the Avenue, we come upon the display at Shore Place, which is the most select district of the park. Please turn about here and view things leisurely. Nothing elaborate, curious, or difficult, but much beauty and the place well kept. Always a grand waving ribbon here, and now we have a good one to sustain the fame of the spot, and of its master, Mr. Prestoe. Front line, *Lobelia Paxtoniana*; next line, *Variegated Dactylis*; next line, *Calceolaria aurantia*; next *Stella*, next *Captain Ingram Dahlia* (there are people who suppose the *Captain*,

once most popular of bedding dahlias, extinct, not so—go and see it); next mixed Dahlias, and beyond a rich mixture of shrubs and trees. Standing somewhere towards the gate at Shore Place, you see two low mounds. The one on the right was figured last year, at page 347 (Aug. 4th, 1866). This mound is now planted in a succession of scrolls, consisting of blue Lobelia. Where the scrolls meet are dots of Baron Riccasoli, and Cloth-of-Gold. The bank is filled in with a groundwork of *Gnaphalium lanatum*. The top line is Lord Palmerston, the bottom line *Amaranthus melancholicus*. I fancy a blaze of scarlet would look well there, the beautiful ribbon leading up to it well; but as it is, let us be content and thankful for so much beauty. The mound on the left is in a series of festoons of Flower of Spring, enclosing semicircles of Lord Palmerston, *Calceolaria Amplexicaulis*, *Stella*, *Christine*, *Centauria ragasina*; the filling-in below is blue Lobelia, the margin white Alyssum. Several very distinctive and beautiful beds about here. Observe one large circle divided into six parts from the centre, the divisions in pairs, one pair Brilliant, one pair *Calceolaria aurantia*, one pair *Amaranthus melancholicus*; the edging *Gnaphalium lanatum*. Everywhere about beautiful top lines of *Dahlia albana*, one of the best, and now at its best, and likely to keep so for some time to come.

Let us now go up the road towards the Crown again, and observe various things on the left of the drive. Oblong bed of *Verbena Grand Boule de Neige*, edged with blue Lobelia, good. Oblong bed of *Tropaeolum compactum*, with leaves the size of a florin or less, and smothered with small orange-red flowers, edged with blue Lobelia, splendid. The great mound, which has usually been planted with *Phlox Drummondii*, is this year in mixed Dahlias, edged with *Phlox*. The latter is breaking up, but the Dahlias are all right; a bold affair. Oblong of *Christine*, edged with *Heliotrope Muleteer*, a good purple kind. Oblong of *Amaranthus melancholicus*, edged with *Viola cornuta*, good; yet the *Viola* not half so flowery as at Manchester, and anywhere and everywhere in the Midland counties and the North. Oblong of *Petunia Alba magna*, edged with a small *Achillea*, the *Petunia* fine. Oblong of *Dianthus Heddelegi*, equal to the best bed of Sweet Williams, and just in that style, except that the flowers are larger, and the Sweet Williams have done blooming long ago. Now we come upon the great semicircular scheme, which is as grand as can be,—enough red to give it richness, and enough of other colours and contrasts to draw it out to its full dimensions, and demonstrate all its parts.

This great scheme is represented true to scale at page 348 of last year (August 4, 1866). The key to it is the bird or butterfly in the centre next the drive. From this point we see in every direction, right, left, and forward, alternations of colour that in every way help each other, and there is not a hitch anywhere, which is great praise for so large a system, and one so disadvantageously placed in respect of the absence of architectural accessories. I think it is better coloured this year than I have ever seen it before, and you will find in the reports of the past six years that I have sometimes found fault with it by that process of hypercriticism on which these reports proceed,—the vice of the dilettante who splits a hair to discover if one side is in any way different to its fellow. The two wings of the butterfly are of Baron Riccasoli, with dots of Cloth-of-Gold; the tail of the butterfly is Cloth-of-Gold, the body of the butterfly is a round dot of Cloth-of-Gold; the edging is *Cerastium tomentosum*. On each side the butterfly right and left, next the drive, round beds of Scarlet *Verbena*, very much like one that Messrs. Low and Co. have under the name (apocryphal) of James Shaw; at all events, a splendid scarlet. In the semicircle which these *verbena* beds commence, the next beds are oblongs of *Petunia Alba magna*, splendid. Next, in the same semicircle, round beds of a seedling *Petunia* of Mr. Prestoe's, the colour soft rose; this is a good one. The keystone to the arch of the centre bed of this series consists of blocks of *Alma* filled in with *Amaranthus melancholicus*.

Beginning again next the drive in the semicircle next following outwards, oblong beds of Purple King *Verbena*, edged with *Cerastium tomentosum*. Next circular beds of *Tropaeolum compactum*. Next oblongs of *Calceolaria Prince of Orange*, edged with *Geranium Brilliant*. Circles of Lord Palmerston, edged with the *Dactylis*. Key bed of *Cybister*.

Begin again, and in the same way, with round bed of *Lobelia Paxtoniana*. Next oblongs with four blocks of *Christine*, filled in with *Calceolaria Aurantia*; very cheerful and sound. Oblongs again of *Stella*, edged with variegated coltsfoot; a wonderful pair of beds, improved by the distance, and led up too skilfully over the white *Petunia*, the rosy *Petunia*, and the orange *Calceolaria*. Oblongs again of *Calceolaria aurantia*, edged with *amaranthus*. It scarcely matters out here what the beds are edged with; the big blocks of colour are the visible constituents of the display.

In the outermost of all the semicircles, the planting is as follows:—oblongs next the drive, variegated Alyssum and Flower of the Day mixed for a groundwork; the edging *Amaranthus*. Next circles of Brilliant. Next oblongs of *Calceolaria Amplexicaulis*; band all round of *Calceolaria Gem*; edging of *Dactylis*. Circles of *Trentham Rose*. Oblongs of *Punch*, edged with *Perilla*. Circles of the "Variegated Ribbon Grass," *Phalaris arundinacea*, edged *Cineraria maritima*, the two grays blending when seen from the drive, and serving admirably as gray blotches to carry the eye round the boundary beds. Key of the arch, *Trentham Rose*, a glorious bed, well worthy of its position, and in every way a fine finish to Mr. Prestoe's best work of the season.

The curtain ought to fall here, for though we may go on and find beds and borders everywhere, and when tired of colour find a feast in a criticism of the trees, there is nothing of import sufficient to detain us longer on the present occasion. The triangle hard by is in a quite different style to the scheme, it will be observed; so are the beds and borders on the opposite side of the road. And, by the way, there is an exceedingly good ribbon on the other side, which will not bear close inspection, but viewed as a ribbon is unique. The front line is Variegated Coltsfoot; next, *Amaranthus melancholicus*; next, *Calceolaria Amplexicaulis*; next, *Geranium Trentham Scarlet* (syn., *Crystal Palace Scarlet*); next, *Perilla*, top line mixed Dahlias. The *Perilla* comes out well in this, and the *Amaranthus* balances it perfectly.

S. H.

Calendar.

WORK FOR WEEK COMMENCING SEPTEMBER 7.

Kitchen Garden and Frame Ground.

ARREARS must be fetched up, or the fogs and morning frosts will overtake something that has been too long delayed. Refer back to notices of the past few weeks, and especially be on the alert to propagate whatever has been neglected hitherto.

CAULIFLOWER AND BROCCOLI to be planted in quantity for spring use, and rather close, that the plants may protect each other; and in case of hard weather all except the outside rows may escape injury. Recently-sown stock should now be in rough leaves, and should be pricked out in frames or small clumps, to be covered with hand-glasses. A few of each of the kinds of cauliflower should be potted to keep in frames all winter.

LETTUCES to be sown to stand the winter, if not done already. Choose a sheltered piece of well-drained ground. Those sown three weeks since to be planted out under walls or in patches, to be protected with hand-lights.

MUSHROOMS.—Prepare the bed for winter supply. The first thing to be done is to collect plenty of short unfermented dung, or if only long dung can be had, pick out the long straw and lay it in small heaps to ferment gently, and turn it every three or four days till it produces only a gentle heat, then make up the bed. A dry dark shed is as good a place as any, but a better crop and a larger supply may be ensured where the beds can be made over a warm chamber.

POTATOES left in the ground after this time will spoil faster than they grow; get them up and stored; and should you intend to follow the practice of autumn planting, throw out all the middle-sized greenish tubers, and plant them at once, seven inches deep, and the rows not less than thirty inches apart.

Flower Garden

AURICULAS.—Look over the whole stock, and stir the surface of the soil in the pots, and remove dead leaves. If any leaves are damaged, turn the plants upside down and search for insects. If any green-fly is visible, shake some dry silver-sand among them, and blow it out with force, and the vermin will be carried away.

BEDDING PLANTS struck now should be potted singly and shut up close in frames. It is too late now to put cuttings in the open border, as the ground is cooling and the plants are sappy, owing to the late abundance of rain. All the bedding stock that is now well rooted and potted off for winter should be placed out of doors on a hard bottom of stone or slates, to harden for three or four weeks.

BULBS to be planted. Those most important now are Snowdrops, Crocuses, and Narcissus, and hardy border Lilies, as these do no good if kept long out of the ground. Pot Hyacinths, early Tulips, Narcissus bulbocodium, *Tritonea aurea*, *Ixia*, and *Sparaxis*.

CALCEOLARIAS may be propagated now in quantity; they need no bottom-heat. Take short stubby side-shoots, dibble them into a mixture of leaf, very rotten dung, and about a fourth part sand. They strike quickly, and make fine strong plants in cocoa-nut waste well rotted; so if the plunged bed can be cleared out, the rotten cocoa waste will be the best stuff that can be used for them; they will readily root now, and make first-rate plants for next season. Put in plenty of short stubby side-shoots, and shut up in a frame.

HARDY ANNUALS may still be sown to keep over winter. If sown in the open ground, it must be on poor hard soil, in a dry position. We named the best sorts a fortnight since, and may now repeat that all the really hardy annuals are better from autumn than spring sowings.

HOLLYHOCKS to be cut down as soon as they have bloomed out. Any very choice, from which cuttings are required, to be cut down without waiting for the last blooms to open, as it is important to gain a week or so to get good breaks from the stool to cut from.

CLEMATISES are now in their full splendour, and a few words about them may be useful. *Clematis lanuginosa*, *C. azurea grandiflora*, and others, have long graced our gardens, and are remarkable for their enormous flowers of various shades of blue; but it is only within the past few years that numerous striking varieties of the family have been noticed at our shows, in various shades of blue and rich dark purple. They are so attractive in appearance and noble in flower that doubtless many of our readers have been induced to purchase young plants, and therefore a few words on their culture may not be amiss. They are, when well grown and flowered, the noblest of all climbers for walls, trellises, or any other position in which hardy climbers may be desired. We have seen them flourish freely planted on the level ground, and allowed to stroll over it in their own way. On trellised arches which one occasionally sees in gardens, on the slender wirework fence so often used of late, they are truly beautiful and effective. They, like most things that we have to treat of, enjoy a good rich soil, and if with that it is light and free, so much the better. If the soil is very heavy, it had better be made light by the admixture of road-sand, leaf-mould, and other matters which may be convenient before planting; if light, it must be well deepened and enriched with rotten manure and stiffish loam, if convenient; but, no matter what the soil may be, the secret of cultivating these clematisses is to give them a few inches of well-rotted manure, on the surface of the earth all round where the roots are, or, in other words, to "mulch" them. If the appearance of the manure is objected to, as it may be by many, it may be covered with an inch of soil, and on that some annual, like the aster, may be grown for the summer months. As regards training, they are best left alone in summer, at least till the shoots get very long indeed; but during the winter months they must be firmly tied or nailed over whatever surface they occupy, as the weight of flowers is considerable where they are properly grown, and by having the main shoots firmly secured, the rich mass of blooms, many of them as large and larger than tea-saucers, may be allowed to hang down in a graceful and natural manner, which much increases the beauty of the plants and whatever position they adorn. It is almost useless to enumerate any special kinds among those new hybrids and varieties sent out by Messrs. Jackman, as all are good, and it is only necessary to pick out the most diverse; and in many gardens where climbers are much valued, all the varieties will be acceptable. Where we write this is a splendid plant of *C. Jackmannii*, every shoot suspending a range of noble rich violet flowers, and several dozen other kinds, large and small, and all nearly

SUBSCRIBERS TO THE GARDENER'S MAGAZINE who desire to extend its sphere of usefulness, and are willing to interest themselves in promoting its still wider circulation, can materially further this object by sending to the publisher the names and addresses of persons they think are likely to become subscribers, who will forward to each a SPECIMEN COPY free. A stamp must accompany each name and address sent, to cover the postage of the specimen copy.

equally beautiful and equally appreciated. The small kinds, like *C. viorna*, with its pale pink flowers; *C. Shillingii*, with its very delicate ones; *C. flammula*, with its mass of fragrant spray,—cover arches beautifully, and look effective in the mass; while here and there the splendid single flowers of such kinds as *C. rubro violacea* catch the eyes of many who hardly ever notice a flower. Those who plant clematises should never by any chance omit the beautiful large-flowered variety of *Clematis montana*, usually called *C. montana grandiflora*, as its beauty in the early part of the year, before any of the other kinds expand, is unsurpassed by that of any other hardy or tender climber. No one looks upon the clematis as a hedging plant, yet any of the more showy kinds would make magnificent hedges if allowed to ramble over a raised surface, in the same way as we have recommended the white everlasting pea to be grown. Whoever gives clematises a fair trial will not be disappointed.

LATE TULIPS.—Plain people, who do not intend to sacrifice their days and nights, and more money than they can afford, to the growing of late tulips, ought nevertheless to have them, because of their gorgeous beauty. It is easy enough. Good mixtures are quoted in catalogues at half-a-guinea a hundred. These will produce flowers as good for garden decoration as bulbs of Charles Williams, which are now selling at twenty-one pounds each. If you want names, precise markings, characters suitable for pedantic discussions, you must become a tulip grower, which in many cases means that you must rob your family, enjoy the headache, and become a slave to roots that would not nourish you a single hour if you and your tulips were together cast upon a desert island. But to have all their splendour at a trifling cost, prepare a four-foot bed, or even a narrow border—perhaps a border with some shrubs in the rear is the proper place for this business. Sandy loam, well manured, is all you want. In this plant your cheap mixtures, six inches apart, six inches deep, and leave them alone four years. Then take them up, separate, replant, give away the surplus, and go on as before. You will be a tulip-grower minus the madness: who can object to that?

DAFFODILS.—All the varieties of Polyanthus Narciss make beautiful subjects for pot culture. They require the same soil and treatment as hyacinths, and the number of bulbs put in a pot must be regulated by their size. A fine hurb of Grand Monarque will require a six-inch pot. The following are the most distinct and noble: *Bazelman Major*, *Gloriosa*, *Grand Monarque*, *Grand Prince*, *Soleil d'Or*, *States-General*, *Double Roman*, and *Paper White*. For open borders the following are beautiful: *Incomparable*, *Orange Phoenix*, *White Dutch*, *Van Sion*, *Common Daffodil*. The best way to deal with them is to plant them in clumps of half-a-dozen to a dozen bulbs in shady borders, and not to disturb them for the next seven years at least. The gardeners are so fond of digging borders, however, that you may think yourself fortunate if they are not all chopped into mince-meat within a year of being planted. It would do incalculable good if some lover of flowers would chop one of these border-diggers into mince-meat, as a caution to the rest!

THE ROMAN HYACINTH is a small white bulb, which produces small spikes of snow-white flowers, or small spikes of blue flowers. They are grown in vast quantities for Covent Garden Market, and may always be found in wedding bouquets during winter and spring. As trade articles they are scarce; the market growers usually monopolize the supplies. Pot them as soon as they can be obtained, plunge them with two inches of cocoa-nut fibre over their crowns, and, as soon as the green spikes peep through the material, take them out and put them in frames and green-houses. If a very early bloom is wanted, pot in August, and, when well rooted, put them in gentle heat, and they will bloom in November. As a border bulb, Roman hyacinths are most useful, and the way to treat them is to plant four inches deep, and leave them undisturbed for several years.

CROCUSES suffer much by being kept out of the ground till late in the season, and with being lifted before the leaves have died down. Plant them three inches deep in clumps or lines, and leave them untouched three years, then divide, manure the ground, and plant again. Nothing to surpass common white, yellow, and blue for the open ground, but the named varieties should be used for pots. Put five bulbs in a five or six-inch pot, using rich sandy soil, and treat the same as advised for hyacinths. If no room for them in the greenhouse, they can be flowered well in a frame. The following are splendid varieties: *La Majestueuse*, *Sir Walter Scott*, *David Rizzio*, *Mont Blanc*, *Cloth-of-Gold*, *No Plus Ultra*, and *Queen Victoria*. Any of these may be had in bulbs as large as walnuts—and the larger the better—at from 3s. to 6s. per hundred. The price of the common kinds is 1s. 6d. to 2s. 6d. per hundred.

Fruit Garden and Orchard House.

HARDY FRUIT to be gathered as soon as ripe, which may be known by the colour of the pips, and by the stalk parting readily from the tree. Gather with great care, and keep apart from the best all that fall in the process. Gather only during dry weather, and store at once; there is not the least need for the "sweating" process usually adopted. The fruit store should be in a dark place, capable of being freely ventilated, yet generally admitting but a trifling current of atmosphere; and it should be cool, and yet safe from frost.

WALL TREES only need such care as may be necessary to assist in the ripening of the wood. Where spray-like growth and rank shoots overlap and shade wood selected for bearing, remove it or cut it into reasonable bounds, for the wood laid in needs now all the sun it can get, and it is sure not to get too much. Train in regularly, and by all means avoid overcrowding.

Greenhouse and Conservatory.

FUCHSIAS that have gone out of bloom may be cut back to neat shapes, and put in bottom-heat till they break freely; thus treated they will flower finely during November and December in the greenhouse or conservatory, with the help of a little warmth.

Stove and Orchid House.

ORCHIDS ripening off must have as much air as possible, but with caution, as a chill at such a time is more likely to cause spore in the next growth than when the plants are full of vigour. In the same way the withholding of water must be by degrees, and not suddenly, and the cultivator must bear in mind that many orchids when in their native sites are never dry, except perhaps for an hour or two at midday; hence the reduction of atmospheric moisture must be carried only to a certain point.

WINTER FLOWERS.—Many subjects in the stove may be turned to account to supply winter flowers, if attention be paid to them in time,

Indeed, we look to the stove for the decoration of the dinner table, and for occasional embellishments of the conservatory, until the bulbs, cinerarias, primulas, and cyclamens come in once more.

ORCHIDS THAT MAY BE IN BLOOM IN SEPTEMBER.—*Aerides suavisimum*; *Angreum caudatum*; *Barkeria melanocaulon*, *Lindleyana*; *Bletia campanulata*; *Bolophyllum saltatorium*; *Brassavola acanthis*; *Cattleya bicolor*, *candida*, *granulosa*, *Harrisonia*, *Harrisonia violacea*, *Loddigesii*, *marginata*, *pumila*, *violacea*; *Cypripedium Farrisianum*; *Dendrobium Gibsoni*, *Heyneanum*, *sanguinolentum*; *Dendrochilum glumaceum*; *Epidendrum phoenicium*, *vitellinum majus*; *Huntleya Wailiesii*; *Laelia elegans Dayii*, *furfuracea*, *Perrini*; *Miltonia candida*, *Clowesii major*, *Morelli*, *Morelli atrorubens*, *Regnellii*; *Oncidium bicolor*, *crispum*; *Peristeria elata*, *guttata*; *Phalænopsis amabilis*; *Promenæa Rollinsonii*, *stapeloidea*; *Stanhopea aurea*, *insignis*, *Martiana*, *oculata*, *tigrina*, *tigrina lutescens*; *Trichopilia picta*; *Vanda Batemanni*, *Lovii*.

Forcing Pit.

STRAWBERRIES to be forced should now have well-formed plump crowns. If the crowns are thin and weak, put them under glass, and assist with weak liquid manure.

PINES.—Plants swelling their fruit will need a little clear liquid manure: nothing better than soot-water. Guard against any of the young plants fruiting prematurely; to prevent it, keep them liberally watered, and in a warm moist atmosphere.

VINES that have ripened their fruit to be kept well aired, cool, and dry.

HYACINTHS IN POTS.—One of the first steps to achieve success with these splendid subjects is to secure suitable bulbs. Some of the samples with which first prizes are taken at great meetings are so large that it is with difficulty they can be potted into 48-sized pots. Of course such bulbs fetch a long price, and very few private growers would purchase them. Such bulbs do not always, however, make a proper return for their extravagant cost, for instead of throwing up one huge spike, which is exactly what we want of them, they sometimes produce half a dozen medium spikes, and are then magnificent for decorative purposes, though not adapted for competitive exhibition. In selecting these extra large bulbs it is always preferable to take those with a distinct central neatly-finished point (or crown) to those that are rough or showing the slightest tendency to divide vertically. When the whole bulb has but one set of scales, and these come to a nice finish at the growing point, they usually produce only one spike, and of course that is a monster, and counts for one to show. But very fine exhibition spikes may be grown without extra-sized bulbs. Some good sorts never make large bulbs, and some never make handsome bulbs. We advise the grower who does not mind paying a little extra to give the dealer notice of his desire for picked samples for exhibition, and at some advance on the average rate. Grand specimens may be obtained, such as are never parted with at catalogue prices. This fact is not generally known, and exhibitors do not care to have it known too widely, because of the monopoly they enjoy of these "first selected" samples on the arrival of the bulbs from Holland. In selecting bulbs, size and shape are not all-important. Get large bulbs if you can; get them with one distinct and nicely-finished crown, but above all things be sure of this—that they are heavy. We weighed a lot of Koh-i-noor and Solfaterre bulbs last year, and made notes of them when in bloom. The heaviest gave the finest spikes and the richest colours. All the light ones were poor spikes, and some of them were quite washy in colour. We never knew Milton or Howard to come fine from any but heavy bulbs, and, indeed, the rule holds good throughout, but applies especially to high-priced sorts, because these the growers do their utmost to increase, and of necessity hard propagating results in the production of samples not quite up to the mark, for the prices they realize tempt the growers to send as many into the market as look fit for the purpose. Size and shape are not unimportant characters, but weight is the final and decisive test. As to the growing of them, the highest prizes in spirited competition, have been taken with bulbs potted as late as Christmas. Late potting, therefore, is not of necessity fatal to success. One thing is certain, if the bulbs are to be potted late, they must be preserved from contact with the atmosphere. Put them away in dry chaff, or any such preservative: the husky stuff they are packed in by the Dutch keeps them well; but whenever we have had to pack a large lot away in a fresh store we have used grass-seeds, which, of course, were just as good, after they had served this purpose, as before. Still, though keeping them out of the ground till the end of the year does not of necessity ruin them, we prefer to plant early, reserving a few to plant late, so as to secure a succession of flowers. Private growers are not generally aware that the proper stuff to use in potting hyacinths for exhibition is a mixture consisting of one-half fat dung and the other half good turfy loam, with a large admixture of sharp sand. The sweepings or scrapings of a much-frequented gravel road answer admirably to incorporate with the mixture to render it porous. To secure abundant root-room, use only one crock over the hole in the pot; then fill in and press moderately firm; then press the bulb down in the centre till it is more than half buried; then fill in round it with fat dung alone. If the soil is in a moderately moist condition, the potting may be performed with great rapidity, and the bulbs will hold well in their places; but if too wet or too dry when the potting takes place, they will be apt to tilt on one side as soon as the first roots push, and this will very much interfere with their beauty when in bloom, as the stems will be bent near the base. As an additional precaution against tilting over, do not pot them too firm—that is to say, do not press the bulb so hard that it will be bedded on a pavement when in its place, as the first roots, being unable to penetrate the hard soil, will lift the bulb up, and, once out of position, it can never be nicely put right again. All other details of cultivation are the same as have been described in this and other works again and again. The pots containing the bulbs should be packed close together in a well drained bed, and have one good watering. If small pots are plentiful, place one inverted over every bulb, to prevent the plunging material from touching the bulbs, and to preserve around each a film of dry air. This practice prevents mildew, and tends also to retard growth—two signal advantages. They should then be covered six inches deep with coal-ashes, or any other suitable material, the most clean and suitable being cocoa-nut fibre waste. They should never remain in this position beyond the 15th of February, but in mild winters will have to be removed at least a month earlier. Under any circumstances, they may be allowed to push three inches before being taken out, but after that it would harm them to remain. Place them for a week on the floor of a cool house to become green; then put them in a gentle heat, and according to the time when wanted in bloom force them fast or slow, always taking care to keep a few back in full daylight in a cool house, and

from frost, to furnish the latest display. Those expected to give extra fine spikes should be assisted by a top-dressing of sheep's dung from the time when the spike begins to rise freely. If there is no room to put this dressing on, remove a little of the stuff first used to fill up the pots with round the bulb, so as to introduce half an inch depth of the fresh dressing. Manure water we strongly object to, chiefly because of its liability to mis-use. When we have to trust much of our work to others, the more simple the routine the better, and by using top-dressings and pure soft water the plants are much more safe than when liquid manure is allowed; for one dose of it, if it is a little too strong, will ruin the hopes and labours of a season.

EARLY TULIPS.—This is a valuable section of bulbs for the decoration of the garden. Fortunately they are all good, so it scarcely matters what sorts people purchase. Early tulips may be flowered in beds and borders in time to be removed to make room for the ordinary summer hedges, but a better way is to plant them in such a manner that they may remain in the ground two or three years, the geraniums, verbenas, &c., &c., being planted between the rows of tulips, so as to avoid the necessity of disturbing them. What splendid things they are in pots is well known, such sorts as *Van Thol*, *Pottebakker*, *Rex Rubrorum*, *Trionon*, *Yellow Prince*, and *Froserpine* being grown in thousands for Covent Garden Market. And as telling secrets seems to be our province, this time we will tell you how the best market-growers manage them. You will observe that a market specimen of Van Thol consists of three bulbs in a five or six-inch pot, all the flowers in exactly the same degree of expansion, matching so well that a person uninitiated is sorely puzzled to know how the thing is done. In private greenhouses we see pots of tulips with the flowers in different stages of advance, some full out, others half out, and so on. The bulbs in a pot refusing to move precisely at the same pace. This would never do for market-growers, and so they accomplish by stratagem what skill is quite unequal to. They plant all their bulbs in beds of turfy loam in pits, greenhouses, and the open ground. When preparing to send to market they take up such as have the flowers half expanded—that is, when the flower is about the shape and size of a walnut, and not at all expanded to a cup. They pot these three in a pot to match exactly, and then go to market with them and astonish mankind with apparent evidence that the bulbs obey their bidding and flower to the very hour they are required.

AN INVALUABLE RECIPE.—If you have a screw rusted into wood, or a nut or bolt that will not readily turn, pour on a little kerosene and let it remain. In a little while it will penetrate the interstices, so that the screw may be easily started.—*Builder*.

THE GARDENER'S CONSCIENCE MONEY.—The Westmoreland Gardeners' Lodge, No. 142 (Kendal), held a meeting some time since for rather a novel purpose. Some 30 years ago, when the lodge did not muster so numerously, and was not so rich as at present, one of its members was entrusted with more than £30, for the purpose of purchasing regalia. The man was young and poor, the temptation strong, and neither man nor money was again heard of until lately. One day a person of respectable exterior and gentlemanly deportment, a stranger, waited upon the secretary and asked him to convene a special general meeting of the lodge. This was done, curiosity became excited, and a numerous attended gathering was the result. It then transpired that the stranger of respectable exterior and gentlemanly deportment was the missing "gardener" of 33 years of age, who had come all the way from America to repay in person, and with ample interest, the money which he had appropriated in his poorer days.

Correspondence.

FOXLEY'S BEADED BRICKS.—I am about to build a garden wall with east and south-east aspects, good therefore for peaches and nectarines. I meant to build it with the patent beaded bricks, but have been told that they have not been found to answer in and about London where they have been tried for several years, as the wood of peaches and nectarines does not ripen well on them. Is that the case? The bricks I get here stand the frost well, as a wall I have, with west aspect, built with them late last Autumn is not in the least damaged. A very good gardener near here has tried them three or four years and likes them, and does not find they hinder the wood from ripening. I know last winter destroyed the beads of numbers of bricks in the West of England, but that must have been a local defect of clay or making. The plan on which I built my wall last year was to have panels 6 or 7 feet wide of 4½ inch work, between 14 inch piers, 27 inches wide; the piers had two beaded bricks in every other row; and I planted a pear-tree on the quince stock against each. I should think that the pear-trees trained as semi-cylinders would help (even in winter) to break the sweep of the wind along the wall. The panels do well for pears, plums, &c., roots pruned or lifted biennially. I should be obliged by an answer in your Magazine. W. L.

[This is the first we have heard of Foxley's bricks being unsuited to the ripening of the wood, or liable to injury by frost. Can any of our readers throw light upon the subject?]

WELLS'S PORTABLE GROUND VINERIES.—I see in your Magazine of August 17th, one of your correspondents asks for information respecting Wells's Patent Portable Ground Vineries. Will you kindly inform him the Vineries at Southend are open for the inspection of horticulturists and amateurs daily, where some twenty vineries, with an average crop of grapes, may be seen; and, on any Monday, the Patentee will be most happy to afford the fullest information? CHAS. T. WELLS.

Pleasant Row, Southend.

EXPERIMENTAL CULTURE OF VARIEGATED ZONAL PELARGONIUMS.—A little error which occurs in your report of my experimental culture of zonal pelargoniums alters the conclusions to be drawn from it, which I should consequently like you, in an early number of the GARDENER'S MAGAZINE, to set right—viz., in No. 37 for "Seed Parent, Madame Vaucher," substitute "United Italy." I should also like to remark upon one or two points connected with the subject, and my experiment, so far as it has proceeded. In the first place, I wish especially to observe that the experiment was undertaken, not with the idea of obtaining

any really good or valuable addition to the already splendid army of tricolors, although, of course, I can have no objection to the appearance in my collection of seedlings of any number of varieties superior to such as are already in cultivation. The sole object of my endeavour has been to glean, if possible, some clue to the laws that govern the transmission of resemblances from the parents to their offspring, not only as regards colour, form of foliage, and constitution, but also as regards colour and form of flower.

With this object, as your readers have already learnt from your Geranium paper, No. XLIV., I crossed the most opposite varieties, both as regards habit of growth and form and colour of flower, as well as colour of foliage: for instance, *Lady Cullum* and *Stella Nosegays* with *Mrs. Pollock* and *United Italy*, &c., &c.

Your article, Mr. Editor, gives the result upon the foliage and constitution as appears in their early stage; for their complete development and for the result upon the flowers we must wait until next spring. But, so far as can be judged up to the present, my experiment tends to confirm the opinion that the colour, say of a tricolor crossed with a green zonal, is transmitted to a larger proportion of the offspring by the pollen of the tricolor being employed, rather than by making the tricolor the seed-parent, and the green zonal the pollen-parent. The constitution and form of foliage seems to me in the offspring to resemble in a large proportion the more vigorous of the two parents; and as constitution and form of foliage furnish the foundation of the future variety, it is desirable and advisable to order the system of breeding with a view to secure a vigorous race. This, apparently, can be most certainly secured by employing a robust constitution plant, with a perfectly formed foliage, for the seed-parent, and the pollen of any coloured foliage it may be desirable to transmit, or which you may consider calculated to produce a desired result. The Editor has put the case clearly where he says, "Select for the mother plant one possessing strength and form, and for the sire one possessing splendour of colour."

This brings us to the question, how far we can introduce or blend the colours of the foliage or flowers so as to obtain new and pleasing varieties, and the best method to adopt to accomplish any particular end we may have in view. Well, we are admonished to study not only how a plant grows, but how it dies. From observation of fading leaves, and carefully watching the breaking of my seedlings, I am convinced that the colours of the tricolors depend more, if not entirely, upon a change in the ground colour of the leaf than upon any mixing of colours in the zone. Mr. Grievess, if I understood his statement aright, succeeded in raising *Mrs. Pollock* by working upon the assumption that he should obtain what he did by blending brown and yellow in the zone; but I believe he has since acknowledged that his theory could not hold good, red being a primitive and not a compound colour, and therefore not producible by blending brown and yellow. In the fading of the leaf of all our dark zonals, when yellow takes the place of the green the zone becomes red. Madame Vaucher constantly shows this. If the leaf fades whitish, the zone becomes pink or carmine. The order of procedure in what, for the sake of a term, we may characterize as *transcoloration* is, in fact, precisely the same in the fading leaf as occurs in the seedling in process of development. Where they break in splashes, as they mostly do at first, for instance, the leaf will be green, with a dark zone, excepting where splashed with yellow or white; and where the yellow splash passes across the zone, it will be red; but where a white splash passes, the zone will be pink. This, I think, clearly indicates that to obtain either a golden or silver tricolor, the method to be adopted is to employ, for the first, the pollen of a yellow or golden-leaved variety; and, for the second, to select as near as possible a white, and to put the pollen of each upon as densely a zoned one as possible. One of my seedlings promises to be all but white, and another is decidedly a brighter yellow than anything else of the kind I have yet seen. If these live to flower, I shall try their pollen as above suggested, with a view to obtain their splendid colours in plants of good constitution.

Next, as to blending. Can we blend the colours so as to obtain any decided variation from what we already possess? It seems to me that the yellow with brown zones, such as are classed as bronze zonals, have originated from crossing the yellow upon the silver tricolors, or the reverse. Amongst my seedlings is one of that class, the result of a cross in which *Cloth-of-Gold* was the pollen-parent, and the *Countess of Warwick* the seed-parent.

We are all as yet but experimentalists in the art of breeding versicolored-foliaged geraniums; and who is to say that some one may not succeed in adding a streak of blue to the brilliant colours of *Mrs. Pollock*, or in obtaining some new admixture or combination which may take the floral world by surprise as completely as did the advent of the famous first of the series, for which we are indebted to Mr. Grievess? Let us labour systematically, and keep careful records of our work, and "knowledge will be widened by the progress of the suns." JOHN DENNY.

GROUND VINERIES.—I see you ask the opinion of grape-growers respecting the use of ground vinerias as applicable to the case of a correspondent who makes inquiries. Having seen them many times in use, and reported on the success attending their adoption by Mr. Rivers and other practitioners, I am in a position to discuss this subject with your correspondent without prejudice. My advice would be to let the vinery your correspondent now has, and which he admits his gardener manages so skilfully, remain as it is, and instead of purchasing twenty portable vinerias, to build a new greenhouse. My reason for giving this advice is, that I feel sure "Viteæ" will be disappointed with the result of ground vinerias after being so long accustomed to a good crop of large, well-coloured, and well-flavoured bunches. Not but good grapes can be grown in ground vinerias, and such too as would not disgrace any gentleman's table. But there is a vast difference between a beginner in grape culture and one who has for a long while enjoyed the luxury of grapes grown in a good house. A stranger to both systems would probably be very well satisfied with the result of portable vinerias, but I doubt if in this case it would be wise to expend more than £60 upon ground vinerias, when that sum would furnish a new house suitable to the wants of the place. It appears to me that this would be an unwise step, which to a certain extent would end in disappointment. But it must be understood that these remarks only apply to the case under notice, and not to ground vinerias generally. They are useful structures in small places where only a few grapes are required, and they are capable of producing them at a cheap rate and in very good condition. J. C. CLARKE.

SURPLUS PLANTS AND CUTTINGS FOR THE POOR.—Relative to the above subject, do the authorities connected with the public parks and gardens

intend to continue the practice lately adopted of giving away, instead of destroying, any surplus plants or cuttings. It is a great boon to the poor, and no doubt is a great means of diffusing a love of plants among our poorer classes, by placing within their reach the cultivation of a more valuable description of plants than they could possibly purchase.

WASTE NOT, WANT NOT.

[We understand that it is the intention of the Office of Public Works to sanction the free distribution of surplus plants from the London parks. We must confess we do not think so highly of the arrangement as our correspondent, for, as a rule, it requires better appliances and more skill than the poor usually possess to keep the plants through the winter. The very class intended to be benefited may indeed, through the temptation of a gift of this sort, find plant growing in dwelling rooms to be a wearisome and vexatious task. If any plan could be devised for a liberal gratuitous diffusion of nice young plants in spring, such as fuchsias, geraniums, heliotropes, stocks, balsams, herbaceous lobelias, &c., we would gladly assist and encourage, knowing that much delight would follow; but we never expected any good to result from the distribution of bedding plants in autumn. If any of our readers can furnish evidence of benefit in that way, we shall gladly give it publicity].

Replies to Queries.

Strawberry Plantations.—I planted a good breadth with strawberries last spring; I now find, according to the Magazine, that I have planted them too thick by half. I have a piece which I intend to plant this autumn. Would you advise taking every other plant of those planted last spring, or would you prefer this year's runners? C. J. H.

[We should prefer to make a new plantation by taking every alternate plant from the piece made last spring. If transplanted with care in the first showery weather that occurs, they will not feel the move at all. As to the runners, we should destroy them unless requiring them to extend operations. Next year, however, it would be advisable to make plants of a certain number of the first runners with a view to a new plantation. It is a good plan to plant a row or two of young plants from runners every year.]

Creeping Innocence.—Your *nom de plume* is tolerably appropriate to your query; the name of the plant is *Linaria cymbalaria*, the "ivy-leaved toad-flax" of the village botanist, and now the "creeping innocence" of a resident of Kensington. By the way, does innocence ever creep? does it not advance boldly, even in the face of danger, knowing neither suspicion nor fear?

J. B.—Your consignment was examined on the day it arrived, but nothing could be made of it. Nine-tenths of all the flowers that are sent for opinion are past judgment ere they reach us. It is just the same in other quarters, as may be learnt from replies to correspondents. Yet, strange to say, flowers may be sent hundreds of miles without any sensible deterioration of their freshness and beauty.

Walter S.—Your pelargonium, packed in cotton-wool, in a card-board box, was quite dried up when it came to hand. The dry petals are of good form, broad and thick, and a fine blackish maroon colour overlaid with crimson veins. No doubt you have something good, but we cannot commit ourselves to an opinion on this sample. Should you ever send again, let a note accompany the parcel, and pack the flowers according to the advice given at page 285 in the No. published June 29, 1867.

Trevelyan.—Apparently British Queen, but not easy to determine from one pod, and no particulars as to height, &c. Isolated reports on weather are of little practical value. It did not occur to us that there was any particular interest in your communication; if we come across it again, it shall have consideration.

Preserved Peaches.—Sibley.—We have several times tried the preserved peaches sold in London in sealed tin cans. Whether the Americans spoil them in the process of preserving, or whether the voyage spoils them afterwards, we do not know, but really we never met with a single fruit of this sort that was fit for any useful purpose. They look like balls of soap, and taste like sour bread dipped in dirty water.

Literature.

The Choral Cyclopædia, a collection of Hymns and Moral Songs, with Music—Watt's Psalms and Hymns, abridged for vocal use and adapted to Music. By JAMES BRABHAM, F. Pitman, Paternoster Row. These are cheap and good, and admirably adapted for promoting harmony in the family. All our music-loving readers, and especially those who have children, should look after these works; for possibly there is nothing else of the kind to be obtained equally good at so low a rate. Each number contains forty pages of music, well printed, for sixpence. Mr. Brabham's arrangements are excellent.

Country Life, a Journal of Rural Pursuits and Recreation.—This work is in some respects a rival of the GARDENER'S MAGAZINE; but we shall not follow the usual paltry course of ignoring it, for it is respectable in purpose, tone, and appearance, and instead of wishing it out of the way, we embrace this the first opportunity since its appearance of directing the attention of our readers to it as likely, in many instances, to meet their wants. It is projected with a view of promoting the love of rural pursuits of all kinds, and at present it appears to be strongest in the gardening and poultry departments. As there is nothing like leather, we cannot hesitate to say that for horticultural information there is nothing like the GARDENER'S MAGAZINE. But in "Country Life" Mr. Richard Dean does his best, and does it well, to make the garden a book, and make a good book on the garden. The poultry department is very promising, and as the only respectable journal devoted to poultry subjects, namely *The Field*, is higher priced than suits some thousands of persons interested in poultry, here is a good opportunity presented them for supporting a work immediately interested in and devoted to their welfare. As for other matters, there are capital papers on angling, wayside botany, and an article entitled "Our English Homes," will show that in the midst of stern practical matters some thought is spared for æsthetics. We were ourselves contemplating the production of a work of this kind, but with so promising a work as "Country Life" before us, we abandon the idea, and wish the new venture abundant success, freely forgiving its promoters for unintentionally forestalling us with spirit and with speed.

THE COLD PIT AS AN AID TO THE FLOWER-GARDENER.

During recent years some sagacious gardeners have been employing extensively what is called the "turf pit," and when well made and judiciously managed—both very simple affairs—nothing can be more useful, nothing more excellent for the garden. The pits are simply made of sods of turf cut rather thin. Some good gardeners, indeed, skin the turf of their pasture, and make the walls of their little pits with it, using merely the turf, a couple or three inches thick; and when it has acted as a wall for twelve months or more, they take it down, it being then nicely decomposed and aerated—in fact, in the best possible condition for potting. Now, whether this be the system adopted or not, it will be seen at a glance that building pits of this kind is a very cheap process. All that we want is some kind of turf, and then to have it cut neatly and made into little walls by a handy labourer. The sods may be cut from eight to ten inches wide, more or less, according to the height we require the pit. Generally it will be well to follow the plan of a little brick pit, or even of a frame, so far as the height of the sides is concerned. Usually a rough plate of wood is placed on the top of the little sod-walls, and on these the lights are placed. But a better way than that is to use nothing whatever except the wall of turf, leave the top sod with its level green side upwards, and on that rest cheap iron lights. Of course, wooden ones would be apt to rot quickly in such a case. The best possible arrangement, then, is to have little cheap iron lights, such as are used abundantly about Paris, say about four and a half feet wide. These are not expensive nor very heavy, and the sooner they are turned out in quantity by some of our horticultural builders the better. However, any kind of light may be adapted to the system. We advise the iron light, convinced that these turf pits are about as useful things as we can have in the garden, and likely to be always appreciated. Some use tarpaulin lights and boards and other opaque substances to cover such things; but we have no faith in such contrivances, and glass is cheap enough now to do away with the necessity of using opaque coverings in our very dull winters. The width that we should choose for such frames, if we were going to order lights for them, would be from four to five feet—say five feet as a rule. But of course, if we have any old lights, and wish to utilize them in this way, we must make the pits precisely to suit them. The appearance of neat turf pits is in no degree more objectionable than stone ones. Their proper place is an out-of-the-way nook, which we generally call the melon yard, or some equivalent to that department. In all cases they should be away from the ornamental parts of a garden, as all pits and frames generally are. They should have a free open position. Some people have a weakness for putting such things in dusty corners, under trees, &c. A well-drained position is of course best; and if we can place them on one of those beds of coal-ashes which often occur about a country place, so much the better. In most cases it would be better to have the bottom lowered a little, especially if the soil beneath were of a dry nature. In some pits beds of fine earth can be placed, on which to place cuttings in quantities. In others they will prove equally useful for storing plants in pots. In addition to bedding plants, pot roses, strawberries, and lots of other things, will be thankful for temporary shelter therein.

As for what may be grown and preserved in them with safety among bedding plants, there need be little doubt. The best of all places for the *calceolaria* is in such a pit. Cuttings put in in October and November will do finely indeed; it is the best and most successful of all ways of growing these. Then all half-hardy things may be tried in them with confidence, from cuttings and little divisions of our edging plants to the tall herbaceous lobelias, which are so very fine when in flower, but a little too tender to stand the open air in most parts of our climate. Perfectly hardy stuff, like the variegated arabis, &c., which it may sometimes be desirable to increase largely in the autumn, will succeed well, and be ready for turning out finely-developed plants for the next bedding season; while as for Neapolitan violets, and young, scarce, and delicate herbaceous plants, variegated plants, &c., which we much wish to increase, it is the very place for them. If verbenas were struck very early in the season, and, once rooted, allowed four or five weeks in the free open air before it became necessary to house them, they would thrive admirably in these pits. In consequence of gardeners generally striking verbenas too late, they are obliged to keep them in warmer or drier structures, or they would be sure to go off. The *Gazania* does capitally put in as cuttings in these pits; so does the *Nierembergia*. By the way, there is a fine new *Nierembergia* (*frutescens*), which will be found a capital bedding plant, and its best winter home will be in one of those pits; and so of all but the tenderest bedding plants.

Every year we have a greater variety of subjects introduced to our flower gardens; and, as most of them are of a half-hardy character, or even if hardy, such as will enjoy a little protection in winter when in a young state, the knowledge of the advantages of these cheap pits cannot be too widely diffused.—*The Field*.

CATALOGUES.

PAUL AND SON, "OLD" NURSERIES, CHESHUNT, HERTS.—*Descriptive Fruit Catalogue*. This is well adapted for persons who care only for good serviceable varieties, and who have no particular anxiety about novelties or curiosities. The lists are comparatively brief, but sound and good, and with sufficient description to be useful to the merest novice.

SUTTON AND SONS, READING.—*Catalogue of Bulbous Flower Roots, &c.* This, in addition to the usual well-arranged and well-selected lists of bulbs, contains also lists of British and exotic ferns, fruit trees, and flower seeds for autumn sowing. The name of the firm is sufficient guarantee of the genuineness of the catalogue and the stuff it represents.

JAMES VEITCH AND SONS, KING'S ROAD, CHELSEA.—*Descriptive Fruit Catalogue*, 1866-1867. Copious, well-arranged, with capital descriptive notes and suggestions to aid in the selection of varieties for various purposes.

B. S. WILLIAMS, UPPER HOLLOWAY, LONDON, N.—*General Bulb Catalogue and Catalogue of Fruit Trees*, 1867. One of the neatest and most useful trade publications of the season. In the fruit list there is a good selection of varieties of grapes. In the introduction to the list of hyacinths, it is remarked that "the new introductions are necessarily to be procured only at such a rate as to place them beyond the reach of many cultivators; but in most instances these novelties possess the novelty of name alone, for it has been proved that the finest shades of colour and richness of hue are still to be found in the old or parent kinds." This statement will not deter lovers of novelties from buying bulbs at a guinea or so each, but it must of necessity comfort those who cannot afford so much.

The Gardener's Magazine.

SATURDAY, SEPTEMBER 14, 1867.

TO OBTAIN WATER QUICKLY AND CHEAPLY is one of the most important matters in the economy of country life. The townsman may fairly consider the good and abundant water supply with which as a rule he is favoured as a compensation for many of the evils of town life, and as a grand set-off against many of the troubles incidental to life in the country. During our recent visit to the Manchester exhibition we made acquaintance with an invention which we are desirous of directing attention to, as likely to prove incalculably beneficial in cases where a quick and cheap supply of water is a matter of any moment. We will briefly relate what we saw. Two men commenced boring the ground in the Botanic Garden at Old Trafford, with a pointed boring tube two inches in diameter, and in the course of about half an hour had driven it a depth of five feet. They then commenced to gauge the interior of the tube with a plumb-line; and finding that the plumb came up wet, they at once attached to the upper end of the tube a pump, into which water was poured to wet the sucker, and quite fill the tube. In the course of a few minutes there was a constant stream of pure water drawn from the soil beneath the grass turf, without any well, with an amount of expense and labour of the most trifling description, and to be counted in pence rather than pounds or shillings. A more simple, expeditious, or effectual method of tapping the soil is, we suppose, neither to be found nor desired, and we can well believe that in many instances such a tapping would be preferable to well sinking, because surface drainage into the source of supply is impossible. A well of this sort cannot be poisoned by the percolation into it of the filth from drains.

In case this brief description is not fully intelligible, it may be well to add that the boring rod or tube is made in the fashion of a handspike, and the driving end is brought to a point to facilitate its descent. Where the point of the tube terminates, the tube is suddenly thickened, and beyond this point it contracts to a regular diameter, which is less than that of the thickened base of the point. About one foot length of the tube nearest the base is pierced with small holes to admit the water from the soil to the interior; and the object of thickening the tube immediately below these holes is to cause the formation of a hole slightly larger than the tube, and thus prevent the orifices being choked up. No doubt they do get choked in time, but that only necessitates drawing the tube and driving again in another spot close by. We were assured that the tube could be driven twenty or thirty feet if surface water were not obtainable. What we saw was the instantaneous abstraction of water in a plentiful stream from a depth of five feet, and we consider the matter far too important to be withheld from our readers, or presented to them in other than a prominent manner. The invention bears the name of the "The New Patent American Tube Well." The agent for it is Mr. Alfred Giles, who can be heard of at Norton's Machinery Office, Blackfriars Street, Manchester.

Dr. J. D. Hooker, the learned Director of the Royal Gardens at Kew, is to be President of the British Association in 1868, when the general meeting of members will be held at Norwich.

VEGETABLE HAIR.—Californian papers state that there is now dug out of the mountains of the Sierra Nevada range a better material for beds than has been hitherto available in the markets of the world. It is the soap-root, which grows in unlimited quantities in that region. It is a bulbous root, enveloped in a very tough and supple fibre, resembling somewhat the husk of cocoa-nut in colour and appearance, but nearly as tough as whalebone. The roots are dug chiefly by Chinamen, bound in bundles of 100lb. each and brought on poles to the factory. The first work is to put the roots through a picker similar to a thrashing-machine, which is run by horse-power. This separates the fibre into a bair of eight or ten inches long, which is placed in a large vat or steamer till it becomes flexible, and is free from all gummy or glutinous matter. It is then dried on flats in the sun, put through another fine picker turned by a Chinaman, then taken and twisted into ropes at a common rope-walk, then steamed again, which sets the curl. The ropes are then bound in bales, and are ready for the market. The natural colour is brown, but it is often coloured black, and an expert would find it hard to tell it from curled hair.

No. 124, NEW SERIES.—VOL. X.

HALF-A-YEAR'S RAIN.—The variation in the quantity of rain in different parts of the kingdom is shown in the returns just published by the Registrar-General. In the first half of the year 1867, 20.5 inches of rain fell at Bristol, 20.1 at Glasgow, 18.2 at Sheffield, 15.5 at Birmingham, 15.4 at Salford, 15.1 at Manchester, 14 at Edinburgh, 13.1 at Dublin, 13 at Leeds, 12.6 at London, 10.1 at Liverpool, and only 8 at Newcastle.

AN INTERESTING EXAMPLE OF SPECIES-MAKING is presented in the September number of the *Journal of Botany*. Mr. Andrew Murray finds a variety of *Abies alba* with short cones, rounded scales, and triangular bracts, and he proceeds to name it *Abies arctica*. There are not greater differences between the typical *A. alba* and this variety of it than may be found amongst plants of the same species of coniferous trees in seed-beds in every great nursery in the country. Species-making is possibly amusing; but how strange that botanists so rarely find amusement in the application to useful purposes of what they know of the affinities, relations, and habitudes of plants!

GRASSHOPPERS IN AMERICA.—The ravages of these little pests seem to have begun in earnest. The hemp crop of the county has been almost entirely destroyed. A few crops may escape them. One day suffices for them to clean off a hemp field as bare as before the sowing. The blue grass is in many places destroyed, and has suffered much wherever they have gone. Timothy and clover have also been very greatly damaged. The oat crop, it is thought, will be utterly ruined, as they prefer that to wheat, which they have so far only slightly damaged. The corn is not exempt, but has been injured less than any other crop except wheat. The gardens have suffered terribly, nearly all early vegetables having been eaten up by them. They swept a garden bare in a few hours. A lady informs us that in the morning she had as fine a garden as she ever saw, and in the evening scarcely a vestige of it was left. It is consoling to know that the weeds also suffered.

SEWAGE-GROWN GRASS.—The Rivers Commissioners, in their third report, discuss the assertion which is sometimes made, that sewage-grown grass is unwholesome, and will not make good hay. The commissioners consider it proved that the grass is not only wholesome, but that cows fed upon it give richer milk, from which first-class butter may be made. The chemist proves by careful analysis that both milk and butter are better than samples produced from the same land in its ordinary state of meadow. Hay made from sewage-grown grass is also sweet and nutritious if properly got, but there is great difficulty in fully drying it during ordinary seasons. When a limited quantity of sewage or other water containing manure soaks into a fertile soil, the first effect is to displace part of the water already contained in the soil, occupying its place in the interstices, whence the organic matter it contains is held in temporary union with the active soil, to be afterwards absorbed by the roots of plants or decomposed by the air, so that in a short time, varying according to the activity of vegetation and of decomposition, no impurity whatever remains. If then the sewage which has soaked into the soil is not displaced by other water until a sufficient time for it to be purified has elapsed, it will when displaced be as pure as ordinary shallow spring water. If it be found that the depth of the active soil effecting this change is about half-a-yard, and that it contains about one-fifth of its weight of water, a quantity of sewage may sink into it equal to about 500 tons or a depth of five inches, before the water previously in the soil within eighteen inches of the surface is all displaced; and if considerably less than this proportion of sewage, say one to two inches in depth, be put on rich soil at once, though the drains from it will run freely, as they do after heavy rain, they will be carrying away the water previously in the soil, and not, as is often supposed, that just poured upon it, which may with good management be retained in the soil until in its turn becomes completely purified; and the water passing from the deep drains of irrigated land not over-manured may be as pure as that from the shallow springs of such land, all that is necessary for this result being that considerably less water be added to the soil at once than it previously contains, and that excessive manuring be avoided. During rapid vegetation an additional purification of the sewage matter takes place from actual contact with the growing plants on the surface.

LEYTON, WALTHAMSTOW, WOODFORD, AND WANSTEAD FLORICULTURAL SOCIETY.

The exhibition of the present season took place on the 4th ult., in the Drill Room, Marsh Street, Walthamstow, a place, we regret to say, quite unfit for the purpose, by reason of the insufficiency of light. Many good things, indeed, were scarcely visible, and such as could be seen were seen at a great disadvantage. It was, as respects contributions, an excellent gathering, not wanting in variety, and comprising many first-class subjects.

In the class for six stove and greenhouse plants, first and second, J. G. Wilkins, Esq. (gardener, Mr. John Ward). In the class for four ditto, first, J. G. Wilkins, Esq.; second, J. Carey, Esq. (gardener, James Dover). Zonal geraniums were admirably shown by Mr. Ward for J. G. Wilkins, Esq.; in the first six from this cultivator were Julius Cæsar, Lord of the Isles, and Emily Licau, beautifully grown and in perfect condition of flower. Second, Mr. Dover's lot, from the garden of J. Carey, Esq. Six fuchsias, first, S. Millington, Esq. (gardener, R. Dorling); second, J. Carey, Esq.; third, E. Venables, Esq. (gardener, James Freeman). Six ferns, first, G. Wilkins, Esq.; second, J. G. Barclay, Esq.; third, T. Thomasset, Esq. (gardener, Mr. Sandford); fourth, A. Booty, Esq. (gardener, G. Walsey). Six fine-foliaged plants, first, J. G. Barclay, Esq.; second, J. Phillipot, Esq., of Stamford Hill (gardener, J. Wheeler). Single plant in flower, first, G. Wilkins, Esq., with *Allamanda Hendersonii*, showing the very skilful treatment of Mr. Ward, who handles such subjects admirably; second, J. G. Barclay, Esq., of Leyton (gardener, D. Donald) with a fine *Statice imbricata*; third, S. Millington, Esq., with a specimen fuchsia. Twelve spikes gladioli, first, G. Whitbourn, Esq.

of Ilford (gardener, James Douglas); a fine lot. Six caladiums, first, — Fowler, Esq., of Woodford (gardener, S. Chambers); neat, small specimens. Six cockscombs, first, G. Whitbourn, Esq.; fine heads. The best four ditto from the same; second, A. Booty, Esq.; third, S. Millington, Esq. All the cockscombs shown were good. Six miscellaneous plants in flower, first, G. Wilkins, Esq.; second, C. Fowler, Esq., of Woodford (gardener, S. Chambers); third, J. Carey, Esq., Wanstead. Twelve varieties of verbenas, first, Miss Turner, of Leyton (gardener, Mr. Murray); second, H. Hughes, Esq. (gardener, B. Porter); third, T. Thomasset, Esq., Walthamstow. The best asters came from Mr. Thomasset's garden; the next best from Mr. Fowler's. Twelve varieties roses, first, H. P. Hughes, Esq., with a very superior lot for the time of year; second, J. G. Barclay, Esq.; third, A. Borwick, Esq.

Cut Flowers were shown by Messrs. Wilkins, Thomasset, Fowler, Phillipot, Millington, Carey, and others, and obtained for their gardeners the praise due to work well done, for this was a particularly attractive and interesting part of the exhibition. Dahlias were scarcely equal in point of merit to many other subjects; the best were from Miss Turner's garden; second, Mr. Fowler; third, Mr. Barclay. Designs for gardens were few, but there was one from Mr. Sandford, gardener to T. Thomasset, Esq., which well merited the first prize awarded it; the design being good, and capable of practical application, and the mechanical part of the work well done. Dinner-table decorations were few. The best came from Mr. Sandford, gardener to T. Thomasset, Esq.; second, Mr. Dover, for G. Carey, Esq.

Fruits were abundant and fine. Three bunches black grapes, first, F. Whitbourn, Esq., Ilford (gardener, James Douglas); second, T. Thomasset, Esq.; third, Miss Turner. Three bunches Muscats, first, T. Thomasset, Esq. Three bunches white, first, T. Thomasset, Esq.; second, — Simmonds, Esq.; third, H. P. Hughes, Esq. Melons, cherries, peaches, nectarines, plums, &c., were shown in variety, and in fine condition, by the respective gardeners to Messrs. Barclay, Carey, Thomasset, Whitbourn, Borwick, Booty, and others. The best mixed collection came from Mr. Barclay's garden, and comprised three fine bunches of grapes, two dishes of plums, and a fine dish of pears; second, T. Thomasset, Esq., who had cherries and peaches in extra fine condition. These two lots were highly creditable to their producers, Mr. D. Donald and Mr. Sandford. Cucumbers were not so good as we expect to see in a competition where gentlemen's gardeners are conspicuous. The best came from F. Whitbourn, Esq., the variety Dale's Conqueror, a smallish but very neat and good variety. Vegetables were in no respect remarkable for either variety or quality. Amateurs and cottagers exhibited some attractive and well-grown plants in flower, besides fruits, vegetables, and miscellanies.

KINGSTON AND SURBITON HORTICULTURAL SOCIETY.

This society's second exhibition for this year was held on the 4th instant, in the spacious Drill Hall of the 12th Surrey Rifles, through the liberality of the commanding officer, Col. Cochrane, a kindness which cannot be over-estimated, for a better-adapted place for holding autumnal shows is not in existence, and it is far preferable to canvas at this time of the year, when heavy dews and showers hang about and do not dry up so quickly as they do in the summer. Most of the classes were well represented by cottagers, amateurs, and gentlemen's gardeners. Those for amateurs and gardeners were confined to cut-flowers, fruit, and vegetables, while for cottagers were added prizes for window-plants in addition to those for flowers, fruit, and vegetables. Before going through the different subjects staged for competition, it will be as well to notice two banks of plants kindly contributed, not for competition, by Messrs. Thomas Jackson and Sons, and which contained some of the choicest specimens for which their nursery is justly celebrated. Amongst them were a remarkably fine plant of *Alocasia metallica*, some immense masses of *Aspidistras* and *Dieffenbachias*, good plants of *Dracæna australis* and *D. Cooperii*, a very handsome kind with beautifully recurved leaves of greater breadth than *D. terminalis*, besides several large ferns and other specimens. The beautiful *Yucca aloifolia variegata*, and an immense *Dasyliion acrotrichum*, one of the finest in this country, were conspicuous amongst a host of kindred subjects, palms and ferns too numerous to mention with a few fine specimen heaths. The best were *E. Austini*, *E. Marnockii*, and *E. Douglasii*. The same firm also sent a lot of the different varieties of Japanese Lilies and the Variegated Maize, which set off and gave the tables a very beautiful appearance. A very beautiful group of ferns and foliage plants came from the gardens of the President, and one from W. Harman, Esq., Norbiton Place. For twelve cut roses, Mr. Richardson (gardener to G. Beard, Esq., Long Ditton), first, with as fine a lot as could be shown at this time of the year; the sorts were *Gloire de Santenay*, *John Hopper*, *Sénéateur Vaisse*, *Charles Lefebvre*, *La Reine*, *Gloire de Dijon*, *Lerd Raglan*, *Madame Vidot*, *Louis XIV.*, *Madame Charles Wood*, and *Maréchal Neil*; second, Mr. Parsons (gardener to W. Odams, Esq., Isleworth), with good blooms of *Victor Verdier*, *Alfred de Rougemont*, and *Charles Lefebvre*; third, Mr. Lowman (gardener to W. Harman, Esq., Norbiton Place). Dahlias were not so good as might have been expected; first for twelve, Mr. Parker (gardener to F. Hammersley, Esq., Coombe Wood); second, Mr. Lowman, and third, Mr. Parsons. Messrs. Jackson and Son, sent several stands of magnificent blooms, and some filled with fine asters. First for twelve Asters, Mr. Parker; second, Mr. Lowman; equal third, Mr. Parsons and Mr. Batty (gardener to W. Baynes, Esq., Surbiton House).

The class for twenty-four kinds of cut flowers brought out some capital stands, which added very considerably to the beauty of the show: Mr. Parsons first, with a distinct lot, amongst them were some fine blooms of *Lilium auratum* and white Water Lilies; second, Mr. Ireland, with a grand boxful: prominent were fine spikes of *Gladioli*, *Lilium lancifolium rubrum* and album, and some fine bunches of *Roses* and *Gloxinias*. Messrs. Jackson sent a box containing thirty or forty kinds very tastefully arranged; amongst them were three spikes of *Eucomis japonicus*, which filled the air for some distance with its rich perfume.

Fruit was remarkably good, and the competition for six dishes was more spirited than for any other class in the hall. Equal first, Mr. Gray (gardener to W. Harman, Esq., Norbiton Hall), and Mr. Bailey (gardener to Rev. E. Phillips, Surbiton). Mr. Gray had a noble Queen pine, which must have weighed close upon five pounds, and some good dishes of peaches and nectarines. Mr. Bailey's chief strength was in his grapes, both black and white, which were first-rate. The collection also contained the best peaches in the show, and a very fine dish of Pitmaston Orange nectarines, wrongly named *Violette Hative*. For Melons, first, Mr. Mill, with *Trentham Hybrid*; second, Mr. Leo (gardener to J. W. Sandilands, Esq., Surbiton Hill).

For the best twelve vegetables, first, Mr. Lowman, with good onions, beans, tomatoes, celery, and endive; second, Mr. Richardson, with a splendid lot, his beetroot and savoy being particularly fine.

The fruit, flowers, and vegetables exhibited by the cottagers reflected the highest credit upon them, particularly when the amount of garden-ground attached to the cottages in the neighbourhood is taken into consideration, thus showing that when proper encouragement is held out to them for bringing forward the produce of their skill in horticultural affairs, they deserve better consideration at the hands of managers of Horticultural Societies than that which is usually accorded to them. The worthy president, W. Harman, Esq., offered liberal prizes for the best-kept cottage garden; and the neatness, order, and good management of the gardens in the possession of the four prize-takers were all that could be desired.

First-class certificates were awarded to Messrs. Jackson and Son for *Aerides Warneri*, which they staged with a group of other orchidaceous plants, though not for competition; and to Mr. Breach (gardener to W. Horne, Esq., Berrylands), for a very fine seedling pear, *Lord Suffield*.

The judges of the different departments were, Mr. McWilliam, Kingston; Mr. Wiggins, of Isleworth; Mr. Rowe, Surbiton Hill; Mr. Gray, Mr. Parker, Kingston Hill, and Mr. George Gordon, Hampton Wick.

LEA BRIDGE HORTICULTURAL SOCIETY.

The third exhibition by the Lea Bridge Society was held in a tent beside the railway station, on the 2nd ult. It was highly attractive, and was visited by a large number of persons. On entering the tent the attention was arrested by a large and beautiful bank of fine-foliaged plants, such as palms, ferns, begonias, &c., supplied by Mr. Prestoe, of Victoria Park. At the further end of the tent was a group of similar plants from Mr. Donald, gardener to R. Barclay, Esq., of Leyton. Another beautiful group was supplied by Mr. Forsyth, of Brunswick Nursery, Stoke Newington; also from the same a stand of twenty-four varieties of verbenas.

In the class for twelve dahlias, first, Mr. Matthews, who had good blooms of *Leah*, *Miss Henshaw*, *Andrew Dodds*, *Chelsea Hero*, *Donald Beaton*, *Norfolk Hero*, *Lady M. Herbert*, *Bob Ridley*, *Etonia*, *Stella Colas*, *Juno*, *Golden Admirer*. Second, Mr. B. Dent, with *Mrs. C. Waters*, *Helen Potter*, *Triomphe de Peq*, *Leah*, *Stella Colas*, *Ne Plus Ultra*, *General Jackson*, *Scarlet Gem*, *Lord Derby*, *G. Brown*, *Favourite*, *Bullion*. Third, Mr. Fenn, with *Miss Henshaw*, *Lord Derby*, *Andrew Dodds*, *Miss Roberts*, *Norfolk Hero*, *Juno*, *Triomphe de Peq*, *Miss Butler*, *Lord Palmerston*, *Chancellor*, *Charles Turner*, *Etonia*. In the class for six, first, Mr. Bent, with *Leah*, *Lord Derby*, *Helen Potter*, *G. Brown*, *Favourite*, *Scarlet Gem*. Second, Mr. Matthews, with *Bob Ridley*, *Lady M. Herbert*, *Andrew Dodds*, *Charles Turner*, *Lady Elcho*, *Fanny Purchase*. Third, Mr. Fenn, with *Lord Derby*, *Miss Butler*, *Miss Roberts*, *Juno*, *Andrew Dodds*, *Favourite*.

The display of asters was good. In the class for twelve, first, Mr. Matthews; second, Mr. Higgins; third, Mr. Fenn; fourth, Mr. Stillwell. In the class for six, first, Mr. W. Stillwell; second, Mr. R. Stillwell; third, Mr. G. Carr. In the class for three, first, Mr. C. Matthews; second, Mr. Ruse; third, Mr. Summers. The pot asters were, generally speaking, well grown; we hope always to find plants encouraged as well as cut flowers of this useful autumnal subject. Six varieties of verbenas, first, Mr. Barrington; second, Mr. W. Stillwell; third, Mr. C. Tyler. Six varieties zonal geraniums, first, Mr. G. Matthews, with a very fine lot; second, no name attached; third, Mr. Summers. Twelve bunches cut flowers, first, Mr. C. Tyler; second, Mr. R. Stillwell; third, Mr. Silverlock. Six gladioli, first, Mr. Matthews. Three fuchsias, first, Mr. Matthews; second, Mr. Ruse; third, Mr. Fenn. In the first prize lot a plant of *Queen of Beauty* worth making note of as particularly good. Single standard fuchsia, first, Mr. Tyler; second, Mr. Spillua; third, Mr. Ruse. Three balsams, first, Mr. Ruse; second, Mr. Matthews. Mr. Summers took first place in the class for six *calceolarias*. In the class for twelve miscellaneous plants, first, Mr. Tyler; second, Mr. Barrington; third, Mr. Summers. Three ditto, first, Mr. C. Matthews; second, Mr. Tyler; third, Mr. Barrington. Six roses, first, Mr. Higgins; second, Mr. Barrington; third, Mr. Silverlock.

Designs for gardens were good, Mr. Powell taking first place for one on a large scale; second, Mr. G. Carr; third, Mr. Gillard. In a room apart from the general exhibition was a display of floral decorations for the dinner table. Mrs. R. J. Hendrie presented a silver cup for the best display of this kind. This was won by Mr. Matthews; second, Mr. Spillua; third, Mr. Bishop. The usual fault of too much colour was largely prevalent in this competition. There were also some good collections of fruits and vegetables, Mr. Ruse taking first place with a pretty display.

WOLVERHAMPTON HORTICULTURAL SOCIETY.

The second show of the season was held on Tuesday, August 27th, in the grounds attached to the residence of G. L. Underhill, Esq., at New-bridge. There were three tents, the first, a very extensive one, being devoted to gentlemen's gardeners, who exhibited a miscellaneous collection of stove and greenhouse plants, which, however, were scarcely up to the mark. The best things we noticed in this tent were some noble pots of *Lilium*, exhibited by R. S. Walker, Esq. (Mr. Johnson, gardener). Fine-foliage plants by J. S. Rutter's gardener. Some handsome zonals and some good greenhouse plants by Mr. W. Allsop, gardener to G. H. Perry, Esq. There was a keen competition for the grape prizes, which, however, resulted in each case in favour of Mr. Fellows's gardener, Mr. Langley's gardener being second. The black grapes were not, however, up to the mark in colour. There were a few boxes of cut flowers that were pretty good; but the vegetables were very poor, and were very decidedly inferior to the amateurs' collection. The second tent contained the amateurs' productions, and was well filled, and far superior to any previous show, the improvement being very marked. Mr. W. A. Green had a very pretty collection of stove and greenhouse plants, ferns, and begonias, and Mr. Forsyth some handsome fuchsias, roses, and zonals. There was a large quantity of cut flowers, bouquets, and vegetables of good quality. A stand for table decoration, exhibited by Mr. Green, was awarded an extra prize, and was much noticed. It consisted of a circular dish of about 13 inches diameter, surmounted by a smaller one, the support being in the form of an elegant spiral; the whole was made of some kind of metal and grained dark walnut. The third tent was filled by the contributions of Messrs. Lowe, nurserymen, consisting of a fine selection of all the most useful varieties of stove and greenhouse plants, with several of the choice novelties of the day.

THE ST. NEOT'S AMATEUR AND COTTAGE HORTICULTURAL SOCIETY.

The third annual show of the above society was held on Wednesday and Thursday, the 28th and 29th ult., in the beautiful grounds of Samuel Day, Esq., adjoining the spacious nurseries of Messrs. Wood and Ingram, which, having undergone a marked improvement since last year, and being in the very height of their floral beauty, afforded a very pleasant promenade for visitors. The Llynbury brass band was in attendance each day. The weather on Wednesday was everything that could be wished for, and crowds of rank and beauty assembled to view the flowers, fruit, and vegetables, which were arranged in three spacious marquees, two of which were kindly lent by Potts Brown, Esq., of Houghton, and one by F. Welstead, Esq., of Stonely; but on Thursday the rain during the day prevented many from paying a visit to the show. Nevertheless the receipts at the gate were very satisfactory.

We are glad to say that this society is steadily advancing; the increased number of exhibitors and the improvement in quality of the productions exhibited upon that of last year, especially amongst the cottagers, testify that the society is doing some good towards the advancement of the labouring classes.

It may be interesting to some of the readers of this Magazine (especially to those concerned in the management of such societies), to know how this society is carried on; it being supported by annual subscribers of from 2s. 6d. to £1 1s., thus affording the means for all classes to further the object of the society, namely, the improvement of cottage gardening. Its officers consist of a president, treasurer, two secretaries, and a committee of twenty-seven members, out of which are chosen a sub-committee of five to manage the show. The society gives an opportunity to exhibitors of all classes to compete. It offers upwards of 400 prizes, out of which number 230 are devoted to cottagers, whose productions are admitted free. The schedule is formed into seven divisions, viz.: Division A, for amateurs who have greenhouses or hothouses; B, for amateurs not possessing either of such houses; C, for cottagers employed as gardeners, assistant gardeners, or gardeners' labourers, and who occupy more than a rood of land; D, for cottagers who do not occupy more than a rood of land; E, window gardening for cottagers, gardeners' labourers, and artisans; F, for ladies; G, fruit and vegetables for divisions A and B. By this method all exhibitors are set upon an equality.

In passing a few remarks upon the productions exhibited, it would be well to take them as they stood. In the first tent were arranged divisions A, B, and E. Division A was well represented; the plants shown were a decided improvement upon those of last year, especially the ferns. Five sets were put up for competition, all well-grown plants. Mr. W. Rachelous, gardener to G. W. Rowley, Esq., gained first prize; W. Medland, Esq., second. J. J. Evans, Esq., put up a collection of twenty-four ferns, small plants, but in good condition, which were highly commended. Two seedling variegated primulas, exhibited by Mr. W. Rachelous, were the admiration of all who saw them, and richly deserved the extra prize awarded them. The flowering and foliage plants were well competed for: Mr. Thomas, gardener to G. O. Newton, Esq., gained first prize in each. Exhibitors of balsams, cockscombs, fuchsias, and zonal geraniums came forward in great variety, which rendered a lively and pleasing appearance to the show. The cut flowers were excellent: Mr. J. Pell, gardener to Rev. J. R. Moorson, of Southoe, took the first prize for twelve dahlias; second, Mr. Rachelous. Asters were exhibited in great quantity: Mr. Last, gardener to Sir William Booth, Bart., gained first prize in each class. Roses were also good, Mr. W. Rachelous having obtained the first prize for twelve, and Mr. D. Sewell the first prize for six blooms of great merit. The varieties of cut flowers in bunches were good, and assisted greatly towards enhancing the beauty of the show.

The amateurs in division B came forward with their usual spirit; the plants and cut flowers exhibited by them showed that they all worked hard to gain a prize, the competition being so close, which reflected great credit upon the exhibitors. The prizes offered for window gardening were well competed for, and showed a steady increase upon that of last year.

In a second tent was arranged the fruit, which for quantity and quality has not been surpassed by former years. The arrangements of the table were highly creditable to the committee. The dinner vases, bouquets, fern-cases, and aquariums were arranged down the centre of the table, and the fruit each side, which gave a very pleasing effect. The grapes shown by T. H. Murfin, Esq., were well deserving the first prize awarded to them. Mr. Last, gardener to Sir W. Booth, Bart., put up two nice bunches of Black Hambro grapes, as did also W. W. Abbott, Esq. W. Medland, Esq., gained first for white grapes. Messrs. Wood and Ingram exhibited two handsome bunches of Black Hambro' and one of the Canon Hall Muscat (not for competition). W. W. Abbott, Esq., put up a dish of very fine Goliath plums, which gained the first prize. Mr. Last also put up a handsome basket of fruit, six varieties, for which he gained the first prize; W. W. Abbott, Esq., second. Mr. T. Plum, fruiterer and confectioner, exhibited a splendid basket of fruit, not for competition, the arrangement of which reflected great credit upon the exhibitor. The ladies' dinner vases and bouquets were the admiration of all, and were well competed for. Mrs. W. Atkinson gained first for hand bouquets; Miss Medland, second prize. Mrs. Atkinson, first, for bouquet for vase; Mrs. D. Sewell, second. Mrs. Sprugg, first, for dinner vase, flowers only; Mrs. Joyce, second. Mrs. Joyce, first, for dinner vase, fruit, and flowers. Round the outside tables were arranged the vegetables; the potatoes were very fine. W. W. Abbott, Esq., exhibited a nice basket of vegetables. In the C and D divisions the show of vegetables was excellent. James Taylor put up a well-arranged basket of vegetables. The cut flowers were good in this division. One of the most attractive features of the show were the nose-gays of garden and wild flowers exhibited by school-girls, for which the society offers ten prizes, and five for dishes of wild fruit, for school-boys. The duties of judges were most ably discharged by Mr. Petfield, gardener to G. Thornhill, Esq., of Diddington, and Mr. Cooper, gardener to D. Veasey, Esq., of Huntingdon.

The great success which has attended the exhibition, and the admirable arrangements made by the committee for the carrying out of the show, are matters agreeable to remember, and we trust that each year their efforts will be crowned with the same brilliant success. W. F.

NOTES ON HOLLYHOCKS AND ASTERS.

I hope they of the cloth will pardon an amateur if he gives a few ideas which have floated confusedly in his brain for the last few weeks. I wish to speak on the desirable properties of one or two good old flowers, and to point out a few particulars in which our accepted standard might, I think, be improved.

The HOLLYHOCK is a very good old flower, and, as all will admit, an indispensable. Now, what is a perfect hollyhock? Many, nay most, would say that which is most double, and that which carries the best guard-petals, and so on. All this is very well; but I have got to consider that, for general garden decoration, another quality must stand first. I had a respectable batch of seedlings in bloom myself this year, and I chose one, a white flower with purple bases to the petals, and said that for its colour it must be perfect, so beautifully was the perfectly solid and hemispherical centre set on the flat disc-like circle of guard-petals; but I found it had a bad fault still, namely, a crowding of the flowers on the spike, which had three bad results—first, that they injured each other; second, there were never more than three or four out at once; third, now the first bloom is gone, there are no more.

What I feel to be of most importance in general decoration is this last quality; for next to this plant is another, inferior in the individual flower, but on which, before the first blush of bloom is anywhere near spent, a second lot is opening equal in every respect to the first, and I shall hope for a third yet. Surely, then, this is a quality which for garden decoration ought to stand at a high value. This result will only follow if the first thing mentioned is avoided, so that we have a thinly-furnished spike, which will leave the blooms at the right distance at once; and while this can be got, how foolish it is to have to thin your blooms! In this spike you will always observe a number of smaller buds, which will open after the others are gone. And this spike is always better furnished with open blooms than any other, for the strength which merely went to produce a solid bunch of indistinguishable half-rotten blooms is nicely distributed over a foot and a half or more of the spike. But you say, "Oh, that is nothing; why, only let me have a bit of good well-manured land, and thin the blooms properly, and give liquid manure and shade" (and I know not what else), "then you shall see a yard of spike all in its prime at once." Yes, but what is the worth of this when we want that which is easily grown, and is little trouble, instead of a thing which, with *trouble enough*, will do for exhibition? For the general use of the garden, then, we want, as well as good form and colour, a continuous bloom and a spike no more than properly furnished. It is worth observation that the blooms on these spikes are not generally of that excessive solidity that others are, but are nice and hemispherical, with the guard-circle well developed, which is altogether an advantage.

THE ASTER.—I feel that in this there is considerable room for improvement yet, and I shall try myself to get such improvements as seem most desirable. Firstly, and above all, we want all our blooms to be incurved, not only moderately, but entirely. There are some colours which I have seen in this form to perfection,—mostly, however, as far as I can remember, they are either tipped or striped, light blue and white, darker blue and white, white more or less tipped with blue, pink and white striped. The tipped ones are perfect miracles, too good for vulgar eyes to look at, and I think I am nearly right when I say that nine out of ten of real florists would cease to have any interest in the reflexed forms if they could get the incurved as perfectly as it is to be had in the above colours. We only want the soft rose-colours, dark blues, pinks, and whites of this form, and then we may rest.

Now I do not know whether I am quite right, but, as far as I have seen, there is a tolerably distinct relation between colour and habit. Thus I have seen pink incurves; they were very coarse every way, double the proper height, the petals thin and shining, the margins reflexed, and altogether not the thing. There is also one fault in the incurved ones, as far as I have seen: they are too narrow and upright. We want a good sturdy, bushy growth, about one foot to fifteen inches high. I have a fine white, neither incurved nor reflexed; but its fault is its height, running two feet to two feet six. They are indeed noble bushes to call asters at all; but it will not do if we have to put sticks to them. On the other hand, they should not be so dwarf as some are, for then the rain spoils them so, unless you wish to pot them. These, then, are some of the defects which I shall try in my own little way to remedy, and I hope the weather will be fine and let the pollen well out.

I will close with a few notes on my way of growing asters, which may be useful to some; and first as to saving seed. In a fine autumn this will be produced from one to three or four dozen in each flower, however double it is; and this seed should

not produce one plant sensibly worse than the parent. I sow in pots, about the usual time in April, and when they are big enough plant them out in the kitchen garden, about eight inches in the rows by fifteen inches between the rows. Here they stand until the bloom-buds are on the point of showing colour, when they may be taken up with good balls, and be planted where wanted. It generally becomes desirable to remove a few choico geraniums, &c., about this time, and the asters take their place very well. They must then have one watering, and in a day or two they will forget all about the moving, and bloom on as well as they would have done if they had been left alone. I have not said anything of saving seed in a bad season. There are three ways: first, to take up the best and lay them by the heels in a pit, then draw the light down, and let them alone to seed. Second, pot a lot early, say about the end of July; the pots will be full of root before they bloom; then put them in the driest, lightest, hottest place you have, say under a south wall; when they are in full bloom, leave off watering, and they will in due season produce seed. Third, plant a lot in a similar situation about the end of July, and let them take their chance. I believe the second mode is the best, and is similar to that whereby the best foreign seed is produced.

Finally, I would say to every one, grow your own seed. You have no idea of the different feeling there is in knowing what you sow, compared with that of having to trust to foreigners for it. Of course, whenever you see something superior advertised, make use of it, and see if it is worth keeping. I feel that if the aster is a good and well-appreciated thing now, it would soon be very much more so if a little care of this sort were given to it. A. DAWSON.

THE BEDDING DISPLAY IN BATTERSEA PARK.

Though we have already agreed that 1867 is to be counted with the bad seasons, it must be said in respect of the sub-tropical movement that the experiences of the present season detract nothing from its splendour, add nothing to its difficulties, or furnish a single argument against its adoption, where circumstances permit of its being carried out in its integrity. The present season's display is in many respects more complete and splendid than any that have preceded it. Yet there are exceptions to the completeness and general splendour of the scene, for some few subjects have been slow to grow and shy to flower, and in these cases a far less satisfactory result has been attained than in former experiments in sub-tropical gardening. Perhaps permission should be asked for speaking of Battersea Park in this way; but it is certain that Mr. Gibson's spirited development of new ideas in out-door decorations so far transcends the customary routine of bedding display that we can only think of the sub-tropical movement while here; it is the peculiar attraction of the place, the special glory and joy of the presiding genius.

I landed on the steamboat pier from one of the Citizen boats, and took my way directly up the drive from the river. For visitors from London the Thames is the best highway; the voyage is a pleasant one, with small risk of sea-sickness, and the series of new bridges with which the Thames is spanned, at the distance of only a furlong or two apart, all the way, afford abundant entertainment, and ought, I think, to make every Cockney proud of the river. It is not quite a prepossessing entry to Battersea Park, but it is a convenient one; for the drive directly up from the river soon brings us to a little temple of fancy iron-work at a point whence several roads diverge, and there we can at once strike into the avenue, and, while enjoying the shade and the beauty of the shrubberies, make our way by a quick route to the sub-tropical garden. I noticed many examples of the beautiful *Althea frutex*, with white, crimson, rosy, and purple flowers, and I was lamenting the deficiency of such things as *Cratægus*, *Sorbus*, *Pyrus*, *Malus*, and others that at this time of year are glistening with brilliantly-coloured fruits, when I met Mr. Gibson, and began to unfold my mind to him on the subject. He at once lamented with me that he had no Siberian crabs, no gaudy clouds of barberries, no great sheets of cotoneaster, dotted with scarlet on a ground of darkest green; "for," said he, "if we had them there would be perpetual depredations, and boys, intending only to take a twig with a few bright berries, would, in the hurry to tear them away without being caught, tear the trees themselves to pieces, and we keep such things out of sight because we will not lead them into temptation." So we learn from such a remark—the fruit of experience—that when we criticise a public place we must take into account many matters that are not advertised to us in its appearance ere we can attain to the full scope and purpose of the designer, planter, and manager, and that public morals have a direct relation to the status of art and the range of knowledge. Very soon afterwards we met M. Barillet, the Emperor's head-gardener, who was accompanied by two ladies, and we now made a large party of inspection, and went into the matter earnestly, discussing many points of taste and culture; and M. Barillet was every moment loud in his praise of the beauties of this place. He pronounced it better in many respects than some of the best bits of sub-tropical gardening in Paris, and was especially charmed with the groups of palms, tree-ferns, *Philodendrons*, and *Aralias*, which are indeed wondrous to look upon, not only because of the beauty and great size of many of the plants, but because of their extreme naturalness, for in truth they spring out of the ground as freely and happily as if to the manner born, natives of the place. The perfection of art has been attained in the concealment of art; and we do not think to look for the rim of the pot amongst the grass while admiring a *Phoenix* or a *Sabal* or a *Latania*, so appropriate do they appear to the spots they occupy, and so healthy and fresh, as if the out-door atmosphere of England were sufficient both in heat and moisture for them.

Having roamed about in various ways, we came into the sub-tropical by way of the drive nearest to Surrey Lane. I think the gate on this side is called the "South-west Gate." At all events, we came into the sub-tropical garden by way of a walk past a new series of earth-works now in

course of formation, and which are intended to serve the twofold purpose of a walk *above* the garden, to afford a bird's-eye view of it, and also shelter to the tender plants which are usually put out in the borders here. To enter the garden by this same walk is to experience a sensation; for you come direct upon a great bed of *Ferdinandia eminens*, which is one of the finest spectacles in the way of foliage in the place. The plants may be some ten feet high or less; the leaves are immense, the colour a peculiar grayish green; and the habit of the plant altogether as distinct from everything commonly met with in English gardens as can well be. Turning to the left from this point, we may very conveniently and agreeably traverse the whole of the garden by the winding walk which surrounds it. The plan of the garden will be found, drawn to scale, at page 382 of the GARDENER'S MAGAZINE for the year before last (December 23rd, 1865), and by reference to that any particular bed or group may be easily found. On the way round we meet with groups of *Cannas* everywhere. The *Canna* is the leading plant in this sort of work, as the geranium is the leading plant for flat bedding where colour alone is aimed at. On the way we meet with a long bed of *Wigandia caracasana*, edged with the blotched-leaved Irish ivy, a rich display of leafage. On the left a bed of *Erythrina* in flower, the best sorts in the bed being *ruberrima* and *ornata*; this bed is edged with variegated geranium. Presently a group of gigantic tobacco plants attracts attention; this is *Nicotiana Wigandoides*, and well named, for the leaves are *Wigandia*-like, and for that reason the species is one of the most valuable of the family of tobaccos for ornamental purposes. On the right a bed of *Luna*-like zonals, the leaf large, green, with cinnamon zone, the flowers scarlet; the name is *President Lincoln*. It is coarse, and may be put down as undesirable. Presently we come upon one of the best bits of colour in the place; it is *Geranium Crystal Palace Gem*, which has been much recommended in our *Geranium Papers*: the leaf is splendidly golden, and the flowers are soft cerise; there can be nothing fresher, purer, or more pleasing of its kind. The geranium is edged with a beautiful dwarf *Lobelia* called *Pumila elegans*, the habit of which is dwarf and compact, the flowers light blue, one of the best varieties of blue *Lobelias* known. The margin to this bed is *Alternanthera spathulata*, which has been good, but is now passing away. Presently, on the left a remarkable bed of *Amaranthus bicolor*, which undoubtedly surpasses in splendour all known varieties of foliage bedders; the plant grows a foot or more high, makes plenty of largish leaves, the colour a blackish crimson, but the young growth is of the most intense carmine colour, and transparent and lustrous like coloured glass. *Amaranthus tricolor* has been given up in favour of this splendid species, and if it should ever again appear as good as it is this season, *A. bicolor* will be in demand beyond possibly the means of supply, for of course the stock must be made mostly, if not entirely, from seeds.* On the right, a long bed of *Mrs. Pollock*, edged with *Viola cornuta*, which has been good. Unfortunately Mr. Gibson selected *Bennett's variety*, which is a fine thing where it does well, but in so many places it has the bad habit of dying off, that it must soon give place to the paler flower, but safer and healthier variety introduced to cultivation by Mr. Wills. Here it will be found to be patchy, owing to the deaths that have occurred. The margin to this bed is the beautiful *Echeveria secunda*, one of the most artistic marginal plants in cultivation. A few paces farther on is the most curious and perhaps the most interesting bed in the garden. It consists of large plants of the curious *Echeveria metallica* and *Sempervivum arboreum*, surfaced with that pretty *Sedum glaucum* which Mr. Salter distributed a few years ago. The edging consists of *Sempervivum montanum*, beyond which is a margin of the pretty crustaceous-leaved *Saxifraga pectinata*. Farther on is a composite bed comprising blocks of *Rollisson's Unique* and *Paul's Fairy Queen* geraniums, with dividing lines of *Veronica incana*, one of the most peculiar and distinct of all cold silvery-leaved plants, the colour a bluish gray. Here too are lines of the *Golden Feather Pyrethrum*, which is now acquiring too green a hue to be desirable, but which all through the season, here as elsewhere, has been good.

Somewhere about this point we find ourselves in the midst of tropical plants of all kinds, and conspicuous amongst them is a bed of *Musas*. Yes, a bed of *Musas*; planted out, growing freely, actually making fruit and less torn than usually seen in their native soil, as avowed by Mr. Gibson, who is familiar with their appearance in their proper tropical homes. The tallest and handsomest plants are those of *Musa rosea*, which are ten feet high, with abundance of fresh bright leaves, very few of which are torn, and many spikes of bright rosy flowers. On one of these plants I saw and pointed out to our friends a bunch of real bananas an inch or more long, the first ever grown in the open air of this country no doubt, but a *bona fide* out-door growth so far; of course nobody expects them to finish and become eatable. In the same bed are plants of *M. Cavendishii* two to three feet high, which have scarcely flowered. All these *Musas* are making suckers freely, and in some cases the suckers of the season have flowered; this is the case with several of the *M. rosea*: it proves that the plants of the tropics are accommodating, and that our climate is not so bad as it seems. The surfacing of the bed is the elegant grass *Elymus glauca*.

From one surprise to another. Go and see, if it be possible, the bed which occurs next beyond the *Musas* on the left hand. It consists of *Coleus Veitchii* edged with *Golden Feather Pyrethrum*, and is indeed a remarkable piece of colouring. Close beside it, a similar sensational affair, is a bed of *Colous Verschaffeltii* edged with *Centraea gymnocarpa*. These combinations are extremely simple, but they are so rich that nothing can surpass them. Immediately after seeing such colouring, geraniums look tame and weak, and it is not desirable therefore to have any such in the immediate vicinity of these beds. A pretty circle on the left next takes our notice. It contains a great Maltese cross of *Amaranthus molancholiosus* filled in with *Centaurea ragusina*; the cross is enclosed in a ring of *Lobelia pumila elegans*, and the margin of the bed is *Saxifraga setacea*. Another charming bed, consisting of *Duchess of Sutherland* nosogay for centre, then a ring of *Pink Stella*, and *Lobelia pumila elegans* to finish off with.

We are again in something like a tropical jungle, banks of *Cannas* everywhere, clumps of *Wigandias*, *Nicotianas*, and other stately plants. Particularly noticeable are three beds near the walk, consisting of a small circular bed, with oblong beds on each side of it. These beds are worth finding by connoisseurs in bedding, and may be found by taking up the thread of this narrative from the earth-work and the bed of *Ferdinandias*. Here is *Lo Grand nosogay* put to the final test as a bodder, and wearing

* I say "mostly" advisedly, because all those coloured-leaved annuals may be increased by cuttings after the seedling plants are sufficiently advanced to allow of their being topped by the propagator; and when *Perilla* and *Amaranthus melancholicus* are required late in the season, cuttings make plants much quicker than seeds.

well, and justifying the high character it has enjoyed from the first. It is, however, rather weedy-looking now, owing to the excess of humidity lately. It is enclosed with a belt of Golden Vase, and edged with *Sempervivum*. In the centre bed is a clump of *Souvenir de Sir Joseph Paxton*, a most beautiful variety, with a ring of *Euonymus radicans*, and an edging of *Sempervivum Californicum*. A little further on in the same direction a splendid bed of *Dracona terminalis*, edged with *Centaurea gymnocarpa*, and close to this a good bed of *Caladium esculentum*, which has this season made a far less satisfactory growth than last year. On the left a great clump of *Cassia floribunda*, rather weedy-looking, but flowering freely. This is not to be recommended as a bedder; a better place for it is next a hot wall. *C. corymbosa* is perhaps better, and the more so because in a dry border in a sheltered place it may be left out all winter. Next noticeable feature a bed of mixed *Hibiscus*. Somewhere near a clump of *Nierembergia frutescens*, which M. Barillet informs me is much used in Paris, and is quite hardy there, and he is sure will be hardy here too. Observe now a great scroll of *Lucina*, edged with the variegated *Euonymus radicans*. With very little searching you may now find a peculiar and very handsome large-leaved, light green shrub, the name of which is *Grislinia macrophylla*, a relative of that *Grislinia litoralis* which has been so often recommended in these pages as a hardy evergreen shrub for warm sheltered gardens. Not far away another bed of *Draconas* of the red-leaved section, the ground-work variegated *Dactylis*, the edge *Sensation Chrysanthemum*. A bed of *Caladium Javanicum*, which is less showy than *C. esculentum*. Next a cross of *Centaurea gymnocarpa*, filled in with *Golden Fleece*, and edged with *Alternanthera spathulata*. Another surprise is a bed of *Coleus Verschaffeltii*, edged with *Centaurea ragusina*,—nothing richer in the garden. Presently a clump of *Geranium Galety*, one of the bronze zonal section; it is superb in its gold and bronze colouring, the flowers are scarlet; no fear of a failure in growing this, and hard to beat it in the class. A clump of *Caladium esculentum*. A clump of *Canna purpurea spectabilis*, which I mention more particularly to call attention to the outer band of *Solanum macrocarpum*, which is the best for blue flowers; the leaves are green and deeply lobed. Observe beside the scroll a bed of *Aralia papyrifera*, with a ground-work of *Canna expansa*, edged with *Centaurea ragusina*. Here a lesson in acclimatizing. A bed of *Centaurea plumosa* which has stood out all the winter, and is in splendid condition. We see in this the virtue of raised beds on brick foundations: extra warmth all summer, extra dryness with extra warmth all winter, and a dryness of that peculiar kind that during a summer drought the plants do not suffer, for bricks covered with soil are never quite dry. Somewhere here a margin of *Lobelia Miss Murphy*, a complete failure; kick it out. Clumps of *Monstera deliciosa*, a very peculiar and grand subtropical. A little way off from the walk across the grass you may see on the left a belt of a very much variegated plant; it is *Epilobium parviflorum*, the plant you may have read of in a report lately made on the plunging system. It is not so good here planted out as we do it in pots, but as it is there are not many hardy plants that can compete with it. Any one in want of this plant only need to wake up Mr. Salter. A nook filled with tree-ferns, a sort of dell, a bit snatched by art from the shady valleys of New Zealand. We shall surely have all the vegetation of the globe in Battersea Park soon, for *Musas* do well planted out, and tree-ferns are none the worse for plunging. At this point I began to sing a snatch of a teetotal hymn—

Glorious light has busted round us
Happy day,

but checked myself by remembering it would be a difficult one to translate to M. Barillet; the elegant "busted" might perplex us both. By a short turn aside from the regular walk round, a bank of *Neottopteris australis* in pots plunged, a sort of hart's-tongue valley for an impossible fairy-land. Oh, go and see it, go and see it; not a frond discoloured, all green as emerald, shining as varnish, elegant in a measure that makes a mere joke of any attempt at description. We all know it as a pot plant; know it! bah, we know nothing of it until we have seen this bank in a shady nook where the plant is a sort of naturalized weed, as our own lovely hart's-tongues are in the hedge-rows of our native land. *Pothos acaulis* five and a half feet in length of leaf, grand. A panel-bed of *Sunaet*, with divisions of *Blue King Lobelia*, and *Antennaria tomentosa* forming a pavement of silver to the blue, gold, and red, the margin *Echeveria secunda glauca*, the last a better variety for bedding than the common form of the plant.

Let us go on again by the path we left to look at the ferns and the *Pothos*. A circular bed of *Salmon Nosegay*, ring of *Princess Lichtenstein*, edge *Lady Plymouth*, margin of *Viola cornuta*; a splendid bed, and one that may be copied anywhere for a good feature. Presently a bed of *Coleus marmorata* and *Coleus aurea marginata*; neither of these very good. One of the grandest beds here of *Canna Limbata*, the plants twelve feet high and quite rich with flowers. Next a long bed of *Ferdinandia eminens*, with *Solanum marginatum*, filled in with *Tagetes signata pumila*, the margin *Plumbago capensis*. The last-named plant deserves more attention than it obtains from bedding people; we intend to try it for the plunging system from spring cuttings.

At this point we are so near the refreshment room that we go up that way to have a look. And well worth the journey it is. Here we have a bit of bedding of the customary pattern, colour being the principal element. The beds are set out on a semicircle of grass, and in the rear is a border of mixed shrubs, with a facing of colour. The facing of the enclosing border is in festoons; for the back row *cannas*, next *Lucius geranium*, which very deservedly is a favourite here; next *Stella*; next crescents of *Golden Fleece*—this is marked out distinctly with lines of *Viola cornuta* and lines of *Stachys lanata*; in front crescents of *Harry Hieover* and *Mrs. Pollock* alternately: an elaborate and most tasteful piece of colouring. The scheme of beds is divided in the centre by a walk, and the beds on one side of the walk are counterparts, or nearly so, of those on the other side; therefore the description of one half the scheme will suffice. No. 1 is an oblong, with a centre of *Madame Vaucher*, next to it *Waltham Lilac*, then a band of *Golden Fleece*, margin of *Cerastium*. As all the beds are edged with *Cerastium*, we will not again mention it. No. 2 is a circle of *Beauty of Oulton* and *Blue Lobelia*, mixed; this is first-rate. No. 3 is *Rebecca*, edged with *Golden Fleece*. No. 4, *St. George and Cirelet*; the last named is a good bronze zonal. No. 5, an oblong of *Sir Joseph Paxton* and *Golden Fleece*. No. 6, a circle of *Golden Fleece* and *Lobelia Blue King*. No. 7, an oblong of *Serena*, a good pink geranium, with outside band of *Golden Fleece* (on the opposite side the counterpart is *Eve*, one of Mr. Bull's good pink varieties).

We now make a sharp turn, and are in the drive which leads to the

celebrated "coffins." Now we have a boundary ribbon, consisting of front line *Stachys lanata*, the poor man's permanent silvery edging plant; next line *Lobelia Blue King*; next *Christine*; next *Gaines's Yellow Calceolaria*, which is the favourite variety here, doing better than any other on this soil; next *Stella*; next *Dahlia Napoleon*, a fine purple. In the bay formed by this waving ribbon, a bed of six whirling spokes or eccentric rays of *Coleus Verschaffeltii* and *Golden Fleece*, edged with *Centaurea gymnocarpa*, and margined with *Echeveria secunda*. I remember something of *Viola cornuta* in this affair; surely it must be between the *Centaurea* and the *Echeveria*, to separate the two grays, but I cannot say for certain. Now for the coffins. They are not so good as in former seasons. In each there is a central line of *Amaranthus melancholicus*; next a band of *Gnaphalium* or silvery *Artemisia* alternately; next *Mrs. Pollock*; next *Lobelia pumila elegans* or *Lobelia speciosa* alternating, margin of *Euonymus radicans*. The centre bed to this scheme is *Sensation Chrysanthemum*, *Centaurea gymnocarpa*, *Viola cornuta*, *Alternanthera spathulata* and *Alternanthera paronychoides*, with the *Echeveria* for edging. Here we may suppose we have finished the principal groups and beds, and there are all the *Cannas*, which abound like weeds in plenty, but not like weeds to look at. Well, this is a long story; suppose we leave the *Cannas* till next week? We will do so; the subject is too big to furnish a tag to this story; and, trusting to the indulgence of all our readers, the *Cannas* shall stand over for the present. But in the mean time, friends, one and all, see Battersea Park before the season is quite gone. Just now it is in perfection, though some things here and there may be a bit seedy. Never mind; the great and grand things are all perfect, and, while mild weather lasts, will continue so for the delight of the British public. S. H.

CUCUMBERS FOR THE WINTER.

It is somewhat singular that I should close my last article on this subject with a strict injunction to the reader to work out a thorough system of air-giving at this season of the year, in growing cucumber plants to fruit through the winter; for want of proper attention to the very same rule nearly proved fatal to some plants I had myself obtained for the same purpose, since the article above alluded to appeared. But I must tell you how this happened, and then probably all interested will say it has proved a useful lesson, as well as justified the concluding remarks of my last paper. It occurred in this way: a few days after the cucumber plants were put in, we commenced a rather heavy job in making an addition to the pleasure grounds, which quite occupied my time out of the garden; consequently the houses were left in the charge of one of my assistants, who instead of following my instructions to keep up a current of air through the cucumber house at least ten hours each day, had omitted to give any front air at all, and not much more than half enough at the back; at the same time he had kept the atmosphere of the house heavily charged with moisture, and the consequence was that in a few days a heavy attack of mildew followed, brought on by a close confined atmosphere which was superabundantly charged with water, and in which there was not sufficient movement to promote a healthy growth.

I have related this circumstance just as it occurred in practice, and from it every grower of winter cucumbers may deduce a useful lesson; for probably there is no plant which delights more in a warm humid atmosphere, providing it is sweet and pure; but as soon as the air of the house becomes stagnant with humidity for any length of time, I know of no plant that will sooner resent the injury. The importance of atmospheric moisture, as applied to growing cucumbers in houses in the winter, is amongst the principal secrets of success; for if you get the air of the house too dry, a host of red spider immediately follows, and the edges of the leaves turn yellow and are withered up, and if too moist and confined, mildew will be sure to set in, and the young fruits will damp off and fall.

Willing as I am to tell all I know about the cultivation of cucumbers in houses for the winter, after many years' experience, I cannot lay down any specific rules of management as regards the amount of air and moisture to be given, as the cultivator must be guided solely by the condition of the elements; and it is in this part of the business where the skill of the gardener is most peculiarly called into active requisition. This we know, that the greater the heat the more active will evaporation be going on from the leaves. Now there are only two agencies which supply us with heat—the sun, and that generated from the pipes, which are under command. Knowing this, the cultivator can ascertain from observation from which source the heat is derived; if from the sun, and it is possible to admit a current of air through the house, no amount of moisture in the atmosphere will ever do any harm. In fact, at such times it should be abundantly supplied; but it should not be so when we are dependent upon artificial heat to keep up a high temperature, as then we may conclude that the weather does not admit of much air being given, consequently it is not changed so rapidly, and a less amount of moisture will suffice.

From the foregoing remarks the reader will understand the importance of the advice previously given, that a thorough and efficient system of air-giving should be worked out, taking

for our chief guide the condition of the external atmosphere. As to the application of atmospheric moisture, that must also depend in a measure upon the outward elements. While clear open weather prevails during winter, air may be liberally supplied; but very much will depend in this matter upon the conveniences of the house. If a tank is in use for bottom heat, the air of that house will be less dry than the one furnished with only rubble, consequently less syringing and sprinkling of the floor will be required. As regards this point of management one thing is certain, the more heat there is given the more moisture in the air will be required, and it does not matter from which source the heat is obtained, as evaporation is nearly as great (although not quite) from one as the other.

In the application of heat which is at the command of the cultivator, there are one or two important points of management which it may be well to mention, as if this part of the business is not conducted with some amount of skill, the plants soon become weakly and unfruitful. I would particularly call the attention of inexperienced cultivators to the necessity of reducing the temperature of the house during dull, snowy, or wet weather; as when a high temperature is maintained when there is a deficiency in the usual amount of daylight, a weak and sickly growth is created, which cannot be recovered until there is a sufficiency of light to properly mature the growth. And I might specially note the importance of reducing the temperature during a continuance of frost. From November to the middle of March, a temperature of 60° by night and 70° by day, rising 5° during sunny open weather in the day, are the highest registers of the thermometer that ought to be maintained, with the most essential feature strictly carried out, to give air early in the day that the plants may enjoy a sweet agreeable atmosphere to breathe in.

I now close this short treatise with a brief reference to the young plants, taking up at the close instead of the beginning the thread of my last paper. To all young growing plants give plenty of moisture and an abundance of air, in bright mild weather, until the middle of October, when fire-heat must be given at night and during cold damp weather. Train the young plants to neat sticks until they reach the wires, and as soon as they have made three leaves above them pinch off the top, and train out the laterals neatly over the wires, pinching off all young fruit and the male blossoms as they show; but guard and protect every leaf, as winter cucumbers never make more leaves than they require: nor must they be stopped more than twice or thrice, for they make such little growth that they will not endure it. The picking off of the fruit and male flowers must continue until they are required to bear fruit. When they are in bearing give water copiously twice a week, of the same temperature as the house.

A KENTISH GARDENER.

LOBELIA SPECOSIA FROM SEED.

I don't know whether I am singular in having a great difficulty to obtain plenty of good cuttings of this useful plant, without the necessity of planting a clump on purpose to cut down to furnish a supply now, and also to take up a lot to cut from in the spring, with the risk of two-thirds of the old plants going off long before there is any possibility of turning them to any account. Such, however, is the case with me sometimes, and therefore I am not in love with lobelia cuttings. Against all the risk we must set the time spent in putting in the cuttings, tending them through the rooting process, hardening off, and other operations that cause an amount of labour which just at the time it is required can be but ill afforded. For years past I have raised the whole of my stock from seed, for I find it costs a vast deal less time, trouble, and anxiety, and for all practical purposes the plants are equally as good as they would be if raised from cuttings. Certainly I get a few with flowers a shade lighter than the bulk, and a few with a more straggling habit than plants from cuttings. To give a rough guess, and I have not had time to count them, I should say there are half a dozen of each sort to every five hundred, a number that is not worth a moment's consideration, and the plants are not at all conspicuous by the paleness of the flower or rambling growth, not being sufficiently distinct from the others to render them so. The most important point, and one which I cannot too earnestly urge, is the seed harvesting, for too great carefulness cannot be bestowed on the work. A good strain from which the seed is to be saved must be obtained, for if it is chosen from a bad one the whole affair will end in disappointment, and represent so much time and labour wasted, for the colour of the flowers will vary from the brightest shade of blue imaginable to the deepest indigo; moreover, the plants will be straggling habited. Like results will

happen, though in a lesser degree, if the seed is saved indiscriminately from the whole collection without reference to the colour of the flower and habit of the plant, even if the cultivator has the best strain in existence; for the Lobelia, like other cultivated plants, will soon run back to the normal type unless it is guarded against that by careful selection. I always save my own Lobelia seed, for I find I cannot obtain it so good and true from the trade. Mind, I do not attach the least blame to the seedsmen, for the price usually charged will not admit of their being more particular; they have to pursue the same course as the grower of turnip seeds, &c., namely, select the best types from the whole batch, and save the seed from them for sowing themselves the following season. From such sowings they produce the stock of seed which they distribute to their customers. It follows, as a matter of course, they are bound to keep back the very best, and sell the other; so that the buyer gets a similar quality to what he would do if he carefully selected the seed one year, and the next saved from the whole lot. I do not for a moment wish to be understood to say that the trade Lobelia seed is rubbish, or that it does not produce tolerably good plants of average quality; but it cannot compete with seed annually selected. I go over the whole of the plants on the place, and pick out a dozen of the best, and save from them only, and my plants cannot be readily recognized from plants produced from cuttings.

I think enough has been said about saving the seed, therefore we will direct our attention to raising the plants in as brief a manner as can be consistently adopted. I have found, after several years' observation, that the end of September is the best time for sowing the seed. Plants from spring-sown seed do not get so stout and strong, or flower so early as those raised in the autumn. The seed is sown in pans in a cold frame, and as soon as the young plants are large enough to handle, they are pricked off into other pans or boxes an inch apart, in which they remain until February or March, when they are potted off into small sixties, kept rather warm until the roots begin to touch the sides of the pots, and thenceforward are treated exactly the same as plants from cuttings.

GEORGE GORDON.

VALLOTA PURPUREA, OR SCARBOROUGH LILY.

It is not an uncommon circumstance at this period of the year to find many greenhouses, especially those belonging to villa residences, almost denuded of plants. Why it should be so, when we have numerous beautiful plants that are well adapted for supplying the vacancies, is almost a wonder. It surely must be the result of sheer supineness. These plants are wholly neglected because we do not trouble ourselves to inquire after them, relying, as we do too much, on our stereotyped practice of allowing things to remain as they are because we never saw things different. *Lilium lancifolium* and its varieties may be considered amongst the most valuable additions to our conservatories. At this season they are both grand and interesting to behold. But *Vallota purpurea* is still more striking in character and colour. The flowers of this noble plant sparkle as you behold them in the distance, being of a very bright scarlet. Why it should be named "purpurea" puzzles me, as there is not a tinge of purple about it that I can discern, unless it is when the beauty of the flower is fast fading, and then it acquires a kind of purple hue. At the present time I have several pots of this bright flower in full bloom, and I should like to know that thousands of our readers have them equally good and in sufficient plenty. I will just detail the mode of culture adopted by me, not that there is anything mysterious or difficult about it, for of all bulbs the *Vallota* is the most easy to cultivate. Some growers maintain that with these, as with the *Cyclamen*, they must not be allowed to remain dormant at any time, but kept continually growing, being an evergreen bulb. However, my system somewhat differs from that. When I undertook my present charge late last autumn, I found a great number of these bulbs potted singly either in 60 or 48 sized pots. My first treatment of them was to pack them away on their sides under the stage. In this state, without a drop of water, they remained for several weeks. I then prepared some good stiff loam, mixing with it a little leaf-mould and silver-sand. In potting I selected three of the largest bulbs; these I planted firmly in a 24 or 8-inch pot; the others were planted in lesser-sized pots according to their respective qualities. Scarcely a bulb has failed to produce flowers except a few that are very weak. Of those in 8-inch pots, each truss of bloom contains not less than five flowers, others more; some are throwing up two trusses of flowers; so that some of the pots will produce not less than two dozen blooms; so you may imagine the splendid effect they have produced.

JOHN F. McEROY.

PLANTS FOR BOWERS, TRELLISES, RAILINGS, OLD TREES, STUMPS, ROOT-WORK, &c.

To have suitable well-made bowers in a garden, and to cover trellises well, are matters of importance. Frequently the plants are badly selected; subjects are used that are disagreeable from some causes or other, and therefore we rather take an interest in gathering together those really suitable, and which in most cases merely require planting. It should be remarked that many of the plants suited for bowers, &c., are equally well suited for trailing over stumpy places, rough banks, rough rockeries, &c.; notably, the vines with which we begin our selection. The following kinds of vine are simply useful for their trailing power, so to speak: *Vitis aestivalis*, *V. Amooriensis*, *V. cordifolia*, *V. heterophylla variegata*, *V. Iaabella*, *V. labrusca*, *V. laciniosa*, *V. riparia*, *V. Sieboldii*, *V. vinifera apiifolia*, *V. vulpina*; useful for falling over rocks, for low trellises, and even for bedding out.

We ought, perhaps, to commence with the *Ivies*; for this purpose certainly nothing can equal them as evergreen coverings for bowers, &c. One of the prettiest bowers (for winter) that we have seen was covered densely with the Irish ivy. It was simply like a great isolated niche, not deep, and with no side, so that the light could play on the inside nearly as well as on the outside; the glistening verdure of the ivy was as pretty inside as outside, as the thing was placed in a position where it caught every ray of sun. It formed a most agreeable bower at a season when such things are rarely resorted to. The French make most tasteful bowers of the common ivy, even often where there is no soil to plant it. It is used very extensively to make rather wide and neat edgings to the borders, &c., in the gardens round the Louvre and many others, and also in several other ways, notably to cover with dense green sheets the iron railings. Thus, about Passy and in other neighbourhoods, some of the iron railings in front of houses and gardens are closely but densely sheeted over with ivy, except the tops of the spikes, and this forms an agreeable wall of verdure along the boulevards where it occurs, while it may also be useful in keeping out the heavier rushes of dust in summer to some extent; and, altogether, I think it is a custom which might be well adopted in suburban gardens about London, for trailing up the railings by which they are usually faced. A specimen, showing one of the many ways in which the French use the Irish ivy, was shown at the Paris Exhibition. It was a temporary plant for removal, but made to form an elegant little summer-house, about ten feet wide, a single plant of ivy being trained on what may be described as a large umbrella frame, the handle being supported by stakes, and the tub containing and feeding the roots being covered with boards, so as to form a seat. Thus a passing or even a sitting observer would not know it was grown in a tub or pot. In England we make but little use of the ivy, and for any beauty it displays with us we have to thank its own rambling disposition; but any person who looks along the railings in the Avenue d'Eylau, outside the Jardin Fleuriste de la Ville de Paris, or in many other places where tasteful houses occur, and sees how beautiful it looks covering iron railings with a dense sheet from top to bottom, as well as its many other tasteful uses which may be seen about Paris, will agree that we might make a very tasteful use of it in English gardens, and particularly in English town and villa gardens. We have, in fact, never been tired of admiring it as employed about Paris, and hope to soon see it receive equal attention from us, as our climate is even more suited to produce it in perfection. Of course, many of the beautifully marked kinds may be trained in like manner. Indeed, the various variegated ivies will soon become indispensable to the good garden of hardy plants; they are so nice for walls, trellises, or even for edgings in not a few cases. But however pretty the marked kinds may be, they can in no degree compete with the common Irish ivy as a rich green covering. Our true plan of dealing with them will be found to be in employing the best forms sparsely among the green kinds, or among other green plants. To meet with a good variegated form now and then amidst glistening green is charming; to plant a great number of them together for the mere sake of the collection is a mistake. To allow the ivy to trail over rough mounds, &c., is a favourite plan of ours, and we have even found it desirable to make mounds for this purpose in a picturesque pleasure-ground—planting specimens of *Yucca* over the ground-work of ivy, and allowing a nice tuft of a variegated sort to fall here and there over a stone, or near the edge, so that it might be well seen amongst the mass. The following kinds are amongst the best of those readily procurable in our gardens: *Hedera helix* (common ivy), *H. Algeriensis*, *H. arboreacens*, *H. argentea maculata*, *H. canariensis*, *H. chrysocarpa*, *H. digitata* (palmata), *H. donerailiensis*, *H. Hibernica*, and its variegated varieties; *H. lati-maculata*, *H. poetica*, *H. romana*, *H. variegata argentea*, *H. variegata aurea*, *H. variegata elegans*, *H. variegata tricolor*, *H. Roegneriana*. For a small but select lot of ivies, you cannot do better than take the following: Of green kinds, *Hedera donerailiensis minor*, *H. poetica*, *H. digitata*, *H. palmata*, *H. sagittifolia*; of variegated ones, *H. canariensis aureo-maculata*, *H. marginata argentea*, *H. minor marmorata*, *H. latifolia maculata*, *H. helix foliis aureis*, *H. rhombea*, *H. algeriensis variegata*, and *H. japonica*.

The next plants to which we have to call attention are the two hardy climbing *Aristolochias*, *sipho* and *tomentosa*. Here are two capital plants for bowers, or for covering any surface with fine and distinct leaves, which nobody is taking any notice of, compared to what they are worth. What is so fine for covering a bower, and running up a stake so as to form a pyramid of distinct foliage? One of the prettiest things we have ever seen was a tent or wigwam formed of *Aristolochia sipho*. In the first case, a number of long but useless branches were placed so as to form a framework, meeting at the top of course. Then *Aristolochia sipho* was planted all round, and soon it ran up to the top and formed a capital roof—a pleasanter wigwam you could scarcely see. *A. tomentosa* is quite a distinct species, and equally desirable with our old friend. Its leaves are of a yellowish tone, and slightly tomentose. It will prove capital as a deciduous covering for a bower of any kind, for forming pyramids in a varied garden, and for many other uses which will readily suggest themselves to the gardener who has once secured possession of this distinct plant.

There are some kinds of *Clematis* capital for bowers; notably the beautiful white *C. montana*, and the fragrant *C. flammula*. The last is a splendid thing to grow wild over old stumps, or on wild banks, &c., as it diffuses a most delicious odour over the garden in the late autumn; in fact, it is as valuable for this purpose at the end of the flowering season as the hawthorn is in May, or more so, for it flowers a long time. The common *Clematis*,

C. vitalba, often forms picturesque sheets of vegetation, drooping from trees, &c.; but it should, as a rule, be confined to the rougher parts of the garden. We have seen one or two very charming natural arbours formed from this, where it grew up oak or other trees, and then fell down in a mass. All that had to be done was to make an opening, and perhaps cut away a bit here and there. The new varieties of *Clematis* raised by Mr. Jackman are of course capital for the trellis; but they must not be associated with such things as *montana* or *flammula*, which would run over them; but, on the other hand, be reserved for the smaller and more select kind of trellis. On such they will prove very beautiful. The following is a list of kinds to be obtained in British nurseries, most of them worthy of a trial. Wirlings of some kind are so often desirable in gardens nowadays, that they will be found most acceptable to many. If instead of employing hedges, which require clipping often, we employed a covered trellis, how much more tasteful it would look, at least for the minor divisions of a garden!

Clematis azurea grandiflora, *C. campaniflora*, *C. elliptica*, *C. florida*, *C. f. flore-pleno* (warm wall), *C. f. Standishii*, *C. Francofurtensis*, *C. Fortunii*, *C. Hendersonii*, *C. insulensis*, *C. Jackmanii*, *C. lanuginosa*, *C. montana*, *C. nivea*, *C. patens Amelia*, *C. p. Helena*, *C. p. insignis*, *C. p. Louisa*, *C. p. monstrosa*, *C. p. Sophia*, *C. p. violacea*, *C. pubescens*, *C. rubro-violacea*, *C. Shillingii*, *C. Sieboldii*, *C. tubulosa*, *C. viticella*, *C. v. fl. alba*, *C. v. venosa*, *C. glauca*.

In covering bowers, it should be considered whether we wish them to be deciduous or not. Possibly, if they be near the house, it may be disagreeable to have them covered in winter. By using herbaceous plants which grow strongly in summer, and entirely sink under ground in winter, we may have pleasant shade and flowers in the summer, and not a vestige of naked or ragged vegetation in the winter; in fact, none at all. One of the best plants in existence for bowers of this class is *Convolvulus dahuricus*, a pink species, something like the common *convolvulus*—so much so, that many say it is the same—but it is larger and finer. There is also a white form of the same plant. They run up houses when trellised or trained, up railings, &c., beautifully. It is much better to put this plant in a position where it cannot ramble about, and become a weed. *Calystegia pubescens fl. pl.* may also be used in the same way. We know of nothing prettier on a railing than *Convolvulus dahuricus*. To leave the *Wiataria* to near the end of an article on bower plants, &c., is scarcely fair play. It is more often seen as a bower than as a wall plant; but may be used in almost any way. We have seen it trained to run from the ground up to trees on strong wires, but perhaps a more graceful use could not be made of it than to train it over a slender arch over a garden walk. So planted, it would flower later than the plants on the walls—an advantage. We cannot have this fine thing too long in bloom. The Scarlet Runner is also a wall as a bower plant. It is particularly useful, and so are other things we are now naming. It may in many cases be desirable to have a trellis-work covered way in a garden, this trellis-work to be covered with plants, and shady in summer, and quite bare and clear in winter. The Scarlet Runner is the very thing for all such positions; so too is *Asparagus Broussonetii*, a magnificent species not yet in cultivation. It runs about ten feet high, and dies quite down in summer. It would make a fine pillar plant. The following are also useful for the same purpose: *Cynanchum acutum* and *monspeliacum*, *Marsdenia erecta*; *Apocynum tuberosum*, *Tamus communis*, *Dioscorea batatas*, *Periploca græca*, *Hablitzia tannoides*, *Boussingaultia baselloides*, *Heladianthia dubia*, a quick-growing, pretty, climbing, cucurbitaceous plant, with an abundance of yellow flowers; and various annual plants, to be mentioned by and by. *Menispermum canadense* and *virginicum*, very good, they shine like ivy.

One magnificent set of climbing bower and wall plants are the *Cissuses*, near relatives of the Virginian Creeper. The following are the best, and these are of great merit: *Cissus orientalis*, *C. pubescens*, *Ampelopsis bipinnata*, *Bridgeaia spicata*.

Again we may begin a selection with *Jasminum revolutum* and common one, *Lonicera confusa*, *L. flava*, *L. japonica*, and *L. periclymenum*: warm wall for most of these. The common honeysuckle, one of the best plants in existence, *Roses* of many kinds, *Lycium europæum*.

Annual plants for trellis-work, &c., a selection: *Abronia umbellata*, *Adlumia cirrosa*, *Cobea acandens*, *Coloquinte vivace*, &c., *Cyclanthera pedata*, *Sweet Peas*, *Tropæolum* of kinds, *Maurandias* in varieties, *Loasa* in varieties, *Lophospermum*, *Petunias* for very dwarf trellises against walls, &c., *Scyphanthus elegans*, *Thunbergias* in warm parts only, *Gourds* and *Scarlet Runners*, and lastly, the best of all, the beautiful varied flowers of the new varieties of *Convolvulus major*, than which there is nothing better for a low trellis.

FORWARD HO!

REPORTS OF PROVINCIAL EXHIBITIONS.

We commonly receive during the summer and autumn a sufficient number of reports of exhibitions, cut from newspapers, to make two full numbers of the Magazine weekly without a line of original matter. To publish all that are sent is impossible, but our rule has always been not to publish any. The objections of greatest weight against transferring these reports to our columns are the following:—1. Having appeared already in the districts where alone they can be of any interest, it would be a misuse of our pages to give them place there. Local interest having been gratified, it would be absurd for us to repeat what everybody in the least degree interested has already become familiar with. 2. Newspaper reports on horticultural affairs are, as a rule, so badly done that we should commit ourselves to innumerable absurdities, untruths, and misrepresentations, were we to accept the favours and comply with the requests of our friends in respect of this matter. 3. Ninety-nine out of a hundred of all the reports of horticultural exhibitions that are published every season are to be relied upon for accuracy only so far as the secretaries have supplied to the reporters the names of the persons who have taken prizes. Now there can be no doubt that the names of prize-takers are proper to report, but in these pages something more is required, for our first business and bounden duty is to give the public information about plants, flowers, fruits, implements, and other matters of scientific importance, to which matters personal must have a secondary place.

It will be observed that our own reports invariably afford more or less information of a kind consistent with the primary objects of the Magazine. It is scarcely possible to overdo reporting when its legitimate objects are kept steadily in view. Through the reports published from time to time in these pages our readers are kept informed of the best species and varieties of

cultivated plants of all kinds, from the forest tree to the humblest fern, and every kind of climate, every variety of taste, every local necessity, contributes to our stock of useful knowledge. When original reports of provincial shows, prepared for the purpose and with a view to render them useful to horticulturists generally, when such reports as these reach us, they are always appropriated, and we are indebted to many good friends for assistance of this kind, and trust that the publication of what they send is evidence of its appreciation. Where there is loud profession of anxiety in behalf of a local exhibition, there might be, one would think, a little earnestness of work also. But, to speak plain, we really do not experience any startling sensation when we open a letter and find that the writer—all for the good of mankind—is burning with zeal in the interests of a provincial horticultural society, and offers no higher proof of it than a wearisome, dreariness, dull-drum report, half a dozen columns in length, cut from the "Mercury" or "Trumpet-blast" or "Slashing Independent" of the district. At all events, we follow a uniform rule with all such, and that is to drop them tenderly into the waste-basket; to do aught else with them is impossible, save and except that by reproducing them we might speedily make an end of the Magazine, for the public would never stand such an imposition. Anxious as ever to promote the interests of provincial exhibitions, convinced as ever that they are of far more importance to the life of the nation than all the great London exhibitions put together, well assured that they tend to the promotion of kindly feelings, and the removal of class prejudices in their several districts, and that they lead to an increase of the earth's best productions, and expand the mind of man to a better understanding of the ways of nature, we must nevertheless, and indeed for these very reasons, exercise some degree of circumspection as to reporting, and we are quite convinced that the systematic rejection of newspaper cuttings is absolutely essential, so long as we pretend to supply the public with original and useful information. Exceptions will of course occur. Not long since we appropriated instantly upon its receipt a newspaper report which possessed a value and interest rarely occurring; it had, in fact, by some strange and rare decree of fate, been prepared by a person who understood what he had to report upon. But in this case the correspondent who forwarded it took the pains to correct and improve it: the names of the plants were put right, a few particulars were added to adapt it to the pages of a work where it would remain for reference for an indefinite time to come, and it was as good as the best original report could be; and, in fact, if fifty competent persons had reported simultaneously the result in every case must have been nearly the same. It needs discretion to determine when this may be done and how it should be done. Our business more especially is to thank hundreds of good friends for what they send us, and to explain, as we have done, how it is that the endeavours of some appear not to be duly valued.

S. H.

Calendar.

WORK FOR WEEK COMMENCING SEPTEMBER 14.

Kitchen Garden and Frame Ground.

LETTUCES required for use in winter to be planted out, a portion in frames, and another portion on a warm sloping border. The cabbage kinds will bear frost with the least injury. Some forward plants of cosp put out now on a rich warm border will come into use late in the autumn.

ONIONS to be taken up when the weather is dry, and well ripened for storing. Those from autumn sowing will now want thinning, and the thinnings may be planted on a warm rich border to make large bulbs next season, or for use during winter.

PARSLEY sown in July to be thinned, and the thinnings planted if needful. Remove all the plants that show single leaves, and in transplanting save only those that show handsomely-curved leaves.

CAPSICUMS and TOMATOES may be gathered before they are ripe if needful, and ripened by laying them on a shelf in a warm greenhouse.

Flower Garden

ROSES budded this season require now to be looked over, the wild growth cut in slightly, the ties loosened, and any wild buds starting below the work to be rubbed off. Roses struck from cuttings to be potted off as soon as rooted, into 60-sized pots, and to be put on a gentle dung heat, to promote the filling of the pots with roots. Roses layered in the open ground may be removed and potted; in fact, it is better to winter all roses on their own roots in pots the first season after striking them, if there are conveniences for doing so.

BEDDING PLANTS struck in the open ground must be potted forthwith; in all cases a poor sandy soil and plenty of drainage must be used, especially if the plants are to be kept in pits or other places where they will be exposed to a low temperature during hard weather. Take up all choice plants now that it is intended to keep through the winter, and pot them; if left in the ground any longer they will be likely to die after potting.

BULBS of all kinds which it is inconvenient to plant early because of the ground being occupied, may be started in a mixture of leaf-mould and old dung, or in cocoa-nut waste, so as to be lifted in clumps with good roots to the positions in which they are to flower as soon as those positions are ready for them. When an early bloom of Snowdrops and Crocuses is required, and the ground cannot be made ready for the bulbs, this plan answers the purpose to perfection.

FLOWERING SHRUBS to be forced for the conservatory should now be thought of, to get them potted up and plunged ready to be taken in to force. Plants that have made good growth in the open ground are best for this work, such as Lilacs, Kalmias, Daphnes, Andromedas, Polygala chamæbuxus, Ledum latifolium, Rhodora canadense, double-flowering plums and cherries, Azaleas of the nudiflora section, Weigelas, &c. Get them into as small pots as possible without doing any serious harm to their roots, and plunge in a bed of cocoa-nut waste, in a sheltered position, till required to go to the forcing-house.

PLANTING may be proceeded with from this time to the end of November, beginning with evergreens, and getting them into their places, and meanwhile preparing the stations for deciduous trees, fruits, &c. Whenever it is possible to prepare the ground some time before planting, it should be done; and where orchards and shrubberies are to be planted in November the soil should now be trenched up and made ready, even to manuring if required. It is much against the prosperity of the trees to be planted in soil only recently turned over, and before there has been time for the atmosphere and sunshine to act upon it.

RANUNCULUSES ALL THE YEAR ROUND.—It is pretty well known that a deep moist loam, annually enriched with manure, and an open sunny position, are requisites in the culture of the ranunculus. Into such particulars we shall not now enter, but shall occupy a small space to say what perhaps has never been said before, that ranunculus may be had in bloom all the year round. It has often been observed that the roots may be kept in the drawer for two years, and then if planted will grow well. Reflecting upon this, and being admirers of these splendid flowers, we some years ago devised an experiment. We planted out of doors in October, February, March, April, May, June, July, August, and September. Unvarying success was not attained, but neither did we have any serious failure. Those planted in October and February bloomed in May and June; those planted in March and April bloomed in June and July; those planted in May and June bloomed in August and September; and those planted in July bloomed in October. There the out-door flowers ceased. But the succession was kept going by the use of frames and pits in this wise. Some roots were preserved in silver sand beyond the season of planting a year and a half; that is to say, fresh roots now on sale should be kept till 1868. A few of course will die, but that is no matter, they are cheap, and we can afford to lose them. In the month of August pot a large lot, and another lot plant in a bed in a frame. Keep the potted roots in frames until they have begun to grow freely, then remove them to the greenhouse a few at a time, and they will bloom beautifully in October and November; those in the frame coming in during December, January, and February. Beds of ranunculus are not usually planted till February, but there are many skillful growers who plant in autumn.

IXIA and SPARAXIS.—These have of late years become general favourites, and deservedly, for their graceful outlines and lovely colours are scarcely surpassed by any other class of flowers. They are nearly hardy, and will do well in a warm, sheltered, well-drained border, consisting of equal parts sandy peat, sandy loam, and leaf-mould, if planted six inches deep. When grown in pots, the protection of a frame is all they require, with abundance of water when growing freely. Greenhouse treatment is scarcely good for them; they become infested with vermin if kept too warm, but, on the other hand, they cannot endure much frost. Put three to five bulbs in a five or six inch pot, and let them be covered one inch with soil, so as to have as great a depth as possible for rooting. The following are lovely—IXIAS: *Bucephalus*, *Crateroides*, *Elvira*, *Golden Drop*, *Lady Slade*, *Pallas*, *Plantus*, *Titus*, *Brutus*, *Wonder*. SPARAXIS: *Emilius*, *Grandiflorus*, *Leopard*, *Maculata*, *Napoleon III.*, *Tricolor*, *Victor Emmanuel*. When planted in open borders in cold districts, it would be well to cover the beds with straw, or boughs of spruce, during frosty weather. In Jersey and the West of England they grow with great luxuriance in the open ground.

SIBERIAN SQUILL.—This lovely subject is well adapted for small beds and margins of large beds in the parterre. It is amenable to pot culture, but does not make much show unless seen in large mass. Any tolerably good sandy loam will suit it admirably, and, if planted among herbaceous plants, and left untouched for several years, it will contribute wonderfully to the beauty of the garden in the season of spring. The most distinct and beautiful varieties are *biflorus*, *siberica*, *campanulata*, *campanulata alba*, and *Belgica*.

BULBS FOR CHOICE BORDERS.—*Triteleja uniflora* is a lovely gem, quite hardy; it blooms in April, the flowers are white, with a band of pale blue on each segment, and emit an agreeable perfume. As it is a native of South America, the patches should be marked to facilitate the placing of some slight protection over them during very severe weather; or, better still, put a cone of coal-ashes over each clump when planted, and remove this in February. *Bulbocodium vernum*, planted on the margins of beds, between rows of crocuses, produces a charming display of rosy pink flowers early in the year. It is as hardy as chickweed. *Colchicum autumnale* ought to be in every garden, in spots not likely to be disturbed, as its lovely flowers appear in the decline of the season, when dark days and long nights begin to make an end of most other flowers. The winter aconite, *Eranthis hyemalis*, is an exquisite gem for beds and borders, producing pale yellow flowers, close to the ground, in January and February. A good clump of it gives the idea of a golden pavement such as Dick Whittington dreamt about.

Fruit Garden and Orchard House.

ORCHARD HOUSE TREES to have small supplies of water, and full exposure to the sun, near a wall or fence facing south, where the heat will be reflected on them, and they will ripen their wood well. Any trees that are in a green and sappy state may be laid on their sides and be sprinkled over their tops every morning. This will check growth without distressing them, and help to coax them into rest. Get ready for repotting, planting out any that are to be turned out of the house, &c., as when November comes there will be extra pressure of work, and many important jobs of planting and potting may be delayed to the injury of next season's produce, unless pots, compost, &c., are got ready in good time. All fruit-trees that were forced, especially cherries, peaches, and nectarines, should now be quite at rest, and leafless. To make an end of their season, shake the remaining leaves off, and give them their winter pruning, and repot any that require it. Those not repotted to have the top soil of the pots removed, and its place supplied with fresh turfy soil and rotten dung heaped up round the stem of the tree.

Greenhouse and Conservatory.

CINERARIAS, PRIMULAS, CALCEOLARIAS of the herbaceous class, and other soft-wooded plants now growing freely, should be carefully looked over to see that they are in a fit state for housing as required. Some will want a shift; some will be found infested with fly, &c. None of these things should suffer for want of water, as it will spoil their looks by causing the leaves to turn yellow.

FUCHSIAS may be kept in bloom late by the aid of weak manure-water and a close warm house. The shading may be removed and the pots have a sprinkling of fresh sheep or deer dung as a top dressing. Gather ripe berries of any varieties from which seed is required; bruise the berries with sand, and expose the mixture of pulp and sand to the sun till quite dry; then store it in chip boxes till spring, when sow said and seeds together. Raisers of seedlings who can keep the young plants in the stove all winter may sow at once in a mixture of three parts leaf and one of sandy loam, and start in a gentle heat.

HARD-WOODED PLANTS must be kept well aired, and in full sunshine, to ripen the wood and give them full strength to pass the winter in an ordinary greenhouse temperature. Heath, Epacris, Pimelia, &c., to have free ventilation, and the rank shoots pinched in, to preserve uniformity of growth.

Stove and Orchid House.

Orchids generally should have less moisture as the days shorten. The majority of growers keep them too damp and too warm all winter, but they should now be prepared to pass the winter at as low a temperature as will be safe, and in as dormant a state as possible. Fires will be useful now on dull days to dry the house, and allow of the admission of air. Young plants of *Aeides*, *Dendrobium*, *Vanda*, *Cattleya*, and *Saccolabium* to be kept growing in the warmest compartment.

ORCHID-GROWING MADE EASY.—It is now generally understood that large and expensive houses are not required for the cultivation of orchids. Even in the midst of densely-crowded cities, men who take an interest in their growth have found that they could be grown in little glass houses thrown out from the second floor over passages, or any similarly unlikely places. In Wardian cases, on a scale slightly enlarged, these plants have found a genial home. They require hardly more attention than that required to keep a collection of ferns in good health. A little heat, derived from a diverted kitchen flue or a hot-water pipe, will supply all they require in this way. Moisture is always at command; and, as regards the general treatment, the cultivator who can grow ferns to his own satisfaction would succeed equally well with regard to orchids. First of all, we ought to say a few words about the buying of the plants. As their price will in a great measure depend upon their size, we would recommend that little bits, well established, be first purchased. It is better to have little pieces of two or three species rather than a large specimen of one. The pleasure of watching their growth is thus increased. At the same time it would be advisable to ascertain what kind of treatment the plants purchased have been previously subjected to; if they have been grown in a stove, be careful that they get "hardened" gradually before being placed in a greenhouse. Sudden changes of temperature and of treatment are dangerous for any plants, but orchids more particularly. As to the house, if a new one is to be built, let it be small, span-roofed, and sunk below ground. Plants never succeed so well as in houses of this description. Our idea of a perfect house for orchids would be one in order to enter which it would be necessary to descend some four or five steps below the level of the ground. In such a place less heat is necessary to keep out the frost, moisture in the atmosphere can be more easily secured, the expense of building is much less, and the plants succeed much more to one's satisfaction; they seem to be more at home in such a place. With a little practice, it is easy to see if a plant feels itself "at home," though it is very difficult to convey one's meaning in words. The yellowish tint or the turned point of a leaf are sufficient to point out to the attentive eye the fact that something is wrong; and more trivial points than these attract his attention—he can hardly tell how or why. It must not be supposed, from what we have said, that a house built on this plan is the only place in which orchids can be grown. If your little house be facing the north, so much the better; if not, you must shade it well, and the best way of doing this is by tacking tiffany or some thin material on the outside of the lights and roof, so that it may remain during summer without the constant attention required by a movable shade. There is yet another point we would urge, not only upon amateurs, but also upon professional gardeners. Plants do not like bare surfaces of whitewashed wall or carefully cleaned shelves of wood or stone. They have a perfect abhorrence of light and heat-reflecting surfaces behind or beneath their foliage. Cover your walls with some close-growing climber, and for this purpose nothing is better than the neat *Ficus repens*; and *Selaginella denticulata* may be grown in very shallow soil, sand, cocoa-nut fibre, or any other substance upon which the pots may be placed; it will look pleasant, may be kept within bounds by clipping, which it will bear to any extent, and will be much more beneficial for the plants than any plain surface. Orchids may be naturally divided into two sections, the terrestrial and the epiphytal, or, in other words, those which naturally grow in soil and those which grow upon the branches of trees. But the latter as well as the former may, as a rule, be grown in pots. Still, as is the case with all other rules, there are exceptions to this; but those exceptions will hardly fall in the way of beginners. In horticulture it is a mistake to think that we may always succeed by following nature—we are obliged to follow her under such artificial circumstances. The pots should always be well drained; one-third, or even half, the pot should be filled with broken potsherds. Why not use shallower pots and less drainage? you may naturally ask. The reason is this, that the roots seem to enjoy getting down into the spaces between the corks, and obtain all they require there for the sustenance of the plant. The soil should consist of chopped sphagnum (previously soaked in boiling water, to destroy insects, and then partially dried again) and the fibrous part of good peat, which has been so well beaten that the earthy part has been sifted out. Be careful not to retain any half-dead rhizomes of the common brake, so common in peat, or they may lead to the growth of fungi injurious to the orchid. With this compost mix a little good gritty white sand. In potting your plants, cover the drainage with the mixture above mentioned, and nearly up to the level of the rim of the pot; then spread out the roots of the plant which you have carefully removed from its old home, put a little more of the soil about them, and make all firm. This latter is a very important point; if the plant be loose, and able to shake about, you may be certain it will not succeed. This can be obviated by a stick or two, or a few pegs; but be careful in the use of these not to injure the roots. In the absence of, or as a substitute for, peat, cocoa-nut fibre has been recommended for orchid culture, and in cases where a nourishing soil is not absolutely necessary it answers perfectly. A warm greenhouse is rather a vague term to use; we had better say that the temperature in winter might, during daytime, rise to 55° or 60°, and should not drop much below 50° at night, though a few degrees colder would probably do no harm. In summer, guard against too great heat. Shading we have already recommended. Moisture must be attended to all the year round; the atmosphere of the house must not be allowed to become quite dry, even in winter; while during the season of growth the air should be kept very moist. This may be done by wetting the walls, paths, and stages of the house. This is a much safer plan for the beginner than syringing the plants themselves, which we should not recommend when they are making their young growth. Water should never be allowed to fall upon the flowers; it is sure to make them decay prematurely. Several kinds may with perfect safety be removed to the dwelling-room while in flower, and would remain longer in bloom than in a moist and warm house. With the good drainage we have recommended, they may be watered freely during the season of growth, and as the newly-formed bulbs attain their full size the supply should be gradually reduced. When perfectly at rest, they should not be allowed to become quite dry, but very

nearly so; or, to put it in plainer words, the hand should be able to detect a slight moisture if laid upon the soil. As the soil will be above the level of the rim of the pot, the plants should be slowly watered, and care should be taken that all parts of the soil are moistened. Although the soil will be porous, yet in careless hands one side of the plant may be kept moist while the back is dry, and of course this injures a part of the roots. The orchid-house is not without its pests. Slugs are a great nuisance, for they are very fond of the young roots. These as well as woodlice are easily entrapped. Cockroaches in some localities abound, but phosphor-paste, or Chace's beetle-poison (which should be used with care) will keep them in check. After putting it down for a few nights, it should be discontinued for a time, and then put down once more—a little piece about the size of a bean being put in the several places where they have been noticed. Put it on a piece of crock, which can be put out of the way in the morning. Thrips and green-fly may make their appearance occasionally. Keep a sharp look-out for them, and as soon as an infested plant is noticed, turn it on its side on a mat or the turf, and syringe it. This will, as a general rule, be sufficient; but if not, fumigating with tobacco must be resorted to. Woodlice and shell-snails may be trapped by putting turnips or potatoes in halves, and scooping out the insides. Place these, hollow side downwards, in spots near where the vermin harbour and examine them every morning, and destroy the victims caught. The following list of plants, which may be obtained at very moderate prices, and are suitable for the amateur who is commencing their cultivation, may be found useful: *Anguloa Clovesiana*, *Acrides Lindleyana*, *A. Warneri*, *Barkeria Skinnerii*, *B. spectabilis*, *Brassavola glauca*, *Cattleya labiata*, *C. Mossii*, *C. Skinneri*, *Chysis bracteata*, *Cypripedium insigne*, *C. barbatum*, *Cælogyne cristata*, *C. flaccida*, and any other species; *Dendrobium chrysanthemum*, *D. Kingianum*, *D. speciosum*, *D. nobile*, and others; *Disa grandiflora*, *Epidendrum macrochilum*, *E. Stamfordianum*, *E. vitellinum*, *Leptotes bicolor*, *Lælia superbiens*, *L. anceps*, *L. purpurata*, *Lycaste Skinneri*, *L. aromatica*, *L. Deppei*, *Miltonia spectabilis*, *M. candida*, *M. Moreletiana*, *Odontoglossum grande*, *O. Uroskinneri*, and many other kinds; *Oncidium Papilio*, *O. ampliatum*, and varieties; *Pleione lagenaria*, *P. maculata*, *P. Wallichii*, *Trichopilia tortilis*.

Forcing Pit.

PINES.—Repot the young stock struck during the summer, and plunge in a brisk heat; suckers on old stools to be taken off and potted singly, and plunged at once; they will root immediately. Give as much air as possible during fine weather.

NOTES ON STRAWBERRIES, NEW AND OLD.

Although strawberries have been cultivated for the London market for many centuries, the greatest impetus to an advancement of the type dates from the beginning of the present century—may, it might even be confined to the boyhood of men who are now in the prime of life. To show, however, that both strawberries and cherries were a marketable commodity so far back as 1480, we give one of Lidgate's stanzas of a poem called the "London Lyckpenny"—

Then unto London I dyde me hye,
Of all the land it bearyeth the pryse;
"Gode pescode," one began to cry,
"Strawberry rype, and cherrys in the ryse."

The common wood strawberry (*Fragaria vesca*) is, in the opinion of some, one of the parents of the now numerous race. An interfusion of blood of the alpine variety, of the Cbill and Hautbois of Bohemia, together with the "old scarlet" of North America, and their combined progeny has almost set at defiance the classification given, we think, by Mr. Keen, of Isleworth, in the "Horticultural Transactions," and generally adopted at the time. The division was "scarlet, black, pine, hautbois, green, alpine, and wood." That same Mr. Keen was the raiser of many admirable varieties, which took and maintained a leading position up to almost the present day. His "Keer's Seedling" is probably more grown now than any other, and is looked to as a good palatable free-bearing sort, which serves the double purpose of dessert and preserving. We owe, probably, more, however, to the pine strawberry of Louisiana and Virginia than to any other for that briskness of aroma, which, withal, is so delightful and stimulating, and without which no fruit is held in high estimation.

In classifying a list now, we would look more to the prolonging of the season, the quality and size of berry, to the habit and hardness of the plant, to its flowering properties, and how they would be affected by sudden vicissitudes, than to the mere colour of the berry. In endeavouring to cater towards that end cross-breeders have sunk that little bit of technical colour distinction, and if black and red and white get mixed together by natural interfusion, like so many colours on the palette of an artist, no matter. It is no advantage to an amateur grower, and very little indeed to our great gardeners, to grow a numerous family. Numbers of varieties are often tantalizing, being of little practical use to most growers, and only admissible where a thorough system of testing is organized. To test strawberries well, they should be grown on an exposed quarter of ground well trenched and manured, and not on those little narrow wall borders, which often neither present surface nor subsoil sufficient for a fair test to be taken; and yet we often hear both amateurs and gardeners, upon the faith of incomplete, partial, and therefore anything but satisfactory evidence, calling out loudly either for this or against that sort. No plant repays first-rate cultivation better than the strawberry, and if any of our readers doubt it, pray, first opportunity, ask any of the great market gardeners around London, and they will tell them of the advantage of deep tillage and good manure.

All things considered, we must still give place to two of our oldest favourites, Keen's Seedling and British Queen. The former is invaluable as a grower, a bearer, and a general fruit for the great list of those who possess cottage and villa gardens. The latter is a little more tender, requires a good climate, and, if it can be had, a better loamy soil, incorporated with grit. If that be come-at-able, it is a noble sort, having all the qualities to be desired in this kind of fruit but colour. Under the best culture it is deficient in this point, and although it now has a few rivals, such for example as John Powell and Crimson Queen, we would not displace it from its high position. In some localities this latter may be had equal in flavour to British Queen, but not generally so; it undoubtedly is its equal in size, and its superior in point of colour.

President is a noble fruit, free in form, excellent in colour, very free and hardy, and will always rank high in point of appearance. It does not

possess the flavour of Osear or Sir Harry, but it is one, notwithstanding, that ought to be generally grown. Sir Harry has been much abused, and Mr. Underhill, if he sent out a spurious variety along with it, has something to answer for. The true variety is of very hardy constitution, withstanding the cold of May better than most of its compeers, and is a good average cropper, with berries of fully average size and of very good flavour. The Lady has not been sufficiently tried, but we doubt, from our experience of it, if it is a match for Sir Harry. Marguerite is a very desirable sort—a very excellent forcer and a good free bearer; when dished looks tempting, and when tried is not disappointing to even critical palates. Sir Joseph Paxton is also first-rate, somewhat after the character of President, but not so large. Dr. Hogg is very much allied to Crimson Queen, possessing a most excellent flavour. If there be a sufficient distinction, which another year's growth will sufficiently prove, it will be one of the best of modern introductions. La Constante comes generally good, is a very late sort, and yet offers to be a good forcer. Its habit is one of the best, and might be looked upon as a model in that respect, being bushy and dwarf, yielding large, fine coloured, and finely formed fruit in abundance. In some of the colder localities the bloom was partially destroyed under the influence of a by no means auspicious spring and opening summer; but we look upon this in an ordinary season with great confidence.

As a preserving strawberry, Black Prince has been often used; but we have now a far better one in Ingram's Prince of Wales. It shows a moderately sized berry of the best colour, and possesses a fine piquant flavour. It is an object with those well up in preserving this fine fruit to keep the berries entire, and if they can be had as nearly uniform in size as possible so much the better. No preserve is more difficult to make to satisfy the eye and the palate than this, and the first-class housekeeper prides herself in these two things—preserving them to appear whole, and of a rich ruby transparent colour.—*The Farmer.*

Replies to Queries.

Diseased Vines.—I beg to enclose for your inspection a sample of my grapes in their present state, asking your advice and counsel, so as, if possible, to remedy the state of things at present existing. It may be well to state that the vines are planted on a border turfed over; they are six years old, and this is the second year of bearing; they have this year an average crop. The house in which they are fruiting is surrounded by trees, so that the sun does not get at them till the middle of the day; and there is a thorough draught through the house, but no upward ventilation. A moat surrounds the grounds at a short distance from the house. If you can possibly advise me what to do—whether to cut down the trees, or alter the draught through the house, or remove the turf from the border, for it seems a pity to lose an otherwise good crop of grapes. E. H. A.

[This is a case of shanking, and we can hold out no hopes at all that the crop can be saved, nor can much be done just now for the benefit of the vines. It is simply a marvellous thing that any one should expect ripe grapes under such circumstances as detailed above, and we print the letter, not to vex the writer (for we have suppressed the name) but as a warning to all whom it may concern. The vines are injured at the roots by the grass-turf, which screens off rain and sun; injured above by cold draughts and shade; all the elements of success are absent, therefore it is simply a marvel that they produce grapes at all. It follows, however, from the fact that there is a crop to care about, that these vines may be made healthy and fruitful with but little trouble. Two things are essential to their future well-doing—the trees must be cut down sufficiently to admit the sun freely to the house and to the border, the whole of the time it is above the horizon, and the turf must be removed from the border to give the roots the benefit of sun and air. These two improvements might suffice, but we would suggest two more. Let the border be lightly forked over to break the surface, but with care not to injure the roots, and then lay on it six inches depth of long dung in a rather green state, say half rotten. During the winter this will rot down to a kindly mulch. But four inches of quite rotten manure will do. Next check the draught through the house, and make a top ventilator, or leave all alone till the middle of May next, and then break a few squares of glass in the roof. Vines require regular and moderate ventilation; a rush of air is bad principally because it reduces the temperature, and to be quite closely shut up is equally injurious.]

Acer negundo variegata.—Having noticed lately several allusions to this shrub as a decorative object, I should like to know whether you consider it to be hardy? I have made two attempts to transplant standards obtained from a nursery in the autumn and spring, both of which proved unsuccessful; perhaps they succeed better as dwarf shrubs. Will you give me the benefit of your advice on the matter? I may observe that the soil is sandy with a sub-soil of chalk; so there is no lack of drainage. The situation open to north and west. BIRD'S EYE MAPLE.

Old Charlton.
[The variegated *Acer negundo* is hardy in the most proper acceptation of the term, yet in certain positions and climates it may be susceptible of injury by frost. In a country where hollies, pinuses, cedars, bays, laurels, and araucarias are sometimes destroyed by frost, we may expect any variegated-leaved tree to suffer occasionally. We can point to one fine standard of this variety which for seven years has stood all the assaults of hard weather, on a spot where deodaras have been twice nearly destroyed, and where last winter a fine tree of *Abies morinda*, standing within a few yards only of the acer, was killed root and branch. Have any of our readers anywhere found this tree other than hardy?]

T. R.—Chate's book on Cannas is published by E. Donnaud, 9, Rue Casette, Paris; the price 1½ fr. The subject you refer to will have attention in due time; the writer to whom you refer is not now in this country.

Messrs. Barr and Sugden.—The cucumber is a handsome white-spined variety, beautiful to look at, and the flesh finely textured. The sample sent measured exactly 25 inches, exceedingly short in the neck, quite regular in diameter throughout; a finer fruit could not be desired.

Messrs. Dillistone and Woodthorpe.—The herbaceous *Lobelia* is a noble spike of brilliant scarlet-crimson flowers; the petals wider than the average of the best varieties in cultivation. The stem is a deep purple colour, and the leaves a bronzy tone of dark green. Decidedly an acquisition, and well adapted to revive a taste for this easily-grown and effective race of garden flowers.

C. W.—What they say about the authority you quote may serve for the moment some trade purpose, but it raises the question about amateur *versus* practical; and it may happen sometimes that the first is the best practical of the two. We should like to communicate with you on this subject privately, and with a view to gratify your desire. If the proposal suits you, send your name and address. The general question shall have attention soon.

Propagating Variegated Arabis.—Short and Sweet.—Now is the best time in the whole year to propagate all kinds of dwarf tufted herbaceous plants that may be parted at the roots, such as arabis, polyanthus, primroses, &c. Take them up, divide into as many pieces or tufts as can be conveniently done, with a bit of root to each, and plant again. On all comparatively dry soils, in nearly every part of Great Britain, the variegated arabis is quite hardy, and never need be wintered under glass at all. But in some damp soils, especially in humid valleys, it is apt to die off in winter. In such a case, the best way to increase the stock would be to take up the plant at once, divide freely, and plant the pieces pretty thick in pots or boxes, with plenty of drainage and poor sandy soil, and winter in frames, pits, or airy greenhouses, giving very little water all through the winter. Very much of this plant is propagated at nurseries in a brisk heat in spring, when the little tufts may be seen rooting and flowering at the same time, and every mit with a bit of stem and a tuft of leaves soon makes a plant in a soil consisting almost wholly of sand, and with a very small allowance of water. But the easiest method is to do it now, as the tufts will make new roots long before frosty weather occurs. Hundreds of hardy plants of the borders may be treated in the same way, and where the roots cannot be parted, cuttings will do as well.

Roses out of Health.—Rose Lover.—From the size of the leaves, we conclude that your soil is good, and that you are in a fair way to do well with roses. The sample of leaves sent is almost entirely eaten up by an insect pest, the thrip (*Thrips adonidum*), a small insect with dirty white wings and rust-coloured body. This insect attacks plants out of doors only during hot dry weather, and the best preventive against it is water in some form or other. The free use of the garden engine or a "Niagara" hand-pump as soon as dry weather sets in, with occasional liberal waterings of the roses at the roots (the more needful, possibly, as yours is a limestone soil), would probably prevent this pest making any head-way. Water is the more needful in this case, too, to wash off the black deposit which the thrip makes, and with which the leaves sent are thickly covered. Should the thrip ever again get ahead of you, in spite of the frequent wetting or the leaves by the water engine, try Scotch snuff, powdered by means of a dredger on the under sides of the leaves. This is a tedious but effectual process, as the thrip cannot feed where the snuff adheres. Equally simple and effective, and costing less time in use, is the "Aphis wash" of the City Soap Company. This has to be diluted with water, and applied either by dipping the shoots in the solution, or by means of the syringe; we prefer to dip, so far as that is possible.

CATALOGUES.

WILLIAM PAUL, WALTHAM CROSS.—*Select List of Hyacinths, Early Tulips, &c.* On the usual plan and in the lists of hyacinths comprising several important novelties.

SMITH AND SIMONS, BUCHANAN STREET, GLASGOW.—*Dutch Root List, 1867.* This contains, in addition to the usual lists of hyacinths, tulips, crocuses, &c., a capital selection of gladioli.

Correspondence.

AERIAL ROOTS ON A GERANIUM.—Perhaps the enclosed may interest some of your readers. I have a geranium (*Rose Rendatler*) which threw a side shoot from the main stem, which, apparently not getting sufficient to

live on, determined to seek for itself (what a glorious lesson for a young beginner!) in the following manner. If the above is a common occurrence, of course you will not lose any time about it, but commit it to the waste basket. J. P.

[Not at all common.]

A VEGETABLE POEM.—A poetical young gardener, somewhere in the South, while despondent from the effects of the late unseasonable weather, gets off the following mellifluous strains:—

Onion garden bed reclining,
Beets a youth his aching head;
"Cauliflowers be! weeds confront me;
Lettuce hence," he sadly said.
"Carrots out the stoutest manhood,
Peas my weary soul doth need;
Bean O! strife for me hereafter,
Else my art will go to seed."

Pronounced thus:—

On yon garden bed reclining,
Beets a youth his aching head;
"Oull I flowers, low weeds confront me;
Let us hence," he sadly said.
"Carrots out the stoutest manhood,
Pease my weary soul doth need;
Be no strife for me hereafter,
Else my heart will go to seed."

The Gardener's Magazine.

SATURDAY, SEPTEMBER 21, 1867.

THE CORDON SYSTEM OF TRAINING FRUIT-TREES is at once the most artistic in appearance and the most certainly fruitful of any method known, when it is carried out in its integrity. One of its special advantages is that the trees assume any form desired by the cultivator, quite covering, by the most severe symmetry, a breadth of wall, or trellis, forming, if needful, single lines dotted with tufts of leaves and fruits when trained on wires, or presenting goblet-shaped trees in the open quarters, the form of the goblet being indicated by a series of rods beset with leaves and fruit, without a single side branch or lateral. This system is very much practised in France, where, indeed, every possible system of training fruit-trees is carried to the utmost possible perfection; and it has been much recommended of late for adoption in English gardens, the advocates of its adoption averring that the deficiencies of our home supplies of fruit may be amended by the practice of the cordon system. Many of our readers have asked for some information on the cordon system and its claims to the favour of English fruit-growers, and we gladly embrace the present opportunity of offering a few general observations, premising that very much more may be said upon the subject than we have any idea of saying now. What is a cordon? It is in this connexion a tree trained so that its branches shall bear

examples of simple cordon peach-trees, with the mode of filling up at each end, to occupy profitably the whole space of the wall. In the case of the peach, a succession of fruit-branches is kept up to replace those that have fruited by a process analogous to the long-rod system of grape-growing, but which has the advantage of greater certainty.

The question arises, Shall we encourage the cordon system in English gardens? It is not without deliberation that we answer "No." There are many things that are good in France that it is not desirable for us to imitate. Undoubtedly the cordon system is sound, and when fairly carried out satisfactory. There are miles of good walls in this country on which cordon trees might be trained with advantage. Nevertheless, we feel satisfied that this system will never become popular in this country, and, moreover, we venture to say that it is by no means desirable to press it over-earnestly upon the attention of English cultivators, for it is certain that in many instances it must lead to disappointment. There is one good reason for objecting to it here, that our autumns are not ordinarily of a sufficiently decisive character, and, as a rule, are too moist and too cold for it. A tree that has had a series of checks all the summer will be, even if pinching be discontinued at the proper time, in a soft condition, and inclined to grow when it should be inclined to rest. The system of "long-pruning," described in the GARDENER'S MAGAZINE of October 14, 1865, is far more likely to result in a plentiful production of fruit in a precarious climate than any kind of pinching; and, at all events, if we cannot make pretty sure of good

Fig. 1.

Fig. 2.

some resemblance to a knotted rope. Two things amongst many are essential to the production of a cordon—a free growth of the shoot or rod to augment its length as needful, and a constant pinching in of all side branches, so as to convert them into short fruit-spurs. The most favourite form of cordon is the one represented in the annexed figures. This is called the "oblique cordon," and is applicable to every kind of fruit that can be grown on a wall, but is most especially adapted for peaches and pears. In forming such cordons the young trees are planted about three feet apart, and are from the first inclined at an angle of 60°. They are cut down to within two or three buds of the base, and the shoots from these buds are trained as required, and encouraged to attain the utmost length. No lateral shoots are allowed; to prevent them, disbudding, green pruning, and pinching are regularly performed, and if the wood ripens well in the autumn clusters of fruit-buds are formed the whole length, or greater part of the whole length, of the rod. At the next pruning about a third of the length of every rod is cut away, and again the terminal bud is encouraged to grow freely. Thus the wall or trellis is quickly covered with fruitful wood, and every fruit is in its proper place, every leaf is developed according to system. The trees are brought so completely under the control of the cultivator, that they may be said to be, in more than an ordinary sense, of the term, the creations of his own mind. In figure 1 we have the winter aspect of a series of oblique cordon pears. A tree at each end is shown with several branches to indicate the mode of filling up the angles of walls devoted to trees of this kind. The two trees in the centre are kept to two rods each, being grafted low, and in the first instance closely cut back for the purpose. In figure 2 we have

ripening weather for the much pinched, pruned, and disbudded tree, it is preferable to allow it to grow freely in the early part of the season, with a view to affording it a long term for maturation of the season's growth. This climate is certainly not well adapted for cordon training of fruit-trees, and we advise such of our readers as may have been influenced by the articles in advocacy of the system which have lately appeared in the *Times*, to enter upon the experiment with caution, and not to invest in it to any great extent until they have acquired some experience.

But there is another reason why this system is never likely to gain favour here. There are very few Englishmen to be found who will follow with mechanical and unwearied pertinacity the tedious operations necessary to its full development. A French amateur will bestow as much time daily on one tree as would suffice an English amateur to take moderate care of fifty. We appeal to our Gallic as to our English readers, that this is the case; we have not the patience, the delicacy of manipulation, the love of minutiae of our neighbours. Here and there, in remote parts of the country, we may find a few clergymen, retired military and naval officers, and other gentlemen who live at home at ease, for whom the cordon system may have many attractions; but the thousands of busy men who turn to their gardens for recreation in the intervals of commercial hurry and anxiety, would soon be sickened by the exigent demands of cordon trees, if they once began their cultivation, and our advice to all such is, Do not begin; leave our brave allies to the enjoyment of such fancy work, and be assured that though they succeed in it, nine-tenths of all English practitioners would fail.

We are glad to see that, in the midst of much that was un-

intelligible in the *Times* discussion, Mr. J. R. Scott, who knows as much about practical fruit-growing as any other amateur in the country, has directed attention to the superior claims of dwarf pyramid and bush fruit-trees for English gardens, a subject on which we have expressed ourselves so freely and frequently that we have nothing more now to say than to express our belief that grafting low down, and as near to the roots as possible, and subsequent periodical lifting and careful root-pruning will promote early fruitfulness with free stocks, and that therefore there is not so much need for the quince, the doucin, and the mahaleb stocks, as many have been led to believe by a superfluity of persuasions. Whatever tends to promote an increased production of wholesome fruits in English gardens is to be accepted with gladness by wise men, and a discussion about first principles now and then may be good. But what we have heard respecting the cordon system lately has inclined us the more strongly to reject it, except under such peculiar circumstances as we have suggested as favourable for its adoption and final success.

THE minor daily papers are imitating the leading journal in getting up discussions on rural affairs. The *Daily Telegraph* reveals to us the fact that the walnut-tree produces valuable timber, and occasionally large supplies of marketable fruit, and suggests the planting of orchard-trees in hedge-rows everywhere. It would be very nice, no doubt, to inhale the perfume which would fill a country lane for hours after a wain had passed and brushed against the leaves of the walnut-trees, and agreeable to reflect upon the price of the ripe nuts coming down from its present average of a shilling to a penny for ten. But would there not be considerable risk of the village boys forsaking blackberries to climb for walnuts, and the occasional and accidental tearing down of branches for the fruit? The fact is, any better fruit than crabs and blackberries in English hedge-rows would do incalculable mischief, and whoever knows anything at all of the country would deplore seeing fruit-trees of any value planted there at present.

WORKING MEN'S FLOWER SHOW, STRATFORD.

The exhibition held by the working men of Stratford last year having proved eminently successful, the committee of the Working Men's Hall determined to venture on another, with a view of stirring up the floral enthusiasm of the working men of the district, and at the same time possibly realizing some profit by the undertaking for the benefit of the building fund. The exhibition took place at the hall on Wednesday and Thursday, the 11th and 12th inst. Plants were contributed scantily, but there was an abundance of fruits and cut flowers. Strange to say, dahlias were scarce. Some good groups of plants were put up by Mr. J. Harbott, of Chapel Street. Another and very fine group of plants was supplied by Messrs. Bunney, nurserymen, of Stratford. In this group we noticed fine examples of *Adiantum euneatum*, *A. trapeziforme*, *Cycas revoluta*, several *Caladiums*, a collection of *Amaryllis* in bloom, several *Yuccas*, &c., &c. The first prize for a collection of plants in the competitive classes was awarded to T. F. Buxton, Esq. (gardener, Mr. Marsden). In this group there were beautiful specimens of *Begonias*, *Ferns*, *Dracenas*, and other effective subjects. Second, J. Evans, Esq. (gardener, Mr. Edwards). In this collection some fine plants of *Haresfoot fern*, *Davallia canariensis*, growing on blocks of mulberry-tree wood. First for plants in bloom, Mr. Shipman, of West Ham. No second prize awarded. Third, Mr. Shippert, of West Ham. Twelve *verbenas*, first, S. Seadbrook, Esq. (gardener, Mr. Pool). From the same the best French and German *Asters*. Mr. Shipman presented a pretty group of *pompon Dahlias*. Mr. D. Western and Mr. J. Harbott contributed the best miscellaneous plants. Good *Fuchsias* from Mr. Wheeler, florist, Mr. T. Norton, and S. Seadbrook, Esq. An interesting novelty was contributed by Mr. Edwards, gardener to J. Evans, Esq.; this was a union *fuchsia* with a straight stem, on which were grafted three different varieties, namely, *Queen Elizabeth*, *Sir Colin Campbell*, and *Princess of Prussia*, the grafts being about a foot apart. The whole plant was well in flower, and was highly commended as a novelty.

Fruits were plentiful, and the collections shown by amateurs were highly creditable to them. The best general collection came from Mr. Winter, nurseryman, of West Ham; second, Mr. Hicks, gardener to — Loughton, Esq.; third, Mr. Shipman. In these collections there were good peaches, pears, apples, &c. Grapes and gourds were admirably shown by J. Evans, Esq., S. Seadbrook, Esq., and — Wagner, Esq. Mr. Evans contributed two brace of Stratford Hero cucumber; they were large and coarse.

TOWER HAMLETS FLORICULTURAL SOCIETY.

The autumn exhibition of this society was held at the "Royal Victor," Old Ford Road, on the 9th and 10th ult. Dahlias and *asters* were abundant and fine, and many miscellaneous subjects of high character were brought forward. In the open class for cut blooms of *asters*, a silver cup was offered in addition to other prizes. The cup was won by Mr. J. Fenn; second, Mr. Capps; third, Mr. F. Smith; fourth, Mr. Dracey. In the class for 12 cut blooms of *asters* there was a capital display; the names of the winners and the order in which they were placed were as follows: Messrs. J. Fenn, Capps, Cousins, Viles, Bangs, R. Fisher, Ball. In the class for 12 dahlias, first, Mr. J. Fenn, with *Lord Derby*, *Scarlet Gem*, *Miss Roberts*, and others; second, Mr. Walker, sen., with a very fine lot for a second place; third, Mr. T. Walker; fourth, Mr. W. Walker, jun.; fifth, Mr. Viles; sixth, Mr. Treadall; seventh, Mr. R. Fisher; eighth, Mr. Cormick. In the class for 6 the flowers were more uniformly good than in the foregoing; the successful exhibitors were Messrs. J. Fenn, R. Fisher, Walker, jun., T. Walker, Ball, Cormick.

Collections of plants were contributed by several persons. Mr. Capps took a first place for a collection of 100, comprising examples of *cactus*, *aloes*, *yuccas*, *sedums*, &c.; second, Mr. Viles; third, Mr. Warren; fourth, Mr. W. Hall. A fine collection, not for competition, was presented by Mr. Baynter. Mr. Capps took first place again in the class for three miscellaneous; in this group were beautiful examples of *Aloe frutescens* and

Opuntia leucotriche; second, Mr. Spillman; third, Mr. Viles; fourth, Mr. J. Fenn. The best *fuchsias* of any age came from Mr. Spillman; second, Mr. Ball. Spring-struck *fuchsias* were best shown by Mr. J. Fenn and Mr. Viles. These were all admirably bloomed. There was a spirited competition in designs for gardens, and Mr. J. Hall carried off the silver cup for a very tasteful work, comprising a geometric garden and fountain very neatly finished; second, Mr. Spillman; third, Mr. T. Walker; fourth, Mr. Ball. A splendid lot of fine foliaged plants were kindly supplied by Mr. Prestoe, of Victoria Park, which added greatly to the attractions of the exhibition.

A generous and laudable step was taken by the committee to render the exhibition a means of enjoyment to a class of persons not overmuch blessed with recreations. All the aged men and women of Bethnal Green work-house were admitted free of charge, and each was presented with a bunch of flowers and a penny. The men were admitted on Monday, the women on Tuesday; the total number being 298.

MESSRS. LANE AND SON'S NURSERIES, BERKHAMSTEAD.

When we speak of Messrs. Lane and Son's "nurseries," we use the plural number with some degree of propriety, for the operations at Berkhamstead extend over several large tracts of land, and things elsewhere grown by hundreds are here to be found in thousands, and the whole scheme of operations is of princely dimensions. Should the term "princely" appear improper, we may call to mind that "merchant princes" are recognized as such, and there can be no reason therefore why we should not speak of nurserymen princes, and, as a corollary, of "princely" nurseries. The ride of twenty miles to Berkhamstead by the North-Western Railway is about as pretty a trip as one can make for a small change out of dusty London, and the scenery of Hertfordshire is always pretty; there are few great levels, the chalk constitutes the basis of a considerable portion of the country, and wherever we find chalk we have healthful breezes, and if there is any depth of loam upon it, the country is sure to be rich and green. Indeed, we expected something of a treat in another way, but was disappointed, for we remembered at starting that the poet Cowper was born in the parsonage-house at Berkhamstead, and that it is the subject of an allusion in his exquisite lines, "On the receipt of my mother's picture":—

'Tis now become a history little known,
That once we call'd the pastoral house our own.
Short-lived possession! but the record fair,
That memory keeps of all thy kindness there,
Still outlives many a storm, that has effaced
A thousand other themes less deeply traced.
Thy nightly visits to my chamber made,
That thou might'st know me safe and warmly laid;
Thy morning hounties ere I left my home,
The hyscut, or confectionary plum;
The fragrant waters on my cheeks bestowed
By thine own hand, till fresh they shone and glowed:
All this, and more endearing still than all,
Thy constant flow of love, that knew no fall,
Ne'er roughened by those cataracts and breaks
That humour interposed too often makes;
Adds joy to duty, makes me glad to pay
Such honours to thee as my numbers may;
Perhaps a frail memorial, but sincere,
Not scorned in heaven, though little noticed here.

I thought to see the house, perhaps to enter it, perhaps to touch the walls of the chamber in which the weakly child, born alike to misery and to fame, had experienced the tenderness of parental care that never passed from his memory, and which it was his consolation in after life to make the theme of one of the most tender, truthful, and touching of domestic poems in the English language. But, no, "time rolls his ceaseless course," and the noblest landmarks and the most sacred shrines are swept away in a torrent that commingles old and new, good and bad, and hurries all, except truth and virtue and the memory of good deeds, into the ocean of forgetfulness. The pastoral house has been rebuilt, not a scrap of the original edifice remains; nothing that can truly speak of Cowper remains on the spot, except the old well which is romantically clad with ivy, and appears a fitting memorial of the poet in its loneliness and simplicity, and a reminder that from the well of truth he dipped for treasures and drew them forth plentifully for the blessing of mankind. Talking of this matter with Mr. Lane, he told me with a touch of humour that the vicar who rebuilt the house wished to move the well, in order to have it nearer to the domestic offices, but found the task impracticable. But Berkhamstead is just the sort of place for the introduction of a poet to the world. Few such have been born in great cities. The beautiful hills and woods around are visible from almost every window in the place. The town itself is clean, prosperous, quiet, and in no respect deficient of public spirit. There is good cheer of every kind and mighty strong ale at the King's Arms, and for those who love *al fresco* delicacies, the fried sausages sold in the market on Saturday night, and to regale on which the farming men come into the town in companies, may be worth consideration. The only reason I abstained from tasting them, when I had a look round with Mr. Lane, was that they were too much like old curl-papers, and I have seen old curl-papers that with a little simmering in hair-oil would possibly turn out as nice-looking. As for other matters, the church is a most respectable structure with a heavy Norman tower, and in the town there are some old houses of very quaint character, dating from somewhere about the time of the Conquest, and which, except for their picturesqueness, would as well be obliterated by the conquest of modern improvements. And talking of improvements, there is a tremendously tall house here, a house that may be seen from all the hills around, and is more conspicuous, though far less agreeable to look at, than the church itself. It is a flat-faced, fanciful, red brick affair, a rectangular Tower of Babel, built by a thriving pork butcher who aspires to be nearer heaven than anybody else in the place, and so has capped his edifice with a miniature parade enclosed in fanciful railings, from whence he may behold the stars and antedate the time when he shall wing his flight through the midst of them. So much for Berkhamstead for the present; if I should live to write its history, I shall begin by saying, "This is a pleasant little town in Hertfordshire, wherein the stranger may find much to amuse him during a short stay, and be alike pleased with the civility and intelligence of the inhabitants and the capabilities of the best hotel to make him thoroughly comfortable."

Messrs. Lane and Son's home nursery may be reached in about five minutes by a slow pedestrian from the railway station. It is not of great extent, yet equal in that respect to any of the largest of the nurseries nearest to London, and it is interesting to a visitor of the horticultural stamp because here are all the glass houses and all the choice plants. After traversing a few quarters of variegated yews, *Wellingtonias*, *Thuas*, and

other useful trees, I made my way to the range of vineries, and learnt something of the secret of the great fame Messrs. Lane have acquired and long enjoyed as amongst the most successful grapo-growers in the world. These vineries extend across one end of the home nursery on a very gentle slope; they are all spacious span-roofed houses, in great part filled with young pot vines ready for planting out and immediate fruiting. There must be thousands of fine canes of all the best sorts known; not a spot to be seen on a leaf anywhere, the houses all kept as cool as possible with abundant ventilation, and great care taken to allow abundance of light for the finishing of wood. I shall not weary the reader with detailed descriptions of all the houses or all the plants I saw; but just come with me into the principal fruiting vinery, which is one of the many houses that constitute this range. The house is 126 feet in length, 24 feet wide, and 13 feet from the sill to the ridge. The vines are all planted in an outside border on one side only, and are trained up to the ridge and then down again to the other side. There are twenty-four vines in all, and the bunches hanging (many had been already cut) on the day of which I made note thereof numbered 996. The Black Hamburgh is the leading variety, but there are a few others, such as Black Prince, Lady Downes, Bowwood Muscat (which ripens with Hamburgs here), Muscat Hamburgh, and Trebbiano. The vines are all trained on the single-rod and close-spurring system, save one, and that is a Black Hamburgh, which carries a rod of its own and a rod each of Bowwood Muscat and Muscat Hamburgh. In this particular case of "extension," the one set of roots supports twenty-one bunches of Bowwood and eleven of Muscat Hamburgh, besides twenty of its own Black Hamburghs, a total weight of about 100 lbs. of grapes on three rods, and these trained as close as will allow without overlapping of the leaves. All through the house the grapes are fine, and there are many huge exhibition bunches of five or six or more pounds each; the Muscats are full ripe and splendidly finished; the bunches of Black Prince are remarkable for their colour and bloom, and the perspective is as charming as can be imagined of such an arcade of great green leaves and hanging grapes. It is worthy of remark that though Muscats ripen here perfectly, the amount of firing used is only just sufficient to give a little extra help to the vines in May; thereforeward King Sol is the stoker, and the necessary heat is obtained free of cost. Nor is the border unworthy of notice. It is rather narrow, and only so much raised above the level as results from the occasional mulching of the surface, but of course the roots go beyond it into the adjoining nursery quarters. Moreover, close beside the doorway of one of the houses in this range is a tank for dipping, and that shows the state of the substratum, proving that at five feet from the surface there is water.

It is from this house, as a rule, that Messrs. Lane cut all their exhibition bunches, and it is from this house, too, those huge pot vines are brought for the embellishment of exhibitions with the best pot vines ever shown. I saw the group of pot vines being prepared for the last Crystal Palace exhibition; there was a Buckland Sweetwater with wood as thick as any man's thumb, with abundance of fresh leaves and with twenty-one large bunches of ripe fruit; the other vines in this group were a Foster's Seedling covered with beautiful bunches, a magnificent Alicante with berries and bunches large enough to cut for show, and a pair of Black Hamburghs with twenty-one and twenty-three bunches each. When these had been cleaned up and were stowed in the van for transit to Sydenham, there remained many more such in the house, and a very large stock indeed of vines grown and trained in the same barrel style, all in fit condition for fruiting next year. I was told that of the many thousands of pot vines of all kinds and sizes I saw, very few would be left at the end of the season, and that a great many half specimen pot vines were sold, such as required only one season's good management in the hands of the purchaser to render them fit for exhibition. The pot vines are all plunged in sawdust, and there is just a plank laid down for a causeway through them. I had a lot of the pots turned over out of the holes, and looked at the bottoms of the pots of the vines that were packed for the Crystal Palace. Not one had been allowed to root through; the crock lay clean and close over the centre hole, they were as *bona fide* at the foundation as they were splendid in the superstructure; nothing in all England to surpass them. By the way, it would be good fun to see Mr. Meredith and Messrs. Lane show pot vines in the same class somewhere; let us hope for it.

From the vineries I went over to the pits, on the opposite side of the road, to see the pot roses. Here I found several thousands of roses of all sizes and all sorts, from little bits just filling small pots with roots to half specimens ready for forcing, or for any purpose to which pot roses from two to five feet high and of breadth in proportion can be adapted. All their own exhibition roses were grouped together out of doors, and had nearly shaken off their leaves, so as to present a rather unattractive spectacle of bare sticks; but it was agreeable to notice that they had made a good growth this season in spite of much travel and many hardships. Good news for lovers of roses and a great blow to those jackasses in the trade who tell my readers that "own roots" are impossible. Save and except when making standards, for which of course briars are used, Messrs. Lane have given up all the various stocks that have been competing for favour lately, and they have now ready for sale some *ten thousand roses on their own roots*, all in the most healthy condition, and they can be selected for any purpose, some being large and well hardened bushes fit for planting out this autumn, others neat little pot plants well adapted for shifting on to flower as miniature bushes in the greenhouse early in the spring. I have just heard that Messrs. Paul and Son, of Cheshunt, have ten thousand own-root roses to offer this season. So my doctrine will prevail at last, and those miserable pretenders who think because they are in the trade that they are "practical" men, and upon the strength of that "shibboleth" have taken pains to traduce me for my long and constant advocacy of own roots,—those miserable pretenders will go to the wall, and meet the fate they deserve for attempting to stop the march of science by putting their little shops in the way. If the opposition to my doctrine had continued much longer, I would myself have raised a million own-root roses, and have offered them to a few of the principal houses, in refutation of the detractors whose ignorance has made them vicious. But I am relieved of that task by the spirit of the two largest rose-growers in the country, and now all England may put the matter to the test of experiment.

The day following my exploration of the home nursery, Mr. Lane drove me to the nursery on the common, where Mr. Henry Lane is the resident manager. This is the most beautiful of the three nurseries belonging to the firm, as it is devoted to the growth of the choicest conifers, and all the great specimen trees are here. Rarely have I seen such a display of Araucarias; they were quite a reminder of Bicton. Besides these, there are immense stocks of *Picea nobilis* and *P. Nordmanniana*, Wellingtonias, yews, and many other subjects. Moreover, there are good stocks of every coniferous tree that is of the slightest use in gardens. I was particularly interested here in the rhododendrons and the kalmias, which are grown in the staple without peat, and cannot be beaten in respect of health and vigour by peat-grown plants anywhere. The loam of the common is of a soft silky texture, very deep, very

strong, decidedly dry, as it lies over a bed of gravel. The Araucarias and other robust-habited conifers make very stout wood and large deep green leaves in this soil, which proves it to be fertile, and whatever is taken out of it has an abundance of fibrous roots. I do not think it equal to the mellow hazely loam we obtain from Wanstead, but neither is it desirable for nursery purposes that the soil should be so rich as is commonly found in gardens. Trees transferred to a good soil from a comparatively poor one make a more satisfactory progress than trees taken from a rich to a poor soil; and therefore the most fertile spot should never be selected for a nursery, though it is to the interest of the nurseryman to obtain as rapid a growth as possible of whatever he commits to the ground. Wherever a pulverulent stony or sandy loam is met with—a loam that may be crushed between the fingers when damp without soiling them, or, at the most, leaving only a slight tawny stain—American shrubs may undoubtedly be grown without the aid of peat; but on the sticky black soils, or the adhesive brown loams and clays found in many of the best gardens, these plants will not last long. The only safe way to deal with them is to excavate and remove the soil to a depth of two feet at least, and in its place lay down good peat or silky loam, or a mixture of top-slicings of turf from a common with sharp siliceous grit, such as the drift from a gravel road.

My next day's rustication comprised a visit to Wiggington. Here is another great nursery, the management of which is chiefly in the hands of Mr. Frederick Lane. Here the soil is decidedly poor and of a gravelly texture, but the trees are remarkably healthy, and many kinds of conifers do well here, particularly Jnnipers, of which there is a vast collection of all the best kinds known. This ground also suits hollies well, and there are thousands of all sorts and sizes. In the hedge-rows round about Wiggington are very many hollies of great size, many of them twenty feet high and as much through; they are huge bushes of a lustrous deep green colour, and the leaves are prickly and smooth in patches all over them, so that twigs bearing smooth leaves only and twigs bearing prickly leaves only can be cut from almost any part of them. But in some places prickly and smooth leaves grow on the same twigs, and the grades of transition from one form to the other can be traced minutely. There are 57,000 fruit-trees here fit for sale, and they are trained and pruned in every conceivable manner. As to conscientious modes of doing things, I learnt here that it may be carried a trifle too far. On going through a great quarter of pyramid pears, I found the walks obstructed by great heaps of dead trees, and was told that these were thrown out because they could not be formed into symmetrical pyramids; many a poor man would be glad of such trees at a few shillings each, and I saw as many lying about as would fetch twenty pounds if sold extra cheap, because they had refused to make a few shoots exactly where required for perfect pyramids. However, I did not go there to play the censor, but to pick up a few matters of interest and usefulness for our readers, so I will direct attention to a few more agreeable subjects.

The Lanes are stubborn advocates of free stocks for all kinds of fruit-trees. They abhor the paradise stock for apples, the quince stock for pears, and the mahaleb stock for cherries. They say that starving stocks promote early fruitfulness at the expense of health and longevity; and being desirous that trees purchased of them shall be ever a credit to them, they proceed to lay a good foundation in every tree they grow for sale, and are content to lose the applause which may be secured by selling dwarfed trees precociously fruitful. Another point in the practice here that deserves remark is that whatever can be grown on own roots is so grown; in other words, grafting is resorted to only when it is found to be the best mode. Thus the new Japanese shrubs, which elsewhere are in almost every case grafted, are here grown largely on their own roots; a most decided advantage to the ultimate possessors of them. I shall now make note of a few special subjects that are likely to interest our readers.

CONIFERS IN CRATES.—A number of the best specimen Wellingtonias and other large trees are grown in crates, to facilitate lifting them with good balls of earth, so that when transplanted they shall produce an effect at once, without the risk of their being brown and bare for two or three seasons. These crates are made of rough rods braced round with galvanized wire; the trees root within and beyond them, so that there is none of the cramping that results from pot culture, and when they are taken up the whole ball and roots within the crate are preserved intact, and in the subsequent planting all that is necessary is to lower the tree into its place, and then, after loosening the wires, the wooden bars of the cage or crate can be removed, and the earth filled in to the ball.

CRYPTOMERIA ELEGANS is one of the most elegant trees in the nursery, but at present scarce and costly. The growth is naturally pyramidal, and in the style of a dense glaucous juniper. The tree is covered all over with blotches of dull red where the points of the young growth are; by this sign, irrespective of others, it becomes a very distinctive feature in a plantation.

CRYPTOMERIA LOBBII.—This is a pretty plume-like tree of a fine glaucous hue, worth a place anywhere in a garden. *C. Japonica* is scarcely grown here; it is almost universally a failure.

KOELREUTERIA PANICULATA.—A beautiful example of this handsome garden tree growing on a wall at the home nursery. It was richly adorned with racemes of yellow flowers two or more feet in length. Pity it is not better known, for it is one of the most elegant trees both in leafage and flowers, ever introduced to our gardens. For good figures of it see *Gardener's Magazine*, 1865, pp. 348, 349.

CASTANEA CHRYSOPHYLLA.—This is a charming miniature species of chestnut, with glossy myrtle-like leaves and small fruit that resemble the galls of the cymips found at this time of year on the wild-rose trees. It is of close twiggy habit; a very desirable tree for choice collections.

CUPRESSUS LAWSONIANA COMPACTA.—A very compact freely branching variety, of which many thousands are grown; it is no doubt the best form of this fine tree for general planting, and especially for lawns and shrubberies.

LIGUSTRUM CORIACEUM.—This will be one of the grandest of all the privet tribe, and a fine companion to the dark twisted-leaved holly. Large quantities are being raised on their own roots; hitherto, with this exception, I have always seen it grafted on the common privet.

CEPHALOTAXUS DRUPACEA.—This is here called *Taxus coriacea*; it is a very peculiar habit of very rigid upright growth, and dark solemn tint of green. The leaves are stiff, leathery, and slightly curled, and average an inch and a half in length. One of the finest trees possible for the terrace or geometric garden.

DUPLEX YEW.—They play some strange freaks here in grafting various kinds of yews upon each other. There is a large quarter of duplex yews of the most comical kind at the nursery on the common. They are Irish yews of about 6 feet in height; on the top of each a tuft of the golden Irish or the bright-coloured elegantissima is grafted; the result is a tall dark column surmounted with a golden brush. They dimly remind one of the monument

on Fish-Street Hill, the summit of which is crowned with a great golden flame, to commemorate the outbreak upon that spot of the Fire of London. These might indeed, for the sake of distinction, be called "monument yews;" and as they are so distinctive and curious, they would be well adapted to plant for commemorative purposes, for in private gardens the Wellingtonia is scarcely the proper tree for the purpose, because of the likelihood of its soon attaining to dimensions which might render its removal or destruction desirable. I have seen several mistakes of this sort,—the selection of a tree for a particular spot for which it must inevitably become in time as disproportionate as a giant in a doll's house. Another kind of union or duplex yew is made by grafting adpressa upon five or six feet standards of Irish yews and keeping the stems clothed with short twigs, like a green felt, while the head spreads out in the form of a huge table.

STANDARD PORTUGAL LAURELS.—A number of these on stems six feet high have been in training five-and-twenty years, and for a grand terrace garden are now in perfection.

RETINOSPORAS are plentiful of course, and they have all the species and varieties that have been introduced. They are all hardy at Berkhamstead. One of the most beautiful of them all is *R. pisifera aurea*, which is richly coloured and extremely elegant in proportions.

A BEDDING ROSE.—In passing through the rose quarters I was struck with the brilliant appearance of a mass of a well-known China rose, *Belle de Florence*, which was smothered with flowers of the liveliest cherry-pink colour. This is the best companion in the bedding way I have seen for Cramoisis supérieure, and equal to it in its profusion of flowers. Fifty of each in a pair of beds would be very acceptable for bold masses of colour.

PICEA NOBILIS GLAUCA.—This variety of one of the grandest of all known coniferous trees is intensely glaucous and lustrous, appearing as if silvered and burnished. It grows as freely as the type, and has a most striking appearance amongst the darker tones of colour of other hardy trees, and especially so if grouped with other conifers. A finer tree for a spacious lawn cannot be; every lover of the tribe should secure it.

CALLUNA VULGARIS FLORE PLENO.—A great bed of the double-flowering ling has a most delightful appearance at this season. It is a most beautiful shrub, producing long spikes of very double rosy pink flowers, exceedingly rich as compared with its single-flowering parent of the wastes. This ling and all the hardy ericas grow freely in the yellow loam of the common, and have a charming appearance, even when not in flower. This is the last note I can afford space for, and I close my book regretfully; for, next to seeing places, one of the most agreeable pastimes is to write about them.

S. H.

THE VON THORIGKEIT PALM.

A STORY OF ADVENTURES AND DISCOVERIES.

The town of Weisstadt, in Germany, is full of philosophers, mathematicians, and *savants* of all kinds. On entering the place the traveller is at once struck by the physiognomies of the inhabitants: all the faces are more or less like geometrical figures.

Herr Dummkopf, one of the innumerable professors who adorn Weisstadt, was rich though learned; and, nevertheless, something was wanting to complete his happiness. Every morning when he rose he addressed to himself the following remark: "Why did the traveller Bruce never discover the peninsula of Meroc, which Herodotus saw as plainly as he saw the moon?" This thought at last absorbed him so completely, that he could not refrain from packing up his shirt and starting at once for Egypt. He passed through France, crossed the Mediterranean without observing anything, so thoroughly occupied was he with the non-discovery of the supposed peninsula. After remaining a few hours at Cairo, he pursued his journey to the ruins of Carnæ. He bestowed a careless glance on the Colossus of Memnon, the crypta of Osimandias, the obelisk of Luxor, and all the wonders of Egyptian Thebes; and as he continued to ascend the Nile he saw Latopolis, Elethyd, Apollinopolis, and Syene. The ruins of these ancient towns were not honoured by a single mark of admiration; it was humiliating for the Egypt of Sesostris!

One day the sun was so hot at noon—a very natural thing in the torrid zone—that the learned Dummkopf allowed himself to be seduced by the cool aspect of the Nile, and determined to make an era in his scientific life by taking a bath in the sacred stream.

He looked around him. The desert was indeed worthy of its name. There was not even a statue of Isis, of Ibis, of Anubis, or of Serapis to be seen. The Nile flowed on in religious silence, and Dummkopf, reassured by the solitude which reigned around, hastened to take off his boots and clothes, and after arranging them carefully on the bank, plunged into the eternal river.

Dummkopf was grateful to mother Nature for having placed a cool refreshing stream by the side of the burning desert. As a boy he had been in the habit of swimming in the Rhine of his fatherland, and now, remembering the accomplishments of his youth, he struck out, turned over, floated on his back, dived, paddled like a dog, plunged like a porpoise, and again thanked mother Nature for having in her bountiful wisdom placed a cool refreshing stream by the side of a burning desert. He was continuing to disport himself like a fresh-water Triton, when suddenly, close to him, and in the middle of the Nile, he saw a huge green snout, adorned with lion's teeth, and lighted up with a pair of blood-red eyes.

Dummkopf instantly remembered that the Nile was fertile in crocodiles, and began to chide his memory for not having thought of that fact before.

In the meanwhile the monster was bearing down on the imprudent bather, who, though thin, by reason of excessive study, was at the same time a very acceptable meal for a hungry crocodile.

For it was indeed a crocodile, and of the finest kind—a colossal and amphibious lizard, more ferocious than the tiger of Bengal or the lion of the Atlas.

Dummkopf made straight for a little island—the terror of navigators and the salvation of swimmers. He had almost reached his place of refuge, with the crocodile so close on his heels that he could feel its warm breath on the soles of his feet, when he remembered that the monster was amphibious. Another man would have been paralyzed by this reflection. Not so Dummkopf. He looked before him, and seeing a friendly palm-tree within reach—it was the solitary ornament of the little islet—he ran to it, took a spring, and climbed up its branches with the agility of a squirrel.

Having perched himself in safety near the summit, the learned professor looked down upon the Nile. The crocodile was issuing slowly from the water, shaking, as he did so, his coat of glittering scale-armour. He

then walked along the sand like a fish that had suddenly become a quadruped, and gradually approached the foot of the palm-tree.

Dummkopf ransacked his memory for all he had ever read about crocodiles, with the view of ascertaining whether Pliny or any other natural historian of celebrity had ever stated that they were able to climb up palm-trees.

It appeared to him that both Pliny and Saavers had testified to the climbing capabilities of the crocodile.

"Oh, Philosophy," he mentally exclaimed, "grant that my brethren, who make mistakes in every page, may also have erred on this point!"

Suddenly he remembered with a shudder that he himself had written an article in the *Weisstadt Review*, in which he maintained that crocodiles were in the habit of climbing up trees like cats. He wished now that he had thrown the article into the fire; but it was too late. All Weisstadt had read it. It had even been translated into Arabian, and no author had yet contradicted it, although it had penetrated to Crocodilopolis itself.

The amphibious monster approached the palm-tree, looked up, and evinced the most lively joy at discovering Dummkopf among the branches. It walked round and round, looked up again, and then, recognizing the impossibility of taking the stronghold by assault, sat down, as if determined to reduce it by blockade.

Here we must render homage to true science. Dummkopf, in spite of the pre-occupation of the moment, was filled with regret when he found that, contrary to what he had stated in the *Weisstadt Review*, crocodiles did not climb trees. He saw that he had committed a gross error in Natural History, but he at the same time made up his mind never to correct it, if, by a miracle, he escaped from his present perilous position. He had made the statement with a full conviction of its truth, and it added one more fact to Natural History. Crocodiles climbed up palm-trees. It was impossible to deny it now, even after sitting on a palm-tree up which a crocodile had been unable to climb. The conclusions of science must not rashly be interfered with.

In the meanwhile, the crocodile lay stretched out at the foot of the palm-tree, in calm anticipation of Dummkopf's inevitable descent. From time to time the animal testified, by the wagging of its tail, to the pleasure it experienced in looking forward to that incident.

The naturalist, to do him justice, did not lose the opportunity of studying the habits and manners of the Egyptian crocodile; but having viewed the animal in a scientific spirit, he again trembled for his life, for it was now evident that the blockade was to be kept up in earnest.

Hours of suspense and of imprisonment consist of 240 minutes each, but they come to an end at last. Time sometimes goes on cruiches, but it proceeds nevertheless. The sun went down as on the previous evening, and after a very short period of dusk the last rays of departing daylight exhibited the crocodile lying at the foot of the palm-tree, placid and horizontal.

The Professor now searched in the store-house of his memory for some instance of a man who had passed the night on the top of a palm-tree. After going through the whole of ancient and modern history, he commenced the department of travels, and suddenly bethought him of "Robinson Crusoe," which, though not usually accepted as a book of travels, is far more truthful than the great majority of works of that class. Now, Robinson Crusoe passed the first night after his shipwreck in a tree, and this tree was in all probability a palm-tree. "Why, then," said Herr Dummkopf, "should I not do the same?"

And, still fortifying himself with the example of Robinson Crusoe, the Professor drew some of the smaller branches around him, and composed himself to sleep.

But the night was long, and Dummkopf slept but little. He dreamed that he was at Weisstadt, delivering a lecture which proved that the crocodile was a fabulous animal like the sphinx, when suddenly a shower of crocodile's tears fell on his face. He awoke with a start, and was very near falling down on to the tail of his besieger.

The crocodile was now, in all probability, fast asleep, and Dummkopf resolved to play him a trick. "If," said the Professor, "I could slip down the tree, and swim across the Nile without its hearing me, it would be nicely caught when it awoke in the morning and found me gone." But having reflected that he might be caught himself, he abandoned this desperate project, and merely resolved not to go to sleep again that night.

When day broke, the Professor saw that the crocodile had not been idle during the night. Instead of sleeping, he had been fishing on the banks of the Nile, and the bones with which the ground was strewed showed that he had not fished in vain. The monster had now had his first course, and he looked upwards towards his intended victim as if to say that he was quite ready for the second.

The Professor had certainly a terrible future before him. The contest between the besieger and the besieged was by no means equal, for the former could find as much food as he required in the waters of the adjacent Nile, while the latter saw no prospect of obtaining the slightest nourishment, and would in all probability either die from starvation or fall fainting into the jaws of his voracious assailant.

In the meanwhile Dummkopf's stomach, a machine which in some respects is quite independent of the brain, began to murmur loudly, for it had been deprived of two meals—the supper of the previous evening and the morning's breakfast.

Among a great many other things of which the learned Professor was ignorant, he did not know that palm-trees produced dates, a rich pulpy fruit, on which the Arabs have contrived to live very well since the time of Adam, the first colonist of Arabia. However, a short time after sunrise a ray chanced to fall upon a large bunch of these valuable articles of food, which the Professor at once recognized from having seen them in the grocers' shops of his fatherland. In Germany he had been in the habit of breakfasting on beef and sausages, supported by several slices of bread, and washed down by several glasses of wine. But in the desert he was obliged to content himself with whatever manna he could get, and to be thankful, moreover, that Providence had sent him any. He ate dates by the handful, and felt much strengthened by his repast.

After breakfast a strange and superstitious idea occurred to the Professor. He had read somewhere that crocodiles were the natural avengers of all the insults offered to Egypt by barbarian travellers. It appeared to him that there was some sense in this, for if crocodiles didn't serve to avenge something or other, he was convinced they could serve no purpose at all. Then he reflected that he had passed without notice the statue of Memnon, the colossal torso who had just commenced his morning's cavatina under the influence of the sun's rays. The divine Osimandias and the Pharaohs, as represented by the sublime pyramids, had been

treated with similar disrespect; and the Professor now repented his irreverence, and vowed to kiss the big toe of Memnon, the highest tenor in the world, if he only escaped his present danger.

After this vow the illustrious Dummkopf became more tranquil. He looked down at the crocodile, but the vow had produced no effect upon him. He did not even seem to have heard it. There he was still, watching patiently for his prey.

Dummkopf was now dying for a mouthful of cold water. Dates possess the property of producing thirst. Hence they are very desirable at dessert, if the host wishes his guests to pass the bottle freely, but not otherwise. For a professor at the top of a palm-tree from which he is unable to descend, they form the most unsuitable food that can be conceived; but Herr Dummkopf had no choice—he had either to eat dates or die of inanition. He was like Tantalus: the river was flowing at his feet, but he was unable to get a drop of water wherewith to moisten his parched lips. He again compared his position with that of Robinson Crusoe, and found that all the advantage was on the side of the latter. It was true Robinson Crusoe passed a night on a tree, but he came down the next morning, killed parrots, made them into fricasseed fowl, drank rum-and-water, walked about with an umbrella over his head, met no crocodiles, and found a man Friday. "Happy Robinson Crusoe!" exclaimed Dummkopf; "and yet he complained. I should like to know what he'd have done in my place, on the top of a palm-tree."

Suddenly the sky became overcast, and the Professor was filled with a joyful anticipation of rain. He had already joined his hands so as to form as large a receptacle as possible for the drops, and was promising himself a regular aquatic orgie, when all at once he remembered that in Egypt it never rains.

The crocodile seemed to understand the sufferings of the Weisstadt Tantalus. He walked to the edge of the river and swallowed several quarts of water, at the same time casting ironical glances at the unfortunate Professor. The pleasantries of masters is always intolerable. Dummkopf was disgusted and enraged; but this only increased his thirst.

He cast his eyes along the Nile, in hopes of discovering some providential sail. But then he remembered that in that part of the river, above the rapids, there was scarcely a chance of meeting with a boat of any kind. A death-like solitude reigned around, and nothing was to be seen but dark ruins, among which an occasional ibis, motionless, like a mark of admiration, was perched.

Again the Professor turned his thoughts towards Robinson Crusoe. "Certainly," he said to himself, "if Crusoe had been in my position, at the top of a palm-tree, he would somehow or other have found means to obtain a drop of water. Come now, how would he have done it?"

Dummkopf's mouth was on fire, and there was the great Nile rolling calmly and majestically before him.

At last Necessity, who is known to be the mother of Invention, brought her ingenious child to his aid.

The Professor clapped his hands. He had discovered a hydraulic process which would enable him to appease his thirst. How little is required to give joy to poor human kind! Here is a man on a palm-tree—a dying man who cannot escape from the jaws of a crocodile—and because he has discovered a very equivocal means of obtaining a few drops of brackish water with which to moisten his parched lips, he is convulsed with delight.

Dummkopf was proud of competing with Defoe's hero, and set to work without delay. He began by breaking off from his palm-tree several long branches, which he spliced together by means of fibres. He then waited until the crocodile entered the water for a few minutes—by way of keeping up its character as an amphibious animal—and extended his apparatus towards the river. The leaves at the extremity of the machine imbibed a considerable quantity of water, and the Professor, drawing back his improvised pump, refreshed his calcined lips by means of the saturated foliage. He repeated the experiment several times, and, in fact, gave himself up to all the excesses of intemperance. This was an ingenious device, for which Tantalus would have given his eyes.

But, above all, Dummkopf was amused at the notion of mystifying his crocodile, who, as for that, richly deserved it.

Having no longer any anxiety as to the means of satisfying the two chief wants of existence—hunger and thirst—the Professor now began to think how he should manage for his clothes. His aboriginal costume was admirably suited to a tropical climate during the day, but remembering that during the night he had felt rather chilly, he resolved to make himself without delay a garment of green leaves. Besides, how was he to appear before the public without clothes, if by chance a boat should present itself?

Dummkopf accordingly gathered in his aerial aloof a certain quantity of the largest leaves he could find, and, crossing his legs like a tailor, proceeded to make them into a vegetable paletot, which could not be said to belong to the latest fashion, but which, on the other hand, had a primitive cut about it that was highly picturesque. Two leaves sufficed for the nightcap, which, original or not as its appearance may have been, at all events looked much better than the hats we wear in open day.

Here was Dummkopf now lodged, fed, and clothed at the expense of nature. Happiness is altogether relative; and, for a time, Dummkopf was happy indeed. He was proud of his inventions, and from the height of his palm-tree looked down upon Robinson Crusoe with contempt.

As he was reflecting calmly on his happiness he saw the monster, no longer horizontal, at the foot of the tree. He was making one last endeavour to take it by storm, but, failing in the attempt, had forthwith recourse to sapping and mining. He went to work with the air of a crocodile who had made up his mind, and who had said to himself, "There must be an end to this."

Dummkopf, shuddered as he heard the teeth of the monster grinding against the bark of the tree.

But the molars and incisors of the crocodile are so arranged that they can do no serious harm to the palm-tree; they can tear the bark off, but cannot pierce or crush the trunk. Dummkopf, however, was ignorant of this fact, and expected every minute that his asylum would fall to the ground, and leave him a prey to the horrid monster, into whose scaly body he would enter as into a tomb of shell, but without the smallest epitaph to inform the world of the numerous virtues he possessed.

The crocodile next attacked the tree with his tail as with a battering-ram. How the Professor quivered when the tree shook! And the worst of it was, that, independently of the most terrible result that could possibly take place, there was the certainty that the Professor would lose a large portion, if not the whole, of his provisions, unless the monster desisted from

his sanguinary assault; for with each blow from the crocodile's tail down came a bunch of dates, and when, as often happened, the fruit fell on the animal's back, his fury redoubled.

At last Dummkopf could stand it no longer. Convinced that life was not worth defending at such a cost, he resolved to throw himself from the top of the palm-tree, in order to find repose in death. Full of this desperate idea, he stood up, put aside the branches which might have kept him back at the edge of the precipice, and thrusting one foot resolutely forward, kept the other firmly in its place. An honourable thought checked him on the very brink of the abyss. Dummkopf had no family, no wife, no children, no nephews; it was his duty, then, to remain in the world as the sole representative of the Dummkopfs. Man is ingenious, even in the midst of his despair. If he has a wife and children, he wants to live for their sake; if he is alone in the world, he will live for his own benefit.

Dummkopf was very grateful to himself after coming to this heroic resolution. He even called himself a coward for having entertained for an instant the idea of offering himself up as a sacrifice to the voracity of an amphibious monster.

As he now determined not to die if he could by any means avoid it, the Professor began to consider whether it would be possible to enjoy, at the top of this palm-tree, that sort of happiness which a civilized man has a right to expect. The crocodile had expended all his force in vain. It was evident that the palm-tree was an impregnable fortress, as far as his attacks were concerned. The climate was superb. At the foot of the house—that is to say, the palm-tree—ran a magnificent river. Thanks to the hydraulic apparatus, there could never be any want of water; and as for food, there were dates in abundance. The crocodile, instead of being terrible, was now only amusing; and as it was clearly proved that the palm-tree could suffer no injury from the monster's wrath, the Professor, in his lively moments, sometimes went so far as to pelt him with date-stones.

Every morning, when the sun rose, Dummkopf bent his ear towards the desert and listened to the cavatina of Memnon, the colossal tenor. Then, after breakfast, if he was pleased with the crocodile, he threw him down a few rotten dates, and was amused to see how voraciously the monster devoured them. Between breakfast and dinner he read in the library of his memory, and studied the mysterious monuments by which he was surrounded. When a profound thought occurred to him, he took a stylus, formed out of a twig, and jotted it down on a leaf, which served as papyrus. Then he read it over several times, and put it away in a place of safety.

There were no neighbours to watch his conduct, no journals to criticise his thoughts, no tax-gatherers to trouble him about overdue rates. He was as free as the air, and only wondered why the misanthropes of society did not imitate Simon Stylites or himself, and retire for the rest of their lives to the top of some column or palm-tree.

We must now leave our anchorite in his palm-tree, and proceed to the opposite bank of the Nile, where Herr Von Thorigkeit, the celebrated botanist of Berlin, was engaged in a hopeless search after yellow lotuses. Herodotus, it is true, saw yellow lotuses, but then Herodotus possessed the peculiarity of seeing things that did not exist. At all events, since his time the yellow lotus has not been met with, and for that reason conscientious botanists are perpetually looking for it.

Herr Von Thorigkeit, then, was searching for the yellow lotus, and he was accompanied by two Arabs armed with carbines.

There are some things, ordinary enough in themselves, which have an overpowering effect on the imagination, when they are seen in the desert. What, for instance, would be the feelings of a traveller who should discover in the midst of the Sahara a neat little house, with the words "Reading room, admission one penny," over the entrance? Von Thorigkeit was behaving naturally enough when he uttered a cry of dismay which resounded along the left bank of the Nile.

He had seen two boots, one proud and erect, the other bent down as if with fatigue. Dummkopf's clothes had disappeared, carried away by the stream, or perhaps swallowed by some omnivorous crocodile, but there were the boots standing on a ledge of rock.

The legitimate dismay of the botanist will now be understood. He had seen two boots on the left bank of the Nile, one proud and erect, the other bent down as if with fatigue.

The faithful Arabs, who had never seen a pair of boots in their lives, became terrified with the terror of the botanist, and bravely fired at the Wellingtons, which fell riddled with balls.

From the top of his palm-tree the Professor heard the report, and at first felt inclined to curse the troublesome individual who had come to disturb him in his solitude and meditation. But human weakness at last gained the day, and he resolved to make signals of distress to the three men whom he now perceived on the left bank of the Nile.

He broke off a long branch of the palm-tree, stripped it of its leaves everywhere but at the end, where he left a large tuft, and waved it vigorously above his head with one hand, while with the other he threw into the Nile a quantity of dates, the only projectiles at his command.

The botanist, who was surrounded by that silence which is known to aeronauts alone, turned round at the sound of the dates falling into the water, and this time experienced a surprise which was greater even than the former one. The apparition of the boots was forgotten: he saw a palm-tree with a lofty crest, which waved to and fro in the midst of a perfectly calm atmosphere! After the first shock, this discovery caused him infinite delight, and he would have given all the yellow lotuses in the world for this phenomenon of a palm-tree.

Von Thorigkeit opened his note-book and wrote in it the following lines:—"In Upper Egypt there exists a kind of palm-tree which possesses the peculiarities of the aloe, with this difference, however, that the stem of the aloe attains an elevation of twenty feet above the level of the soil, and remains motionless, while the palm-tree of Upper Egypt agitates the top of its stem vertically and with a movement of prodigious regularity. We have named this tree the Von Thorigkeit palm."

Having written this, the botanist made a sketch of the palm-tree and showed it to the two Arabs, having no other public to exhibit it to. The children of the desert, with their lynx-like eyes, had just discovered a human form beneath the thick foliage of the island palm-tree, and they resorted to the most energetic gestures in order to make the botanist see it too. But Von Thorigkeit could think of nothing but the grandeur of his discovery, and the beauty of his drawing. He paid no attention to the gestures of the Arabs, and thought only of the sensation that would be produced in the learned world by the Von Thorigkeit palm.

The two Arabs persisted in their pantomime, which said as plainly as possible, "Look there on that little island; there is a human being there

up in the palm-tree; he is in danger; he is making signals, and we must go to his aid at once."

Von Thorigkeit pulled out a pocket telescope, shrugging his shoulders at the same time with the air of a man who makes a concession merely from politeness, and looked carelessly towards the Von Thorigkeit palm-tree. He had now his third surprise within the hour—the last completely absorbing the two others. He had seen distinctly a human face, and even a German face, surrounded by leaves; and a human hand shaking a naked branch with a tuft of foliage at the end. He replaced his telescope in his pocket with regret, read his article again, cast another glance at his drawing, and after reflecting, like Brutus, whether he should destroy his two children or let them live, decided at length upon the latter course. "Well, so much the worse," he said to himself: "what is written is written, and I shall not cut out a single word. Besides, as the aloe exists, the Von Thorigkeit palm-tree might have existed, if nature had only seen its utility; I see its utility, and I shall let it remain."

This resolution having been taken, the three men held a council. The first thing to do was to find a boat, which, after two hours' walking, they met with. It was a fishing vessel, and the botanist had only to hold out a piece of gold and to point to the river, in order to make the fisherman understand what was required of him. He then pointed down the stream, and said, in a haughty voice, as if the fisherman was likely to understand him,

"The island of the Von Thorigkeit palm-tree!"

The pantomimic direction would have sufficed.

They descended the Nile. The island of the Von Thorigkeit palm-tree was soon visible; and, as they approached it, the Arabs, with their lynx-like eyes, manifested some uneasiness, and exchanged signs of intelligence. After a quarter of an hour's rowing, doubt was no longer possible. They had really seen an enormous crocodile keeping watch beneath the palm-tree.

They imparted their discovery to the botanist, who now received his fourth surprise in the course of the day, and trembled with cold in a temperature of 100 degrees Fahrenheit. However, for the honour of his fatherland, the learned German endeavoured to conceal his alarm, which, it must be admitted, was natural enough on the part of a hotanist, who was accustomed only to hunt for flowers, and who had nothing whatever to say to the amphibious monster of the Nile.

The Arabs were talking quietly among themselves, like men accustomed to hunt crocodiles. They put fresh caps on the nipples of their guns, stood up firmly in the forepart of the boat, and told the fisherman to be careful with his oars.

The crocodile saw the boat approaching, but did not know whether it brought prey or peril to his shore. In the meanwhile, he made ready either for defence or flight, according to the number and importance of the invaders. He lay stretched out at the edge of the river, as motionless as a crocodile in a museum; but he kept his mouth wide open, ready to swallow the first enemy who landed.

The two Arabs, who were thoroughly acquainted with the habits and manners of the animal, took aim, uttered a syllable at the same moment, and their two shots sounded as one. The bullets entered, at the only vulnerable spot, the open mouth, and went through the whole length of the crocodile's body.

The monster shook his head with contortions so comic, that they called forth shouts of laughter from the first floor of the palm-tree. Then, casting forth a torrent of blood upon the sand, he closed his tearful eyes, and moved no more.

Dummkopf arranged his vegetable costume the best way he could, looked for his gloves merely through habit, and not finding them, came down as he was. The Arabs, like all their race, were grave men, but their seriousness disappeared in the wildest laughter when they saw Dummkopf's costume. The botanist himself, now re-assured by the death of the crocodile, could scarcely restrain his hilarity; but he bit his lips, and after shaking hands with his fellow-countryman, begged him to communicate his adventures. Dummkopf commenced by requesting his learned friend to check the unbecoming mirth of the three Arabs, who were threatened with the vengeance of the Prussian consul in case they did not instantly desist.

Then Von Thorigkeit in the most gracious manner offered Dummkopf his paletot, which Dummkopf naturally accepted, retiring for some minutes behind the palm-tree, in order to change his clothes, as he expressed it, though he might have said to dress himself.

Having taken a solemn farewell of his palm-tree, Dummkopf got into the boat, taking with him the crocodile and the coat of leaves as reminiscences of his adventures, and also as corroborative proofs. These precious relics were destined for the "Neue Museum" at Berlin, and Herr Von Thorigkeit, who was attached to the Berlin University, hastened to thank Herr Dummkopf in the name of the Prussian capital.

Dummkopf was equally courteous to the worthy hotanist. He thanked him in the name of science for his discovery of the Von Thorigkeit palm-tree, which added another member to the already numerous family of palms. He even promised to write a notice in the *Weisstadt Review*, to prove that the palm-tree just discovered, through the indefatigable zeal of Von Thorigkeit, belonged to the same species as the aloe of Ceylon.

At the nearest village a complete Arab costume was procured for Dummkopf, who, with the honesty which always distinguishes true science, restored the paletot to Von Thorigkeit.

The two friends returned to Germany together, and soon afterwards an article signed Dummkopf appeared in the *Weisstadt Review*, in which full justice was done to the labours of the intrepid botanist and traveller, Von Thorigkeit, who had discovered the Von Thorigkeit palm-tree at the risk of his life, and not until he had killed two black reptiles of the cobra capella species. The article was illustrated with a woodcut, which represented the new tree agitating its tuft in the air.

Von Thorigkeit also did his duty, for as soon as he reached Berlin he made known to the world that Herr Dummkopf, who had ventured above the third cataract, had rectified the errors of all the previous maps, and that in the course of his expedition he had killed two crocodiles by means of electricity.

Those who have meditated on the nature of man will not be astonished to hear the end of this true story. Dummkopf is at present the proprietor of the *Weisstadt Review*. He is a lecturer in the Weisstadt University, and in addition to all this, he has a wife and six children. Well, in spite of the Review, in spite of the lectureship, in spite even of his wife and six children, Dummkopf, at certain moments, regrets the peaceful life he led in his aerial apartment at the top of the palm-tree.

Such is man!—a being full of contradictions!

ORNAMENTAL-LEAVED PLANTS FOR FLOWER-GARDEN.

The desire for novelty, or rather for a change of sameness in our bedding system, has caused some of our horticultural friends to recommend the introduction of various kinds of vegetables to be cultivated for the effect they would produce as foliage plants. I, for one, cannot accord with the recommendation, as I consider they are entirely out of place in the flower garden. My convictions on that point were greatly strengthened on witnessing a quantity of beet employed for the said purpose in the Royal Botanic Gardens, Regent's Park. I could not see that they were in any way a substitute, either in quality or effect, for the many good ornamental-foliage plants we have already in the list of our flower-garden decorative plants.

But, of all things, why should we not endeavour to give more attention to their arrangement in their proper sphere, the kitchen garden, where they could be made to fulfil two purposes—that of use for food and beauty to the eye? A well-kept kitchen garden can be made equally attractive with the pleasure or flower grounds, if effect and order are attended to. I remember, a season or two ago, visiting one of those gardens in which such attention was bestowed on the growth of vegetables; and the first thing, on entering, that I beheld was a plot of Pine-apple Short-top beet. The whole of the plants presented such uniformity of growth and similarity of colour, that they conveyed a pleasing impression to the beholder. Is it not, then, possible to make every class of vegetable, when growing in their proper quarters, so far conformable to our individual appreciation of all that is beautiful, and not seek to transfer them to positions for which they are altogether unfit?

With these remarks I will enumerate a few of the most desirable of our foliage plants for the flower garden, and which I believe cannot be surpassed for splendour of effect when judiciously used, as the present is the season to correct or otherwise improve our plans for the ensuing year, especially as the summer is not too far advanced to judge of their intrinsic merits.

Iresene Herbstii (syn. *Achyranthus Verschaffeltii*).—I have not observed in my rambles among flower beds this summer many examples of this beautiful plant. I cannot account for its omission, for it is a plant that with me grows freely; besides, it is very readily propagated, either in the spring or autumn, is not at all difficult to strike, and can be preserved with ordinary care in a cool house during the winter, and increased with far less trouble than *Amaranthus melancholicus*, and in vigorous growth excels it by many degrees. In respect to colour, its dark crimson, intermixed with shades of bright carmine, have a very charming effect during fine weather. Its compact habit is also a recommendation for its general culture.

Centaurea gymnocarpa.—For the centres of large beds, or as single specimens to be planted at certain distances, either as a relief to the panel or other system of hedging, nothing of its character can well exceed its elegant and graceful form, growing, as it does, from two to three feet in height. In the large conservatory of Holland Park House, Kensington, Mr. Dixon, the respected gardener there, had this spring a great number of them as single specimens growing in pots, and their beautiful silvery pinnated foliage stood out in bold relief to the many green leaf plants not as yet in flower, as *Azaleas*, &c., &c. It can either be increased by cuttings or from seeds.

Chrysanthemum Sensation.—The first time I saw this bedded out in any quantity was this year, at Battersea Park, and I was particularly struck with its beauty; its silver-like foliage, view it which way you will, is remarkably striking. It cannot fail to become a popular favourite as an ornamental plant.

Pyrethrum parthenifolium aureum (the "Golden Feather" Pyrethrum).—This valuable addition to the list of our coloured leaf plants for flower garden decoration was sent out for the first time this spring by Messrs. E. G. Henderson and Sons. When I saw it in their collection, I had some doubt as to whether it would preserve its colour throughout the season when bedded out, but that was quickly dispelled by witnessing its effect as an edging plant in Battersea Park, where its golden-coloured leaves presented a fine contrast to the many other plants that it surrounded. They say it is quite hardy; if so, it is the more acceptable. Its flowers are very insignificant, therefore they require to be picked off.

Poa trivialis argentea elegans (Variegated Meadow Grass).—This plant was issued to the public by the same firm as produced the *Pyrethrum*. It is a very neat-growing grass, not so luxuriant as *Dactylis glomerata*, nor is it so strikingly effective; its blades are more inclined for an erect growth than the latter. In my opinion, it will become a very useful plant for vases or suspended baskets. Perhaps it requires a much higher state of cultivation to give it luxuriant growth than I have seen.

Dactylis glomerata (Variegated Cocksfoot Grass).—For effect, both in the distance and close to it, nothing belonging to the list of dwarf grasses can surpass this beauty, or I may even say equal it. Its habit is very graceful. If you wish to keep it close and compact, do not plant it in too rich a soil, nor supply it with much moisture, unless withering from the effects of drought. I have a large quantity of it planted out as an edging plant to a ribbon border alternating with *Lobelia*, and the difference of growth is observable at a glance at the spots where the soil is rich and moist, and, on the contrary, where the soil is poor the growth is more moderate. This grass is perfectly hardy, and almost any amount of rough usage will not destroy it; but better plants may be produced if you take them up and divide them into small pieces, potting them into small 60-sized pots and keeping them in a cool frame during the winter months.

Cinocaria maritima.—This is a far more useful plant as a second row edging to large beds and ribbon borders than it is generally regarded. In a large public garden within a few minutes' walk of my residence there are large quantities of it employed for edging the larger-sized beds, in connexion with Purple King Verhena, the latter forming the outside row; and the display of colour afforded may be said to be perfect, being both soft and pleasing, especially towards the close of the day. If some of the plants are taken up now and potted, they will assist to ornament the conservatory during the remaining autumn months. It can be raised in any quantity from seed. Seed sown now, and allowed to remain in the seedpan during the winter, and then pricked off early in the year, or if sown early in the spring, they will make good plants by the time you require them for hedging.

Gnaphalium lanatum.—The great value of this white or silver-leaf edging plant is that it makes an excellent outside border for tall weak-growing plants, as, from its quick but bushy growth, it forms an excellent

support to such plants as *Plox Drummondii* and *Calceolaria amplexicaulis*. It can be kept in good trim during the summer season by pruning and pinching, and in the autumn allowed to grow a little free, with the object of keeping the bedding plants in their place. It strikes readily, but as soon as the cuttings are rooted the shoots should be topped.

Stachys lanata.—This gray woolly-leaved plant is perfectly hardy; of this I am quite satisfied from the severe test it was subject to last winter; for in Kensington Gardens there is a walk, I should say, upwards of a quarter of a mile in length, and there are two borders extending the whole distance parallel with each other, the inside edgings of which are composed entirely of the *Stachys*; and I could not observe, on the return of spring, that it suffered in the least from the nipping frosts of the past winter. As you paraded the walks it wore a very cheerful aspect during the dreary season of the year. To look neat and well, it requires to be kept thinned in the growing season, both of leaves and shoots. In fact, this rule applies to all fast-growing ornamental plants. It is readily propagated from offsets.

JOHN P. McELROY.

ON THE FORMS OF ROSES.

Loose and inaccurate definitions in any pursuit are highly discouraging, and often lead to its abandonment in disgust. In the charming and popular pastime of rose culture, which has almost reached the dignity of a science, this inconvenience is specially felt, in the unreliable descriptions of "form" and nomenclature of "colour," so that those who are compelled to form their ideas of novelties from mere phraseology totally fail to realize anything like the truth. To speak, for instance, of the subject of form: it is quite sufficient for it to be recog-

Reflexed.

Expanded.

Cupped.

Half-cupped.

Globular.

nized as a canon of beauty that a rose should be "cupped," and forthwith every variety produced has the desirable property assigned to it, whether round as an apple or flat as a pancake; nay, it is not too much to assert, that could a square flower even be brought out, such would receive the designation of cupped, so long as that configuration is considered an essential recommendation. The original offence, no doubt, rests with the French raisers, who in their anxiety to disseminate their wares, indulge in the national genius for hyperbole, and picture forth their productions in romantic terms, rivalling the flowery language of the East. It may be urged that it is a difficult task to describe accurately the shape of any flower, varying, as that does, with the period of growth; some roses, for instance, being globular when partly blown, and cupped or expanded when fully developed. But it should always be understood that "form" should be decided when the flower is at its best, just before its "blasé" development by sun and air; and that its true contour can be most distinctively ascertained from a profile view, the flower being held level with the eye, because then differences can be most distinctly perceived. When examined from this aspect, it will be found that the arrangement of the petals of roses materially differs. In some, the centre is the highest point of the flower, the petals turning back outwards, and gradually increasing in dimensions to the outer row. This form, as exhibited roughly in No. 1 of the diagram appended to this paper, might receive the technical appellation of "reflexed," representing an extensive array of some of the best varieties amongst our modern roses, of which the old favourite Jules Margottin, when in proper character, presents an admirable type, being as eyeless as the "Mouster Polypheme" after the crafty Ulysses had extinguished his solitary orbit. A modification of this particular style of contour is exemplified by another old and valuable rose, representative also of a numerous class, *Baronne Provost*. This section of flowers might appropriately be denominated the "expanded," in the diagram shown as No. 2.

Let us take, again, a style completely opposite to these, wherein the outer petals are the largest, placed somewhat uprightly, containing and supporting, as it were, the interior leaflets, more or less in number; for, be it remarked, it is in this line want of doubleness most frequently prevails. Here is exhibited the true "cup," No. 3, out of which, were the exterior of sufficient solidity, we might partake of that beverage "which cheers but not inebriates," garnished with an additional whiff in the tea-scented varieties, far superior to the rose puddings of Roman epicures, which must have been rather physicky eating, although perhaps good for coughs. This con-

figuration of flowers appears in a modified form as the "half-cupped," No. 4, or tazza-shaped, the profile being much shallower than the cupped, though the outer petals are still the largest. Lord Raglan, and many of the same style, form representatives of a formation gradually going out, though some of the kinds are very beautiful when in perfection.

The fifth of representative types should be termed the "globular," No. 5; solid and substantial every one of them; sometimes hard to open; usually upright growers, with robust wood. In some cases the points of the petals roll over, though the ball-like contour of the flower is usually preserved. These may be considered the primary shapes, which embrace almost all the roses in our gardens. It must not be forgotten, however, that in some cases the petals are imbricated—that is, crimped or puckered, the petals being arranged longitudinally with respect to the centre; that in others they are short and close, presenting the appearance of the summits having been shaved off; and in others, again, they are completely incurved, being closed at the top, like *Madame Pierson* and *Globosa*, and seldom opening at all. When they do expand, however, they belong to the category of cupped roses. The finest example of an imbricated flower may be found in *Madame Moreau*, which presents a striking resemblance in form and arrangement to a show hollyhock, and is certainly novel and interesting.

If every popular rose, whether new or old, were classed under its characteristic form upon some such system as indicated above, or were certain well-known and distinct roses selected as types of styles to which all resembling them should

be referred, with further particulars of growth, colour, and foliage, rosarians would be enabled to understand better what they were about; descriptions would convey definite ideas; speculating in new roses would become a pleasure, instead of being, as too often at present, a disappointment, or, to use a popular phrase just now, "a leap in the dark."

W. D. PRIOR.

NOTES OF A TOUR THROUGH KENT.

SOMERHILL, THE SEAT OF JULIAN GOLDSMID, ESQ.

Somerhill is distant about one mile and a half south-east of Tonbridge, situated, as its name implies, upon a considerably elevated position, and it commands a variety of views over a vast extent of country. Viewing the mansion from the southern corner of the principal terrace, two sides of the noble building stand out boldly, and produce a most imposing effect. This is one of those old baronial residences that, with the exception of Knowle, is second to none in the county. The grounds are entered by a handsomely designed lodge, quite in character with the residence, and as we follow the neatly-kept drive, a short distance further on to the left is another very pretty lodge, also in good keeping with the main features of the place. Opposite to this lodge is a rustic boat-house, and a fine expanse of water; and as we make our way towards the mansion, by a path pointing as the most direct way, we find the agreeable shade of a well-timbered portion of the grounds most acceptable, as it not only affords us shade, but it gives to the place a character of grandeur and stateliness, as many of the trees on this spot bear evident signs of having battled with the winds and the storms for some centuries past. Upon the lawn contiguous to the house are some noble cedars, and a few majestic specimens of various varieties of coniferae, while the views from here are amongst the richest in the neighbourhood, being beautifully diversified by hill and dale.

It is not without some amount of regret I now remember that my visit to this place in June last was a hurried one, owing to my wishing to reach the western part of the county early in the day; therefore Mr. Hopgood, the able and intelligent gardener there, will, I hope, excuse me if he should find I have omitted objects I ought to have named, as my notes do not furnish me with sufficient data to go into more minute details of this portion of the grounds; but this is in great part atoned for by the rich treat I enjoyed when inspecting the plant and fruit houses, and in observing the order and neatness that prevailed in every department of the garden.

The first glass structures we enter are two span-roofed houses, one of which is used as a cool plant-house, and the other as a stove. In the first of these we find many very useful plants. It was gay with geraniums, ericas, epacris, and azaleas, and other choice spring-flowering subjects. But besides these, I made special note of a few others in both houses. Amongst the most striking features, there were some excellent plants of the *Coleus Verschaffeltii*, grown in the pyramid style. These are admirable subjects when distributed amongst such decorative plants as ferns, begonias, &c. The plants under notice were pictures of health and skilful cultivation. Then there was *Hoya Cunninghamii*, a very chaste and free-flowering variety for a stove, and when trained to neat sticks, as it was here, makes a fine specimen. That noble fern *Hypolepis repens* was a grand sight, with its graceful fronds towering up so stout and strong, as also was a very large plant of *Adiantum cucucatum*, in a most thriving condition, and *Adiantum*

cardioclana, very fine. Here I saw that very old favourite berry-bearing greenhouse plant, *Rivina humilis*, so useful for Christmas decorations. Of the many valuable creepers grown here, I made note of the following: *Tecoma Australis*, a grand winter-flowering plant, very useful for cutting (this is the white variety); *Passiflora princeps*, with long racemes of drooping flower-spikes eighteen inches long, with no less than nine to twelve flowers to expand upon each raceme; this is, in my opinion, the best of all the Passifloras. On the day of my visit the first flowers were just opening; it flowers upon the old wood. Besides these, I noticed *Begonia fuchsoides*, and that very old subject *Plumbago capensis*.

We next enter a range of houses ninety feet long, in three divisions, including a peach-house, muscat-house, and early vinery; the peach-house was newly planted. Here were some handsome specimens of young fuchsias from autumn-struck cuttings, in a most luxuriant condition. The muscat-house, like the preceding, being newly planted, we have only to notice the

order and good keeping; and when we find them in such a condition, we always accept it as the key to a right understanding of the order and neatness that is sure to prevail in all parts of the garden, and in this the old adage was no exception to the general rule.

In a well fitted up fruit-room I observed, in fine preservation, excellent samples of such apples as the Golden Knob, the Northern Greening, and the Winter Quoining. In an adjoining shed to this is the mushroom-house, a sketch of the interior of which I give here, showing the principal line of beds. There is nothing new in the principle of construction, but it is the material with which it is built that I would call particular attention to, as the foundations for the beds are built entirely of brick-work. This house, as well as the fruit-room, potting-shed, and stoker, are in a line on the north side of the wall of a range of three houses. Now as to the superiority of brick-work over wood-work for the interior of a mushroom-house, every gardener who knows what it is to grow mushrooms in contact with wood,

GROUND PLAN OF MUSHROOM HOUSE AT SOMERHILL, KENT.

promising condition of the permanent occupants of both houses. In the early vinery we found an excellent crop of grapes, with every prospect of finishing well; and considering that the vines are very old, we should consider it quite a success. This, like the two preceding houses, is to be furnished with a young stock of vines as soon as other houses, which we shall presently notice, are in a fit condition to take their place; the able gardener there acting on the wise principle of retaining some of the old vines until others can be brought into bearing. This is a far better practice than rooting all out at one time, and leaving the proprietor's table unsupplied with grapes for two or three years. The next range is a hundred feet long, and divided into a second vinery, and two late ones. In the first division, used as a second house, the crop was very regularly placed, and altogether a degree of healthiness maintained that would satisfy the most experienced grape-grower. In the two later houses there was the same cheering prospect of a crop, although in one instance the vines were very old, but had the character of

must acknowledge that brick is in every way better adapted for it, to say nothing of the durability of bricks as against wood. We have another good reason for advocating the use of bricks, because wood affords such an inducement for the lodgment of insects, especially that pest of the mushroom-house, the wood-louse. I consider the introduction of brick-work into a mushroom-house in the place of wood a step in the right direction, as one likely to reduce the troubles of the gardener and increase the supply to the proprietor's table. Mr. Hoppood would do me and the readers generally a great service if he would kindly inform us by what routine of management he has succeeded so well with this house, as at the time of my visit the supply was plentiful. The figures on the ground-plan denote the positions of the bottom beds, over all of which is a long top bed, as shown on section.

In the kitchen garden everything was looking in a thriving condition, but peas generally are not up to the average point of earliness this season in this county. Upon the walls I noticed marvellous crops of Bigarreau and May

MUSHROOM HOUSE AT SOMERHILL, KENT.

finishing well. In one of these houses we noticed a fine lot of begonias in a most vigorous condition, and also that very old favourite aster-like plant, *Agathaea celestis variegata*, which makes a nice edging for a small bed. In two ranges of well-constructed pits, there were superb crops of both early and late cucumbers and melons in abundance, as well as early potatoes. All these pits in the first part of the season are filled with potatoes, the cucumbers and melons taking their place. Amongst large quantities of bedding plants in excellent condition, I made note of that useful variegated geranium *Lady Plymouth*, well adapted for an edging. The plants were large and in sufficient numbers to be useful. There was also the *Cloth-of-Gold* geranium, a rather scarce article in this county, yet, when properly used in conjunction with suitable subjects, it is a fine addition to any stock of bedding plants.

The admirable arrangement of all the outbuildings about this place, and their superior order of keeping, is worthy of a special remark, as it is not in every place we see potting-sheds, tool-sheds, and stokeries, in uniform

Duke cherries, and also the appearance of a heavy supply of Morellos; both peaches and nectarines had also set a magnificent lot of fruit, and out-door strawberries and other fruits were promising well.

In preparing my notes I was so pressed for time and space that I had not the opportunity of thanking those who with every courtesy and good-will assisted me so much by giving me permission to inspect the gardens under their charge, and by affording me all the information that was in their power; but my thanks are none the less sincere for not appearing in their proper place, and I would take this opportunity to remark that my tour through Kent will be long remembered by me as exemplifying the truth of the old adage in the most unmistakable manner—that of all men the noble brotherhood of gardeners are the most communicative and unreserved class of men we meet with, to say nothing of their individual kindness to a stranger of the craft. This concludes my series of "Notes of a Tour through Kent."
J. C. CLARKE.

BARHAM GARDEN, KENT.

Many of our readers have been entertained, and we trust not a few have been able to glean information here and there, from the remarks upon public and private gardens which have appeared in these pages from time to time, derived from personal inspection. It is now our pleasant duty to give the result of a visit we lately paid to the garden of the Rev. Charles Oxenden, rector of Barham, Kent.

Barham is a well-to-do village in one of the prettiest parts of Kent, surrounded by hop-gardens and corn-fields. It is situated somewhere between Canterbury and Dover, and is three and a half miles from the Adisham station of the London, Chatham, and Dover Railway. It is a pleasant drive from either of the places mentioned, and numerous visitors avail themselves of the kindness of the rev. gentleman, who, with the generosity of a true lover of a garden, allows his neighbours and the public to participate in the enjoyment of that from which he himself derives so much pleasure. A placard at Adisham station and another on the garden gate inform strangers that they can be admitted to see the garden every day except Sunday, between one and five o'clock.

It is our intention on the present occasion to confine our remarks to the flower-garden, and the system of bedding-out, which though necessarily on a limited scale—from 35,000 to 40,000 plants being used in the various designs—is carried out to great perfection. The chief points of excellence are design and colouring, with general good growth of the plant; in all which particulars it will bear favourable comparison with any other garden, whether public or private, with which we are acquainted. The *coup-d'œil* from the study window, the point from which we first saw the garden, is surprisingly beautiful; indeed, we could not help exclaiming upon seeing it, "How very lovely!" and we think there are few, even among those who profess not to admire the bedding system, who could help paying it a similar tribute. The harmony of colouring is so good, that although the general appearance is very brilliant, the eye rests upon it without fatigue. This is owing perhaps in a great measure to the unusually large proportion of *Cerastium tomentosum* in the various compositions, the beautiful gray-white tint of which serves to enliven the whole, while at the same time it tones down and blends all the colours with which it comes in contact. The only imperfection of any moment is in those designs in which the *Coleus Verschaffeltii* enters; the severe cold nights we have had this summer having starved it to such an extent that it has made scarcely any growth, and has therefore not quite filled up the spaces allotted to it; but the rest of the plants are in such excellent condition that, if one were to judge from them only, it would be difficult to tell that the present season has been at all unfavourable.

Another circumstance which cannot fail to strike the observer, is that the outlines of all the designs are sharp and well defined, the minutest particulars of the most intricate patterns being seen to advantage from any part of the garden. This is the more remarkable, because most persons must have felt when looking at a large panel-bed, that the different heights of the various plants which form the whole combination do to a certain extent spoil the effect, as the higher ones must of necessity hide portions of those next them; it being only at a considerable elevation that the design can be seen in all its integrity. But this is not the case in the present instance, for Mr. Oxenden has managed to make the plants in each pattern bloom at one general level, so that the design can be seen almost as well while standing on the lawn, as when mounted on the rostrum which has been erected on one side of the garden, as a *point d'observation* for the convenience of visitors. The simple and ingenious method by which this is accomplished we will now proceed to explain.

The whole secret consists in planting in trenches. Suppose, for instance, we are about to plant a panel-bed. We take the *Cerastium* and plant it on the dead level in the part it is to occupy, and desire so to manage our other materials that they shall all flower on a level with it. For this purpose the earth is removed from that portion of the bed in which the *Calceolarias* are to be placed to a depth of about ten inches, and is carried right away; after which the *Calceolarias* are planted in the trench in the ordinary manner. The same plan is adopted with the rest of the plants—*Geraniums*, *Tropaeolums*, *Verbenas*, &c.—the depth of the trenches varying from ten inches to three inches, according to the height and habit of the plants being dealt with. Of course this system involves a great deal more labour than the ordinary method, and when first done is somewhat unsightly, though not to such an extent as may be imagined; but when the plants are in bloom the great advantage of the plan is seen, Mr. Oxenden having managed so well that the whole of the plants in the design have blossomed at one general level, just above the box edging. The same treatment is adopted with equal advantage on slopes. After

LAWN AND FLOWER BEDS BARHAM GARDEN, KENT.

Scale, 1-20th of an inch to 1 foot.

the bed has been sloped to the desired angle, portions of the earth are removed in the same manner, to suit the requirements of the case. When this system was first suggested to some leading nurserymen, it was "pooh poohed" and said to be ridiculous; but as it has now been carried out here for four years, and has answered every expectation, its success may be looked upon as established, and we ourselves can testify that the examples we saw were all that can be desired.

A reference to the annexed plan will enable our readers to understand our description of the beds, and to form their own estimate of the general merit of the design of the garden; but it must be seen in order to appreciate fully the excellence of the colouring and the extreme neatness with which the whole is kept. The sloping border at the extreme end of the garden furthest from the house (marked A on the plan) is remarkably good. It is 142 feet long with a general breadth of 12 feet. In the front are two rows of *Geranium Mrs. Pollock* and *Lobelia splendens magniflora* planted alternately. Next are three rows of two-year old plants of *Geranium Cloth-of-Gold*, behind which are semicircles of *Coleus Verschaffeltii* on a carpet of *Centaurea ragusina*; at the back is one row of *Gladiolus Breuchleyensis*. The chain bed B is also a sloping border 137 feet long by 7 feet broad. The chain consists of a double row of *Coleus* separating to form the circular links, which are *Calecolaria floribunda*. On each side of the chain is a carpet of *Cerastium tomentosum*, and at the back of the bed a good row of *Geranium Trencham Rose*. At 5 is a fine block of *Stella Geranium* spotted with *Centaurea argentea plumosa*. This bed was not in perfection when we saw it, as the *Coleus* had not grown sufficiently to fill out all the space it was intended to occupy; but this was the fault of the unkind season and not of the planting.

At C is a circular bed of great beauty. It is fifteen feet in diameter; in the centre is a single plant of *Centaurea compacta* surrounded by a three-foot ring of *Verbena Leab*. Outside this is a three-foot carpet of *Cerastium*, bounded by a box edging and a narrow border of yellow spar. This bed is so chaste and so pretty that it seems to increase in loveliness the more it is looked at. D is an oblong bed 15 feet by 8 feet. 1 is an oval centre of *Lobelia Paxtonii*, round which is a frame of *Mrs. Pollock*; the rest of the bed is filled in with *Verbena Purple King*, having specimen plants of *Flower of Spring Geranium* in the corners, the whole being bordered by a narrow path of dark granite. E is a very brilliant and remarkably pretty round bed, fifteen feet in diameter. In the centre is a single plant of *Centaurea compacta*, the upper triangle is a brilliant scarlet verberna, and the corners of the under triangle a seedling *Geranium* raised on the place, which is to be called *Standard Gold*. It is of dwarf compact habit with a leaf of pure yellow without any green blotch in the centre, and will no doubt prove a great acquisition. The circle is filled in with a *Cerastium* carpet surrounded by a yellow spar border and a box edging. We may as well mention here that Mr. Shrubsole, the gardener, showed us seedlings of various plants, some of which are of such excellence that we cannot pass them by without particular mention. One seedling miniature *Lobelia* is exceedingly good; it has exactly the foliage and compact habit of *Mrs. Murphy*, with light blue flowers, a profuse and constant bloomer. A seedling zonal geranium with white-edged leaves possessing many desirable qualities, and is a decided beat upon "Bijou." It is of dwarf habit, the leaf being perfectly flat without the least disposition to cup. The white margin is very broad, occupying about five-sixths of the entire leaf, and is a pure milk-white, in fact about three shades whiter than any we have yet seen. It is to be called the *Bride of Barham*, and if its constitution proves good, will no doubt become very valuable.

The bed at F, which is 22 feet long by 7 wide, is pretty, but not in our opinion such a decided success as most of the others. The centre is of *Geranium Diadem*, with a narrow margin of *Golden Chain*, which is not allowed to bloom. G is a sloping border separating the kitchen garden from the flower garden, and consists of, first, a double row of geranium *Amy Hogg*, behind which is a double row of *Bijou* (bloomless), and at the back a double row of *Magenta*.

The Spar Panel bed H is particularly excellent, and shows the peculiar merit of the plan of planting in trenches better than any other bed in the garden. The colours have been selected with great taste and judgment, and the planting is unexceptionable. All the plants bloom (as we have observed before) on a dead level, enabling the observer to see the whole beauty of the outlines from any point at which he may be standing. The bed is 78 feet long by 15 feet broad, the scrolls being imbedded in a fine carpet of *Oralis corniculata*, the beautiful bronze tint of which harmonizes well with the whole of the colours. A box edging with a frame of cockle-shells surrounds this, and the configuring paths of variously-coloured spar and granite are remarkably pretty and neat. The arrangement of the plants is as follows: 1. *Verbena Crimson King*, spotted with *Cineraria maritima*. 2. *Calecolaria floribunda*. 3. *Verbena Queen of Scots*, edged with *Lobelia Mrs. Murphy*. 4. *Verbena Isa Eckford*, spotted with *Flower of Spring* (bloomless). 5. *Verbena John Keyes*, spotted with *Centaurea compacta*. 6. *V. Beauty supreme*, edged with *L. Mrs. Murphy*. 7. *V. Ariosto Improved*, spotted with *Flower of Spring* (bloomless). 8. *Tropaeolum compactum*. 9. *V. King of Bedders*, spotted with *C. maritima*. 10. All the centre circles are *G. Mrs. Pollock*. 11. *Oralis corniculata* carpet, and 12. Cockle-shell frame.

The superb circular bed at I is by far the most beautiful bed in the whole garden; it would indeed be difficult to find a finer example of brilliant colouring combined with good taste and quiet chaste beauty than this. In the centre is a white vase on pedestal planted with *Stella Geranium* and *L. Paxtonii*. Round this (2) is a three-foot ring of *Tropaeolum compactum*, which is surrounded in its turn (3) by a two-foot ring of *Verbena Celestial Blue*. Next to this (4) is a broad ring four feet six inches wide of *F. melindres splendens*, spotted with *Centaurea compacta*, and round this (5) a narrow circle of *Lady Plymouth Geranium*, which is bloomless. The next ring is divided into triangles, alternately planted with (6) *Lobelia speciosa* and (7) *Cerastium tomentosum*; the *Lobelia* triangles radiating outwards, and the others pointing towards the centre of the bed. The outside ring of this charming bed consists of an edging of *Variegated Arabis alpina* and *Lobelia Paxtonii* planted alternately. The narrow border next the house (L) is filled with *Christine Geranium*, and at K is a fine bank of mixed varieties.

In conclusion, we advise those of our readers who have or can make an opportunity, to visit Barham and judge for themselves; assuring them that they will meet with a hearty welcome from the reverend proprietor, and will be amply repaid for the time they will have spent.

JAMES GOLDWELLS.

SUBSCRIBERS TO THE GARDENER'S MAGAZINE who desire to extend its sphere of usefulness, and are willing to interest themselves in promoting its still wider circulation, can materially further this object by sending to the publisher the names and addresses of persons they think are likely to become subscribers, who will forward to each a SETTER COPY free. A stamp must accompany each name and address sent, to cover the postage of the specimen copy.

THE MOUNTAIN FARM.

After having travelled to and fro some two thousand miles within the boundaries of this tight little island this season, I begin to think the happiest hours that o'er I spent were spent upon a mountain farm. It lies—let's see—a goodish way off from my home: the exact latitude and longitude I don't know, but can work out the figures with very little trouble, or perhaps nearly hit the mark by the aid of a map. It is in a shire of course, and about twenty miles from the roar of the Atlantic, which can be heard at times on still nights, after strong gales, moaning, moaning like some one in pain, and at other times, in bright breezy weather, like some one singing. It is truly a mountain farm, though not exactly on a mountain; it is, in fact, the centre of a great plateau some fifteen hundred feet or so above the level of the sea; so I judge by what I saw of the barometer while there; exact measurement, by comparing our respective aneroid readings, some day to be made when the cool weather comes and we can mutually play at arithmetic. My off-hand rule for guessing at altitudes is to allow one thousand feet for one inch of average depression below the average of the sea-level, a rule sufficient for guess-work and no more. The name of my friend—and a good old friend of the most constant sort he is too—is for present purposes Lesete, and a very proper name, for he has a double share of warmth in his heart, and can melt ice instantly by looking at it. The rainfall is large, 90 inches at the least, and mountain mists and occasional small showers of drizzle are common even in the brightest weather, and with a steady barometer. The temperature is equable; but the London blood in me suggested it was a rather cold place during the brightest days in the month of August, and I quite shivered, though not thinly clad, during a midnight ride I had with Lesete after a visit to a romantic glen a long way off, where we tasted mountain fare, and found that wit and wisdom were not of necessity in populous cities pent, or the products solely of all-arrogant London. But, on the other hand, it is never severely cold in winter. When we wretched cackneys are frozen out the streams here are all flowing; they have, however, every year about eight months of very mild winter. The land is moorland, all moorland. For miles and miles around nothing else than moorland, and every view from this high table-land terminates in a wavy horizon of mountains and moors, some dusky green, and gray, and tawny, showing that man has made the moor to blossom like the rose in many kinds of useful cultivation, some towering into bold peaks and promontories black as ink under a cloudy sky, but in full sunshine showing streaks of a hazy purple, telling that heather only—unprofitable heather, good for grouse, but for man the emblem of starvation—is the principal product of these mountain wastes. Magnificent indeed are the views; they change and change again as we drive over the hills, and have around us on every hand a wondrous panorama of gigantic slopes cutting all the points of the compass, as if nature had been busy churning, and had been suddenly arrested in her work by some freak to leave off mountain-making to try her skill in the fashioning of wild flowers. Greater changes still in going through the valleys. There small villages, very small ones too, nestle amongst elms and alders, all of the trees stunted by the poverty of the land, yet found only in the lowest spots, and following faithfully the devious lines of the brawling strout streams that make music wherever they go, bearing pretty sing-song messages from the mountains to the sea, the burden of their melodies being, "The earth is the Lord's, and the fulness thereof." In the foreground, whether on hill or in valley, vast sheets of heather, alternating with waving eorn, great patches of furze that long before the 1st of September compel one to think about fowling-pieces and powder and shot. All the roadsides flanked by vast breadths of hummocky furze and heather (*Erica tetralix*, the showiest of all our British species) mostly mingled together,—such a display of cheap "bedding" as almost makes one wish geraniums were not. As to the soil, peat prevails, and there are hundreds of acres consisting of a top crust of peaty sponge, varying from a few inches to ten or twelve feet deep. But there are vast tracts of a poor friable loam mixed with stone, the stone a shale in plate-like masses about half an inch thick and of all shapes and sizes, the natural break-up of the vast under-stratum of rock which constitutes the bony structure of the hills for miles and miles around. Some of the narrow roads—they are all narrow, and when two carts pass, one of the two has to draw aside carefully and stand hard against the wall of furze or heather to prevent a collision—some of the narrow roads are cut through the living rock; and the red and gray lines of the tilted strata, hewn sometimes into fantastic scarps and hollows, contrast grandly with the dark greu and glittering gold of the flowering furze, and the dazzling purple of the heather. Sometimes we drive for many miles through fringes of rosy lychnis (*Lychnis dioica*), and there are great patches of the lovely blue vetch (*Vicia cracca*), and sometimes intensely coloured blotches of common red clover (*Trifolium repens*), and the grayish pink valerian (*Valeriana officinalis*), and everywhere more or less of rushes, festucas, osmundas, lastreas, blechnums, brakes, poly-podies, lady ferns, equisetums, wild thyme, bird's-foot trefoil, lythrum, and many another bright and graceful wilding asking not the care of man. The mountain larks sing merrily, the curlew pipes in peace, the lean cattle and the mountain sheep crop the scant herbage, and the idea of a poor paradise appears to be perfectly embodied in the happy faces of the thinly-scattered people, and the beautiful but unproductive hills on which they have built their mud cottages and planted their reluctant yielding farms. Let me try, in imitation of Tupper, to wind up this introduction, and then proceed to other matters.

The mountain farm is as a mine of wealth,
If we can dispense with common luxuries,
And subsist on beauty as our highest good.
The wild flowers are the mountain's garland,
The bees and birds its unpaid choir;
The wild deer, rabbit, hare, and partridge,
Its ministers of innocence and happiness,
That teach the stranger man to be content,
And tune his heart to peace and merriment,
With simple things of humblest origin;
And, in the midst of Nature's vastness,
Own his own littleness and helplessness,
And patiently submit to the all-wise decrees
Of the Maker of the mountains, the Master of the World.

Friend Lesete is a man of whim; that's why I like him. Five years ago he took the farm. I haven't measured it, nor have I put him on oath as to its extent; but call it a thousand acres, more a less; it cannot matter as to a few inches either way to any of us. It was then all moor, and much of it would have ruined a mountain farmer of the district at a rent of sixpence per acre. Lesete was once a great gardener, and all men—that is, wise and good men—know his name, which in the parish books—I don't know the extent of the parish, but a mountain or two is not of much consequence there—in the parish books it is not Lesete, but some other name. Guess it if you like; I shall never divulge, for he desires to be not

to fortune, but to fame unknown. Not to fortune, no, for he is looking after that, and will some day, I am quite sure, extract from the peat, and the poor loam, and the stone, and the clay—I forgot the clay; every lump turned up by the grafting-tool hardens in the sun to a flint-like brick in a few days; such clay!—he will extract from these a fortune of some sort, and for the present is doing well enough, as his happy sunburnt face, his wife's happy and not sunburnt but yet rosy-with-health face, and his children's happy and quite-brown-with-sunburn faces, tell sufficiently, without a word about the tender chickens, and the good beef and mutton, and the cream (oh, the cream!), that he scratches and scrapes and quarries (as it were) out of the mountain farm. "Quarries" I said, and the term is not apocryphal, for he began with deep draining to take off the subterranean water. Every deep drain he made added to the total of the trout streams. The fields are all divided by thick hedge-rows of alder, hazel, blackthorn, and bramble—none of your close-shaven-faced, Romish-priest physiognomy farms is this, giving license to the blast to tear the fleeces off the sheep, and hurl the beeves into the brawling burn, but sheltered wherever and however shelter can be got, and shelter it needs; and the hedge-rows are like burning Newcastle coals to warm the air and nurse the tender herb when the winds pipe roughly. Wherever a dividing hedge-row runs, there runs or jumps or dances or spins a silvery trout-stream; the trout in myriads, and of all sizes, from that of a minnow to the fore-arm of a strong man,—the water, of course, as unsullied as virtue, or trout would not live in it—and at every yard of its course tumbling over stones in a downward but not degrading path towards the ocean, singing always:—

Gaily I sing as downward I go;
Water was made to tumble and flow;
The light of the heaven shines clear on my face,
And while seeming to lose it I'm winning the race.
If you want a sweet sip, stoop down with your lip;
The time will soon come when I'll play with a ship.
If trout are my people in this merry motion,
I shall soon sport with whales in tumultuous commotion.

The work began with deep draining, and the first effect was to render it possible to grow oats. Capital yield of oats, too; I saw some carried on Thursday, thrashed by machine on Friday, and sold at—ah, you want to catch me!—at Whatsitname market on Saturday, when the price was tip-top high, and the quickness of the movement made a difference to Lesete of about two pounds an acre above and beyond what he would have obtained had he waited another week. So you see he is not above making his fortune, if only Fortune will heiferd him.

The next step was to shallow drain and experiment with manures. Now the land poured out its surface water, and the trout streams increased in volume and hurry, and their treble chime changed to tenor and bass, a glorious mountain song. He felt so confident that lime would correct the acidity of the peat, that he carted lime fifteen miles at an awful price in men and teams. But it was not well. Wheat, harley, and turnips lived, but scarcely paid for all the outlay. He tried gypsum, guano, wool—all sorts of things, paying for them like gold-dust; but the returns were poor. Yet the tilling did the land good. Many a hard pan was broken up, the peat began to mellow, the clay bricks which lined the field where the drains were laid began to soften—such mountain dews and frequent drizzle would soften a stone in time, and, indeed, the native rock is ever crumbling into dust, and it is of disintegrated rock the poor loam consists, waiting to be fertilized. The thought struck him as by an inspiration, "The starving farmers here for centuries have been rearing sheep and cattle, and sending them away. On the bog grasses, the narthecium, the fluviatile poa, the whin, the ling, and the wild thyme, the mountain herds have fed and have walked off, taking with them their bones, and the soil wants all the bones back again!" So he thought none, had it consigned from London by railway, carted it a day's journey from the station—two day's journey for every load—and thus began to return to the land the bones of which it had been robbed for centuries. Presto! wheat began to pay, turnips made big hulbs, clover and good feeding grasses became possible. More bone and more bone, and bravo for Lawson's grass-seeds. More drainage, more trout streams, more bone, more grass-seeds. The scene is changed: great harvests of peas and beans, great harvests of wheat, oats, harley, and mustard. Sweet hay in plenty, clover, fat rape, turnips, and mustard for green food. More drains, more bones, more sheep and cattle, more money, junkets, clotted cream (hroma! hroma!), and jolly old wi—; but no, I am ignorant of the extent of pantry and cellar, and only know that, like the justice's belly in the "seven ages," they must be "well lined." Lesete, loving the country and his country's work all the while like a poet, has already made land that starved its former tillers at sixpence an acre worth at least five pounds an acre, and the capital hurried in the soil pays twenty per cent—

Twenty per cent, twenty per cent.,
That's a good rate when money's well lent.

The farm might have employed a dozen hinds in times gone by. It now employs a hundred hands, and hands are better than hinds to a man who converts a field into a workshop, and regards nature as a great crucible into which to toss the rough ore, in the full expectation of taking out a lump of gold.

The mountain sheep are giving place to breeds that weigh them down in the scale; the mountain cattle are retiring before monsters of meat; yet there is much to be done. We went over some of the undrained hogs, all springing now like luxurious couches spread for the great gods, but soon, with the autumnal rains, to become sappy sponges on which no human foot dare tread. There we found the hog pimpernel (*Anagallis tenella*), lovely gem for Flora's tiara, and which she must soon on this spot exchange for *Trifolium incarnatum*, or the green and coarse-looking but fine feeding *Dactylis glomerata*, which Lesete used to grow (in a variegated state) as a grand ribbon plant in days of lang syne. We found the *Potamogeton fluitans*. Can the soil be good for farming where that grows in plenty? No. We found *Sphagnum* and *Drosera rotundifolia* and *Narthecium ossifragum*—acres of them all, and high up on the hummocks between them *Viola palustris* and *Myosotis palustris* in gigantic knolls. Can the land be good for farming where these are the rampant growth? No, no, no! In a short while hence there will be grand crops of oats, wheat, turnips, and grasses, where these now rejoice, and court the dryads to sing of god Pan and the happy days of Saturn to them in the indigo mist that bathes them with balmy moisture all the long year through. The scene has changed and will change; the poor paradise is changing to a fat paradise, and out of the spongy peat and the flinty clay and the irrepressible stone will come forth fun for the thrashing machine, wages for the honest labourer, and good cheer for the children of men. Drainage and bone, what queer regenerators! yet these are the agents that are making a green pasture of a hungry mountain top, and filling the valleys with the bleat of timid sheep and the lowing

of happy herds. Did I say drains and bones? Ah, farther back lies the process; the land, in fact, is blessed with a better regenerator than either, the brain of man is the real fertilizer; and here is a mountain farm made fruitful by means of knowledge, enterprise, prescience, and a great confidence that God helps those who help themselves.

Going over the fields one day with Lesete, I noticed that the common charlock (*Sinapis arvensis*) was a common weed. Many a field, especially if in turnips or mangolds, was gaily golden with this persistent weed. I timidly asked friend L. if he had tried charlock as sheep-feed. I was profoundly staggered when he answered "No." I got the hint of that idea from the Dean of Shipley, so if I appear now to play the part of agricultural prophet, let me at once transfer whatever praise belongs to the character in this connexion to the Dean, who must be lauded against his will, though in his nature modest still. Said I, "Look here, ten acres of swedes, growing nicely, and like cloth-of-gold with the lovely charlock; let's try it." Hard by was a flock of fifty sheep; the spot was far removed from the farm, and we would not go up for a dog. Said I, "You be dog, and I'll be shepherd." Settled at once. L. went up the field, and shouted in a mighty voice, "Go a-forn-'em." The sheep gathered together in a twinkling, and faced all one way, seeing the dog by the aid of their vivid imaginations. "Turn 'em down."—"Go a-forn-'em,"—"round,"—"up,"—"turn 'em down." It was easy work for me. I took the other side, and we had the sheep out like turning a water-wheel, and, with a little opening of gates, and heading up the stony lane to prevent a run towards the moor, got them into the turnip-field. Next morning we had a look. Half the field was spoilt of its golden livery; the sheep were eating in a geometrical order in regular squares, and we observed that scarce a turnip was touched. They pitched dead among the charlock, eating it to the ground, and, if a turnip was nibbled, it was by accident. Or rather, to be more particular, we found by observation that one old ewe, and only one, would touch the turnips, but all the rest ate charlock only. So we used the sheep as weeding-machines, taking them out of the field the moment the charlock was gone, because, of course, at that juncture there would be nothing left for them but the turnips. The flock went thus from field to field, delighted to eat the yellow weed, and caring for nothing else while charlock could be got; and we agreed that so many days' feed—it matters not how many, the measure of the weed will any day give it—might be gained at the cost simply of moving the sheep; a discovery, we may venture to call it, of making weeds into mutton, and keeping the turnips to make beef.

One of the first things that attracted my attention as I roamed about the farm looking for botanical rarities, or gazing abstractedly upon the gigantic hills that rolled around the grey horizon, was the abundance of poultry, large and small. I might have mistaken some of the tawny chickens when far off for partridges, but "Cohh," the pointer, that went about with me for the sake of having somebody to talk to, never pointed at them; and, bless him, he would point at a mouse if he came across one, and look as if his goods had been seized for rent when he found I would not shoot it. Everywhere soher hens and giddy chickies. Far away down by the margin of some brawling burn, there would be seen chickens going to roost, in companies of a dozen or two, in some stunted oak-tree. All over the harvest-fields matronly hens and disobedient chickies, the chanticleers keeping at home mostly, and serving as huggle-calls to prevent a complete distribution of the females and the little ones all over the mountain side. I soon learnt that the way friend L. dealt with his poultry was to let them go where they pleased, let them nest anywhere, give them nothing to eat, make game of them, so to speak, and thus they seemed to spring out of the ground like the wild flowers, and only to need gathering to make one comfortable. "Feed them," said he, "and they won't scratch; leave them alone and they do well, multiply, and get fat on the farm-yard waste." To be sure, the yard swarmed with them, especially about the ricks, and they followed the wains and went far up on the hills, and kept in the track of the carrying of the peas and the oats and wheat, picking up everywhere, like citizens of the world, and ready at any moment to sing, if singing were in their line,—

I have food while others starve,
And beg from door to door.

As to the results, there was no lack of eggs (such eggs, cream and omelette combined). As to chickies, they were as fleshy and as white, as tender, sweet, and digestible, as if taken from some angelic poultry-yard, and, as somebody somewhere said of something,

Too good for nature's daily food.

The somebody was Wordsworth, no doubt, who well knew the glories of a mountain farm, and, for aught I know, may have concocted that line while eating a self-fed chicken in the peace of Rydal. If you want to know how this system answers, I'll tell you one fact. There is an old black hen, half Polish, half Dorking. She makes her nest in the hedge, close home by the farm-yard. She puts in the nest as many eggs as she pleases. She hatches them out in her own time. She nurses them well, and teaches them the way of life, like a professor of scratching. As soon as they can fairly toddle and scratch, she sends them off on a foraging expedition, and there she is again in the nest, in the hedge, on another batch of eggs. As a fancy bird, her value is about ninnepence. Lesete averred that as a breeder of chickens, wholesale and perpetually, he would not take five pounds for her. Nor would I. She should be called the "hybrid perpetual," and I would expect to eat a good chicken of hers every Sunday throughout the year, and get a glass of wine to follow, by stealing a few of her eggs. May the old hen live for ever, and let it not be true what the physiologists say, that the ovum of a hen contains only 650 eggs, and beyond that number she cannot lay one. Bah! old "hybrid perpetual" will lay thousands, I warrant, and as she is mortal, or so it appears, she shall make a decoration for the sitting-room when her family cares are over, and grim Death has put a stop to her motherly "cluck, cluck," that, for the present, tells how well she obeys the injunction of Genesis i. 22.

Geese and ducks are kept on the scratching system, and in considerable numbers. The geese graze on the moors, in the same fashion as on commons everywhere. But they get no corn at night, as is the common rule in country villages. The ducks keep near about the farm, and look out sharp for adventitious extras in the shape of waste grain and scrapings of the pig-trough when the pigs have left it. Tasted several of these ducks; good, of course,—nothing but age or fishiness can interfere with the enjoyable deglutition of a properly cooked duck. But it's another matter with geese, most people like these birds artificially fat. So when we had a mountain goose for dinner, I considered there was a scientific commission sitting—subject for inquiry, quality of an unfed goose. When the commission had finished its agreeable inquiry, a report was drawn up, and agreed to as follows: The poor towns-folk who eat fat geese of the poultener's pattern, or rather eat what is left of them when the heat of the fire has converted

wasted corn into useless grease, are to be pitied with all the tender pity due to such as labour to postpone the gastronomic millennium. Could there be a better goose? Absurd idea! The commission has no more to say about it.

Let me not forget a pretty instrument, by aid of which the farm work is regulated, and, though it is a "catching" climate, showers and fogs occurring suddenly even in the fairest weather, it is most rare that a handful of hay or corn is lost. My private opinion has long been in favour of making it a misdemeanour for farmers to lose hay or corn by bad weather, and here, in a most curious climate, is a simple and forcible illustration of the doctrine. The instrument is a Negretti and Zambra's Aneroid Barometer; my playful friend calls it "Annie Royd," and courts it like a sweetheart. He can tell you for two days to come exactly what will be the weather, and make good forecasts of a week or more. All the while of our stay he told us, long before the showers came, when to expect them, and how long they would last. It was the best bit of barometric practice I have seen as yet. There was a field of peas dead ripe, and the barometer was low. "Never mind," said L.; "cut them." They stood on the field, and were well soaked with rain. "Never mind," said he; "we'll carry them next Tuesday; make the stackyard ready." On Tuesday we looked at them; they were wet, but just hard enough to carry without shelling out. At midday the heavens beamed clear, the sun shone bright and hot, the peas were soon dry, and when the day had nearly gone L. jumped on his horse, galloped over the farm, got the wains, the horses the men, the boys, the girls, all to work merrily, and the peas were home and stacked as if by magic. "There," said the master, "by that quick move at the nick of time I saved the crop. To-morrow and next day we shall have rain again, and, whatever the weather is after that, work will press so hard in all directions, that the peas, if out, might be left till not worth carting. Miss Annie Royd, you've saved me one hundred and fifty pounds."

A very curious occurrence remains fixed in my memory in connexion with this visit. The farm buildings stand all alone in the midst of a wilderness. The nearest post town, which is in reality a village of about twenty houses, is twelve miles distant; the nearest church is sixteen miles away; the nearest railway is a half a day's drive distant, and demanding two changes of horses to do it; there are no neighbours, and one may realize the idea of solitude perfectly without the aid of either Cowper or Byron, who have sung so instructively about "houndless contiguities of shade," and "sitting alone by the deep sea," &c. Well, while enjoying this, so striking a change from the hurried life in London I am used to, the existence of organ-grinders, German hands, howling street vocalists, and other wretches that frequently put a stop to my labours when I am peaceably, and I hope harmlessly, labouring for my daily bread, never occurred to my mind at all. I had clean forgot that the world contained such hideous mortals—such unconverted, demoralized, incurably sinful, selfish, and scottish a set as itinerant musicians of any kind. But lo, as we sat at breakfast one morning, properly disposing of sublime hacon and eggs, there broke out, close under the window, the "tink-a-tink, tink-a-tink" tune of a thing sometimes called a "hurdy-gurdy," but which in reality is a small portable piano. I was immediately seized with such a fit of laughter that I was obliged to quit the table, and go out of doors on the grass, and look at the romantic Italian, and laugh again and again at him and his music, until the fellow began to suspect he had come to a madhouse. The infection spread through the house; we all laughed. Such a thing was never seen before as an organ-grinder of the true London pattern on the mountain-top, perseveringly pursuing his melodious occupation. When the laughing subsided, we enjoyed the music, and when we had had enough of it we sent him away with a liberal reward for the pleasure he had given us, and in full consideration of the fact that he must tramp twelve miles further to find another window, and with all the risk that then he would not be wanted.

I made a pleasant foish of my stay with a little of the noblest sort of sport. We found two noble red stags on the mountain side, and L. and self agreed to hunt them together. We had only bullock dogs to aid us, but one, a powerful hitch, named Nanterose, was equal to the task, and played her part in the chase superbly. Greatly pleased was I to leave L. in the possession of those two red skins; I could not stay so long as to see their meat on the table, but I had tasted of their haunches in imagination while engaged in the rough, hard, but comical chase we had, and in which we and our dogs were the victors. I was sufficiently satisfied to know that there would be meat in the larder at the Mountain Farm after we had left it, for we ate so much that we might have speculated on the capability of the country to keep us longer. Such an appetite as mine would need an average of a stag and a krel of trout per diem, with some small extras, solid and liquid, to make elegant accompaniments. Next time I find my appetite fail I shall fly to the Mountain Farm, and look upon Lesete's steep hills, red stags, and well-filled larder as the perfect cure. TOM TIDDLER.

Calendar.

WORK FOR WEEK COMMENCING SEPTEMBER 21.

Kitchen Garden and Frame Ground.

WINTER SALADINGS.—All kinds of cress may be sown now with advantage to furnish a few nice gatherings before the frost puts a stop to it. *Corn salad* will stand the winter, and furnish acceptable leaves, which must be gathered young. The botanical name of this plant is *Valerianella olitoria*, and it is known in many places as "Lamb's Lettuce." Sow in drills six inches apart. The *Normandy cress* stands the winter well. If sown in August, there need be no further sowing; but if neglected, sow now; and if we do not have very early frosts it will be useful, as when it has got a good root-hold it endures frost with impunity. Another good hardy cress is the *American*; and this is the best substitute for watercress. If a breadth of this was sown in August, it should now be planted out eight inches apart. If none has been sown, get in a pinch of seed at once: this can be gathered from all the winter. It is time now to make another plantation of endive, also to plant out winter lettuces from the seed-bed, and another sowing of lettuces may be made.

ARTICHOKES to be cut down as soon as the heads are gathered.

CABBAGE. Plant out at every opportunity; there is plenty of ground now, and there is good time for the plants to grow.

BROCCOLI.—Plant out all that remain in seed-pans and beds. A good distance is fifteen inches, but in warm sheltered places they may be allowed eighteen inches to two feet.

CELERY will be growing freely after the recent heavy rains. When a

good growth has been made begin to mould up, but not before. Generally speaking, all celery not yet moulded should be commenced, as that begun now will not be fit for use much before November. But in the case of that planted out very late, another week or two may be allowed for growth, as there is not much growth after the earthing process begins.

CARBSICUS AND TOMATOES that ripen tardily may be cut with a portion of stem attached, and hung up in any warm light place. A lean-to greenhouse is about the best place, but a kitchen window will answer, or if laid on tiles in a frame facing the sun, with the lights on, they will soon ripen.

CARDOONS have now done growing, and it is time to blanch them for use. Those that have flower-heads upon them are no use; pull them out. Before earthing tie them loosely, so as to keep the leaves and stems together and prevent the soil going to the hearts, then bank them up high and firm.

CARROTS will not grow much more now, and may as well come up. Store in dry sand in a dry and cool place.

PARSNIPS are still growing, so it would not be well to take them up. But as they are now most delicious when properly cooked, the table may be supplied if desirable. As parsnips stand the winter well, we always leave ours in the ground, and take out a few now and then when wanted; always, however, taking up what remains at the end of February, and storing them in dry sand for use.

TURNIPS must be thinned in good time and the rows hoed between. Where broad-casted, the hoe must do the thinning, weeding, and loosening of the soil; but when in drills it is best to thin them by hand, as the hoe always leaves two or three close together fighting for a place, which is an evil.

ONIONS must be housed, and if not dead ripe, spread them in a dry sunny place, or put them in an oven after the bread is drawn, and let them have a gentle haking. If well dried at once they will keep well, but if stored soft some will rot and some will grow, and all will very soon be worthless.

CAULIFLOWER of the last sowing to be pricked out under hand-glasses, and a few to be potted in 60-sized pots to push on for extra early supply, as they can be planted out early in spring on a warm well-manured border, and have the shelter of old lights, or inverted pots or thatched hurdles, in case of late morning frosts.

Flower Garden.

CALCEOLARIAS.—The time has come for wholesale propagation of this useful hedging plant. There is nothing more easy in all the round of practical work than to raise a stock by means of cuttings. Let the cuttings consist of the shoots of the season that have not flowered, and of which there are plenty now. Make these shoots into lengths of two inches each, removing one or two leaves, so as to have enough bare stem to thrust into the earth; if dibbled an inch deep they will do admirably. The best way to treat them is to make up beds in frames, the beds to consist of mixtures of peat, leaf, thoroughly rotten manure, mellow loam, and sand—in fact, of sweepings and scrapings of the compost yard; or, if there be no compost yard, leaf-mould and light loam, one part each, and one part sharp sand, will answer well. Make the bed level, dibble in the cuttings two inches apart, water them with a fine rose, and put on the lights. They will want no more attention except a little shading for the first two days, if sunny, and air occasionally to prevent mildew. Protect with mats during frost. At the turn of the year they will begin to grow; then take up every other one by finger and thumb, and pot them and place in a greenhouse, leaving the remainder at four inches apart, to grow into neat little plants for bedding out at the end of April or early in May. By this plan you will have two hatches, the plants all strong, and time and tide will tell you what to do with them.

BEDDING PLANTS must be housed as soon as possible. All the old plants of slow-growing kinds of geraniums—such as Golden Chain, Italia Unità, &c., &c.—should be taken up and kept carefully. Many of these beautiful varieties make no effect till the plants are at least three years old.

CARNATIONS not yet potted or planted must be disposed of without any more delay, as it is of great importance to have them well established before winter. When potted, shut them close for a week to promote the formation of the roots.

PINKS to be treated as recommended for carnations.

TULIPS.—Offsets and show varieties may be planted.

AURICULAS to be housed for the winter, and watered very sparingly. Look over the stock in removing them to the frames; see if slugs are hidden in the hole next the crooks; and if the surface of the soil in the pots has moss or liverworts growing on it, you may be sure there is something the matter with the drainage, which see to at once. If aphids are in the hearts of the plants, shake a little dry silver sand over them; then take each plant separately, and hlow the sand out with some force.

BULBS to be potted in successional hatches, so as to prolong the blooming season. Pot the early-blooming *Gladioli*, *Sparaxis*, *Ixias*, *Narcissus bulbocodium*, *Jonquils*, and *Tritonia aurea* in a mixture of peat, leaf-mould, and turfy yellow loam, equal parts.

CHRYSANTHEMUMS require plenty of water, and twice a week manure-water, but not a drop of the latter to touch the leaves. See to any tying that has been neglected. Pot up at once those grown in the open ground for the purpose, or if to be moved to make beds and ribbons, clear the ground, dig it over, and plant them at once in the places where they are to bloom. Plants potted up from the open ground to be kept shaded, and frequently sprinkled till they recover. Of course, they must be lifted with good balls, and be potted firm, with plenty of drainage. Thin the huds of the plants grown for cut blooms. Some of the large incurved varieties give the best bloom from the top huds.

HOLLYHOCKS to be cut down as soon as they cease to be ornamental. If there are good shoots at the base, they may be taken off and potted, and put in frames; they will root in time. Any pods of seed that can be gathered should be put in dry earthen pans, and placed on a top shelf in a sunny greenhouse to perfect their ripening. The seeds are usually damp and soft for some time after they appear ripe, and, unless dried off in some such way as we advise, may become infected with mildew before spring.

REVISI all named plants while there are blooms or fruits to determine if they are tallied correctly. To keep plants correctly tallied will do more to familiarize the mind with their several characters and excellences than any amount of book study; in fact, every garden is a book where not he who runs, but he who stoops, may read; and everything of real interest should have a tally correctly written. This is especially useful in regard to rock plants, coniferous trees, and roses.

DOG'S-TOOTH VIOLET.—This exquisitely beautiful plant, *Erythronium dens-canis*, is not half appreciated as it deserves, and it seems to owe some of its obscurity to the prevalence of a belief that it is difficult to grow. The fact is, the more you do for it the less it likes you. In the front of a pent-

bed is a capital place for them; or in any thoroughly sandy loam. To be well drained is of the greatest importance. They are hardy as oaks, and in the early days of spring their leaves and flowers are alike so beautiful that whoever gives them a fair chance will never after be without them. There are many varieties, but the following are sufficient for all ordinary purposes:—*Album, album major, purpureum, purpureum major, roseum, and Americana*.

ALSTHEMERIA.—These are best known to the old class of gardeners. They are truly fine things, producing many racemes of flowers of brilliant red, orange, rose, and carmine colours, variously barred, and striped. They are generally supposed to be tender, but if properly treated are hardy enough to endure any of our ordinary winters, and may, therefore, be planted with perfect safety. The way to manage them is to plant them in a dry sandy loam or peat, consequently, they are well adapted for beds and borders, which have been prepared for *Calandrinia umbellata* (a lovely herbaceous plant), *Semprevivum, Erythronium, and Tritonias*. A well-drained position, a bed raised above the level, and the shelter of a wall or large mass of shrubs, are conditions favourable to success. In planting, put the tubers nine inches deep, with their bud or crowns uppermost. Leave them untouched several years, and they will become fine specimens, throwing up their flowers freely one to three feet high, and making a splendid display during the summer months. The tallest kinds are *A. aurea*, orange red; *A. pulchella*, scarlet; *A. hemanthus*, vivid red; *A. psittacina*, red and green; *A. Chilensis*, various; *A. Brasiliense*, red; and *A. argentea vittata*, red and yellow: the last grows six feet high, and is rather more tender than the rest, but will do under a warm wall. The dwarfier kinds are *A. odorata rosea*, rose; *A. peleriniana*, red and blush, quite a gem. There is also a white variety of this one, called *alba*, and *A. tricolor*, white, crimson, and yellow.

LILY OF THE VALLEY.—Great is the dismay when a garden refuses to produce flowers of the lovely lily of the valley. And some gardens do refuse, no one knows why. Perhaps bad management is the real key to the failure. It may be planted in any kind of soil or situation, and usually will grow like a weed. If any difficulty is met with in growing this plant in the open ground, prepare for it a piece of deep well-manured loam, plant at any time, but best of all in autumn, and let the roots be only two or three inches deep, and leave them alone. You will, no doubt, be well rewarded. If the little bulbs are put in singly, a foot apart, they will meet by the second season after planting, and flower abundantly. The way to grow it in pots, and to force it for early bloom, has been described in the issue for Feb. 25th, 1865. It may be proper, however, to add that the best roots for forcing are those imported from the Continent by dealers in bulbs—they are larger, and every way better than can usually be grown in English gardens. When grown in pots they come in usefully sometimes for exhibiting, and are charming subjects for the decoration of the greenhouse. Those with variegated leaves should be grown in sandy peat, and kept several years in the same pots, preferring to shift them to larger sizes as the pots are filled to shaking them out, as a certain degree of starvation preserves the beauty of the leaves. The prettiest of these is *Convallaria majalis foliis striatis*, the leaves are elegantly variegated with golden lines. Another is called *Folii marginatis*, having elegantly-variegated margins. There is a pretty double-flowered variety called *flora pleno*, and there is a red-flowered kind called *rubra rosea*, which has a delicate tinge of colour. It makes a change, but it is certainly not more beautiful than the white kind.

CROWN IMPERIAL.—This, the *Fritillaria*, can be grown well in any common border, but the smaller kinds are better adapted for pot culture than the open ground, and they require a sandy peat soil. The common Crown Imperial, *Fritillaria imperialis*, requires a rich, deep, moist loam, such as most herbaceous plants thrive in. In almost every well-kept garden the common soil is good enough for it. It is a noble subject when in flower, and is so much a favourite that the Dutch growers have raised hundreds of varieties. The best of these are, *King of Holland, Maximum, Slageward, Double yellow, and Double red*. There are two charming varieties with variegated leaves; one is *gold variegated*, the other is *silver striped*. These make splendid clumps or beds. The best of the smaller kinds is *F. meleagris*, of which there are several varieties. It is a most beautiful plant. This is well worth growing in pots, but it is quite-hardy, and will do well in the border. The varieties of imperialis grow four feet high; maleagris grows only one foot.

Fruit Garden and Orchard House.

WALL TREES must have *extra care this season*, or there will be no fruit in 1868. The weather has for a long time past been most unfavourable for the ripening of the wood, and the trees are gross and sappy. The safest procedure is to thin the trees regularly, and nail them in so as to expose all the best of the new wood to the light of the sun and the heat of the wall. The shoots laid in should be shortened, which will also assist in the maturation of the fruiting joints, and there is no fear now of a second growth. If the borders are covered with pot plants or rubbish, or planted with winter greens, clear all off, and fork the ground lightly.

APPLES to be gathered during dry fine weather. Those already in store must now be looked over, to remove all that show the first symptoms of decay.

PEARS require same attention as apples.

STRAWBERRY BEDS made this season are looking well; the rains have promoted a free growth. But, as there are plenty of weeds, the hoe must be used, and the weeds must be raked off, and the ground between the plants must then be well trodden.

ORCHARD TREES are now in many instances leafless, and perfectly at rest. Replot such as require it at once; those still full of leaf to be put in the hottest part of the garden, and have no more water till after they have shed their leaves. Any of the trees may now be pruned in; and as work is not generally pressing now, this is a good time to prune, train, tally, and pot and plant new trees for culture under glass.

PLANTING.—The planting season is near at hand, and where alterations and improvements are intended, the preparation of the ground should be begun at once, as there can be no good result from planting trees in ground left untouched till the last moment, and then hastily chopped up and prepared in a superficial manner. It is strange that few people ever think of manuring for trees; yet if to be planted on land that has been much cropped, or where trees have been before, deep digging and manuring are essential to success. Soils deficient of calcareous matter may be greatly improved for all kinds of fruits by a liberal dressing of chalk, lime, or old mortar. Land too wet for fruit trees may be made suitable, if proper drainage cannot be afforded, by laying it up in long banks of six or eight feet wide, with deep waterways between. Many a marsh might be made profitable by this simple procedure.

Greenhouse and Conservatory.

CONSERVATORY AND GREENHOUSE.—The high winds during the past week must have given our readers fair warning that if tender pot-plants are not at

once housed they may very soon not be worth housing. There is nothing more to be gained in the way of hardening; in fact, a little sun-heat under glass will ripen the wood of plants that are still in a sappy condition much more effectually now than sunshine out of doors, besides the safety of glass for whatever is worth keeping. Keep from using fires as long as possible; but if any special reason require it, let no rules without reason interfere; set the fires going, dry the houses, and have a change of air while there is no fear of a chill. By good management, much may be done now with sun-heat. Plants recently potted and housed must be frequently sprinkled, and kept a little close to encourage root-action. Do not keep them very wet at the roots; in fact, after the first watering when potted, let them go nearly dry at the root before watering again, but sprinkled frequently, and as the lower leaves wither remove them. Keep the houses clean and dry, so as to allow of as much ventilation as possible among hard-wooded plants. If the weather is mild and wind westerly, give air at night to *Camellias, Azaleas, Heaths, Epacrises*, and other subjects of like habit and hardiness.

LACHENALIA.—This is one of the easiest of plants to grow well, yet too often we see them with thin, flabby, and perhaps bruised leaves, and a few poor spikes of flowers; they should have leaves an inch or more across, very fleshy, a rich deep green colour, and richly spotted, and half a dozen large spikes of flowers in a five-inch pot from half a dozen bulbs, and a few more spikes rising to succeed the first lot. The best routine of cultivation is as follows: The bulbs are potted as soon as they begin to grow naturally, in a mixture consisting of three parts mellow loam, half a part of thoroughly-decayed hotbed manure, and half a part of silver sand. Six bulbs of the largest size are put in a five-inch pot; all the small ones being potted separately, and rather thickly, to increase in size for the next season. They remain out of doors, and have all the rain that falls, and take their chance like hardy plants until there is actual fear of frost. Then they are removed to a top shelf in a light, airy, cool house, where there is enough hot-water-piping to keep out frost, and no heat is used except in frosty weather. The amount of protection is, in fact, not much more than they would have in a common frame. It is an important matter to keep them always moist, near the glass, with plenty of air, but never to be frozen. Starvation ruins them, and heat is not good for them, though, if forced gently, they flower well. Ours do not bloom usually till the middle of April, and they then make a splendid show. One lot is always used for the outside margin of a circular bed, which is then usually filled with a mixture of tulips, hyacinths, and elegant hardy shrubs—all in pots plunged in cocoa-nut fibre. There are several varieties entered in the catalogues, but *bicolor* and *tricolor* will suffice for all ordinary purposes.

TRITONIAS.—People will persist in confounding tritonias and tritomas, yet they are as distinct as lilies and ixias. Tritonias are not quite hardy, but they may be grown out of doors in a bed of sandy peat well drained, with some protection in winter. The best for out-door purposes is *T. aurea* (sometimes called *Crococoma aurea*). This forms a fine bush-like mass two feet high, well covered all the summer with pretty orange-coloured flowers. To grow it out of doors the bed must be sheltered, and the plants must have a cover of cocoa-nut fibre piled over them all winter. As to pot-culture, all the tritonias can be managed easily. Pot the bulbs in autumn, in well-drained pots of sandy peat. Give very little water until they are growing freely, and keep them in a cool greenhouse or frame, taking care that frost does not get to them. When they begin to grow, give air frequently, and as they advance increase the supplies of water. If extreme neatness is required, they should be neatly tied to thin green stakes, but it is better to let them sprawl about *au naturel*. Put a row of *T. crocata* in bloom, and in the sprawling state, all along the front of the conservatory stage, and what a glorious sight you have! All the species and varieties are good, but we recommend particularly, in addition to the two already named, *T. concolor, T. eximia, T. fenestrata, T. lineata, T. rosa, T. speciosa*.

Stove and Orchid House.

ORCHID HOUSE.—We have several times cautioned our readers against using an excess of heat and moisture at the decline of the season. By withdrawing the supplies of water, orchids will go to rest safely at much lower temperatures than is usually adopted; *Cattleyas* especially must be kept cool now to make them rest.

WINTER FLOWERS must be thought of now or never. Give a few *Begonias* a shift, and push them on for flowering; look to *Euphorbia fulgens* and splendens, *Poinsettia pulcherrima, Achimenes picta, Lily of the Valley*, and pot up from the borders *Dielytra spectabilis* in plenty; it is one the best of things to force, and, though "common," exquisitely beautiful.

Forcing Pit.

PINES ripening their fruit must be kept warm, and have less water. Be careful how you give water now, and keep up the heat in the succession pit.

VINES must be got ripe in the wood now, if they are not so already, or all sorts of evils will befall them. Cut off the ends of any shoots that are green, and any that continue to grow too luxuriantly may be checked by removing all or part of their leaves, at the same time keeping their roots as dry as possible. All superfluous shoots to be removed as soon as possible, and the vines in the early house to be pruned at once, and the border covered to keep it dry and warm; wooden shutters are sometimes used, but we prefer straw hurdles.

THE NEW FUEL.—To burn coal economically, instead of to volatilize 30 per cent. of that which we purchase in the form of smoke, and to send half of the heat produced up the chimneys, has been as yet too hard a task for us to accomplish. Gradual and enlightened reform in a matter of this kind, perhaps of any kind, is not altogether germane to the English character. But when a new feature is introduced, when a new power comes into play, great and salutary improvements often accompany it, as if of their own accord. Such seems to be the promise of the consumption of petroleum. If all that we hear of the economy and convenience of this material as a fuel be true, there can be little doubt that it will rapidly supersede coal for manufacturing, if not for domestic, purposes. In such a case, a smokeless London is not an impossibility. Let our photographers not omit to perpetuate some of the effects of picturesque gloom which, during August, 1867, have shrouded the leeward districts of London as if under perpetual thunder-clouds. The residents in a smokeless London would find it hard to understand how their predecessors should have supported life in the metropolis as it existed during the dog days of the present year; and no photograph can enable those happy future citizens, if such be about to succeed us, to tell how far the chief necessary of human life, the air we breathe, has been poisoned by the improvident development of commercial activity, and by a gradually-accumulated neglect of the prime laws of comfort and of health.—*The Builder*.

Correspondence.

ON THE MERITS OF TRICOLOR GERANIUMS AS BEDDING PLANTS.—All your readers must have had an opportunity of seeing and judging for themselves, either in public or private gardens, beds and edgings and borders, of this beautiful section of geraniums. Gardeners generally esteem them as great favourites, planting them in the most conspicuous beds, in ribbon-borders; and all sorts of colours and tints are brought into requisition for contrasting with them; and many of my neighbours estimate the value of their collection of bedding plants by the number of tricolors they possess, and count all other things of secondary value. Let us look at them without prejudice or favour. Are they worthy of the position they hold? No doubt they are in fashion; but let us not be led by fashion, but by good taste. Have they got that which constitutes a good bedding plant? Does not the colouring which makes the tricolor so beautiful as an individual plant deteriorate it for this purpose? To appreciate the beauty of this, give me a single plant; nay, I could say one single leaf. Concentrating my attention thereon as a lover of nature, I can revel in its loveliness; with the eye of a florist (or leafist) I can recount its numerous qualities, its harmonious blending of colour, its evenness of outline, its rays, its zones, its belts, its splashes, its contrasts, &c.; and as each successive leaf expands, with what eagerness do we watch its development, especially if the plants are seedlings, and if we think we can detect some peculiar tint, some advance in habit or outline! What delight is kindled while it displays to us, in gratitude for our care, all the colours and tints of an autumnal evening! It is as bright, and almost as transient, too; for on each day we look on a leaf it is changed in character, according to its age and development. It is too good a plant to be subordinate. What we want as a bedding plant is one that is decided, or self-colour, in flower or leaf; and the gardener can then use his colours as a painter while painting his picture—the difference being, one is upon canvas, the other on the greensward. Having these colours, we can make the picture as our fancy may dictate. Now, what colour can the artist or gardener call his Mrs. Pollock or Italia Unità? *No colour at all*—a mixture and a muddle; that is, in comparison with such as, say Golden Chain, Golden Fleece, or the bronze-foliage sections. They do not, in my fancy, harmonize with any other plants, although I have seen many things tried with them, and as a rule their own blooms are not bearable. When they are used as bedders, it ought to be in a limited quantity and in isolated beds, where the eye catches no other high colour but its surroundings, such as green cool verdure. I have beds of Mrs. Pollock, but none gives me so much pleasure as one of several varieties of plants I have planted in some rock-work. The beautiful green of ferns as a background and the dark rugged boulders of rock afford pleasing contrasts to the beautiful zones of the tricolor geranium; nor ought we to have large beds or masses of it: a small bed, say four feet over, a space where the eye looking down on it can comprehend the whole. Large beds are, indeed, too much of a good thing. I look on them with some such feeling as a painter would look on an admirable picture, but would not like a room hung full with fac-similes. It may be according to fashion, for I hear ladies on the Continent are wearing dresses on the skirts of which are printed copies of well-known and beautiful landscapes; but doubtless they are eyesores to a landscape painter. It is too much of a good thing, and not good taste; and so I say in the case of the tricolor geraniums.

Tooting Common.

T. S.

AGAVE GEMINIFLORA.—Can any of your numerous readers give me a few hints respecting a plant of the Agave tribe, which I consider to be the *Agave geminiflora*? I have had two of these plants under my care for many years; their foliage was considered ornamental for the conservatory. One of them, in August last, threw up a peculiar-looking fleshy stalk; it grows fast, and is now nearly seven feet high. Within a little distance from the base of the stalk it has thrown out bunches of flower-buds; I can now count over two hundred. I believe the flowering of this plant to be very rare in England, and shall be glad therefore to receive any information as to treatment while in flower, so that I may, if possible, save the plant from death by exhaustion.

JOHN CARTER,

Victoria Road, Wimbledon Park.

Gardener to Alderman Besley.

[We are not acquainted with this species of Agave; is it not rather a *Fouquieria*? We shall be glad to hear from any of our readers experienced in the management of succulents respecting this subject. In the mean time we advise our correspondent to give the plant plenty of water, and to increase the temperature slightly.]

KEEPING BEDDERS IN AN OPEN BORDER.—As a constant subscriber for several years, I should feel obliged by your advice. I have on one side of my garden a long border, facing north-east; it has a wall behind it, and is overhung by large trees in some places. It is of course very dry, especially as the whole garden is on a slope, and I have tried various plants in vain. I should be much obliged by your informing me what would grow best in such a situation, and the best mode of treatment. I observe this week you speak of turf-pits. I kept a large number of calcularias through last winter in a bed under a westerly wall, only protected by a wooden edging all round, about a foot deep, and covered in on top by a double thickness of sugar-mats. I also preserved in cold frames and pits all my stock of bedders, including Pelargoniums, Fuchsias, Lobelias, &c., &c., and had very few losses indeed, except in verbenas. What is the best time to plant bulbs of gladioli for an open air plantation? I see by "Carter's Catalogue," just to hand, they send them out in November.

B. A.

[The dry shaded border might be made beautiful with green and variegated hollies and a selection of herbaceous plants, such as Solomon's Seal, Polyanthus, and Primulas (the double varieties of the English primrose being exquisitely beautiful), *Artemisia maritima*, lesser Celandine, Enchanter's Nightshade, *Doronicum caucasicum*, *Epilobium hirsutum*, *Helleborus niger* and *viridis*, *Myosotis sylvatica*, *Potentilla alba*, reptans, and *tormentilla*; the double yellow Ranunculus or Bachelor's Buttons, *Spiraea Japonica*, *Statice armeria alba*, and alpina, any of the Periwinkles, especially those with variegated leaves, *Viola cornuta*, *cucullata*, and *obliqua*; you may also plant there a few clumps of Roman hyacinth, snowdrop, crocus, and narcissus, and leave them untouched several years. Any of the hardy Japanese shrubs would thrive in the same shady border. If you refer back, you will find abundant information on the cultivation of the gladiolus. The month of April is the usual season for planting the bulbs.]

Replies to Queries.

W. S.—This is not a good time usually to purchase bees, because the winter is approaching. Prices of stocks vary. We have heard that Messrs. Cutbush and Son, of Highgate Nurseries, supply swarms in the season; but we do not know if they also supply established stocks. You might write to them and inquire. The best book on bee-keeping is Taylor's, published by Messrs. Groombridge and Sons, price 4s. We cannot answer your query about savings banks.

W. W. B.—Your petunias are infested with thrip; you have kept them too hot and too dry.

T. Lechmann.—Your plant is *Dracena terminalis*, a rather difficult thing to keep in a window, but you may keep it with care. Read an article on *Dracenas*, by Mr. Gordon, which appeared five weeks ago, and you will learn how to manage it. Keep it warm and rather dry all winter, and let it have as much light as possible.

Q. Z.—Strip off the grapes and destroy them at once; they will come to nothing if left, and will probably do harm. Then begin to remove the leaves from the vines, a few at a time at intervals of a few days. When the vines are quite bare of leaves, wash them with a solution of Gishurst compound.

Hibernia.—1. We do not know; write to the advertisers of the plant. 2. Inquire of an astronomer. 3. There is no such book. 4. *Crocus sativus* has a perianth of six equal segments, three stamens shorter than the corolla, and a three-lobed stigma. *Colchicum autumnale* has six stamens, each alternately longer than the other. There are other and very obvious differences, but these will suffice to distinguish the plants while in flower.

B.—Leave the long gross shoots alone, and when pruning in March next shorten them back to hard wood, so as to retain a dozen or so of the best buds.

B.—"Editor" scarlet geranium has always been spoken of in these pages as first-rate.

Elvira.—Your fuchsias are infested with thrip; they have been kept too dry and too hot.

Forcing Lily of the Valley.—J. M., Liskeard.—The best bulbs for forcing are those imported from Holland, and which you can obtain only from the first-class seedsmen. Pot them as soon as you obtain them in light, rich, sandy soil, and plunge them out of doors as soon as potted in cocoa-nut fibre. In October put them in a warm greenhouse, and after the expiration of a week transfer them to a forcing pit or stove, where the temperature averages 50°, but which must be gradually raised to 70°, by which means they will be in bloom at Christmas. After Christmas they require about four weeks to be brought into bloom in a temperature of 65° to 70°. They must have plenty of light, or they will be poor wiry things. With good bulbs and good management, twenty to forty spikes of bloom may be obtained in a 32-sized pot.

Hamilton Terrace.—You have done all that can be done. Now leave the trees alone till winter, and then have them scrubbed with a hard brush and hot strong brine; that will keep the American blight away for several years, and do the trees much good.

Club.—Working Man has no chance of getting rid of club in his light land unless he will abstain from growing cabbage for two or three years, and in the mean time keep the ground always at work. A good dressing of lime might do very much towards a cure, but it is easier to propose remedies for club than to effect a clearance of the pest.

Growing Specimen Pelargoniums.—Novice must do very little with his plants until March next, but the foundation branches of the specimens must be carefully trained out while they are soft and pliable, otherwise to get them into position when the wood is ripe will cause the breakage of many. Keep them very near the glass; do not stop or prune until February next; winter them as cool and as dry as will be safe.

R. W. S.—The dates of the chrysanthemum shows are not yet determined by the respective committees, except in a very few cases, and therefore it is impossible for us to advertise them.

Correct Label.—We shall not report the Crystal Palace autumn show, for the simple reason that we do not think it worth reporting; the Crystal Palace shows become worse and worse every year, and are now quite unworthy the attention of men who value their time, and who are accustomed to see things well done.

Nemo, Kensington.—Your plant is *Artemisia vulgaris*, the "mugwort" of the village botanists.

CATALOGUES.

HUGH LOW AND CO., CLAPTON, LONDON, N.—*Select List of Dutch Flower Roots suitable for early forcing.* The hyacinths are classified in colours and styles with great care, and with more minuteness of distinction than is commonly observed.

B. J. EDWARDS, 222, STRAND.—*Autumn Catalogue of Hyacinths and other Dutch and Cape Bulbs.* A good list, with supplementary selections of annuals for autumn sowing, and miscellaneous garden requisites.

JAMES CARTER AND CO., HIGH HOLBORN.—*Vade Mecum Part IV.: Dutch and Cape Bulbs.* A great mass of useful information, combined with copious and well-arranged lists of bulbs, stove and greenhouse plants, fruit and ornamental trees, roses, and other subjects in request at this season.

WILLIAM CUTBUSH AND SON, HIGHGATE NURSERIES.—*Bulb Catalogue for 1867.* This catalogue fairly represents this celebrated bulb-growing firm. There is no announcement made as to any exhibition by Messrs. Cutbush and Son in 1868.—*Descriptive Catalogue of Stove and Greenhouse Plants, Fruit Trees, Roses, &c., &c.* Exceedingly neat in appearance, and admirably arranged for easy reference, and moreover including all the good things in the several classes.

HENRY LANE AND SON, GREAT BERKHAMSTEAD, HERTS.—*Fruit Catalogue, 1867.* The fruits are all described briefly as to size, season, character, &c., &c., and the best varieties for small collections and for special purposes are clearly indicated.

JOHN PRASER, LEA BRIDGE ROAD, ESSEX.—*Catalogue of Flower Roots.* A short but good list of hyacinths, tulips, gladiolus, strawberries, and other subjects in demand at the present time.

THOMAS SAMPSON, PRESTON ROAD, YEOVIL.—*Catalogue of Flower Roots.* Short and sweet, lacking nothing good, and not likely to perplex intending purchasers with a bewilderment of varieties in any of the classes.

The Gardener's Magazine.

SATURDAY, SEPTEMBER 28, 1867.

FRUIT-TREE CULTIVATION IN ENGLAND is not in quite so deplorable a state as to demand a revolution as the alternative of its entire abandonment. Our exhibitions keep us constantly reminded that in all parts of the country the best fruits are skilfully treated and thoroughly appreciated, and, generally speaking, we believe sufficient is produced for our own consumption, though our markets are largely supplied with foreign produce. Communications with the Continent are now so rapid and certain, and the cost of freightage is, comparatively speaking, so small, that the foreigner, employing labour at a cheaper rate than rules here, renting land at less than English averages, and with a more intense and continuous flood of sunshine gratis, can compete with our own growers advantageously, and is likely therefore, to a great extent, to keep command of our markets in respect of certain classes of produce. Cheap baskets of well-ripened Black Hamburgs may now be seen in all the grocers' windows in London, and they command a ready sale at a price which pays the grower a liberal profit on the cost of production. Nevertheless, English-grown fruit is by no means at a discount. First-class peaches have been realizing a shilling each at Covent Garden for some time past. First-class English grapes, which surpass in quality all other grapes, no matter where in the world they are produced, realize prices that are calculated to encourage home cultivation of this best of fruits. As to the general management of fruit gardens, our practice is not quite antiquated, and perhaps a little of what might by some be called retrogression would be for our benefit. As to peaches and wall-trees generally, we see them in good gardens superbly managed, and on the fan-shaped system of training and its few modifications, the trees are, in a majority of instances, in perfect health, and are abundantly fruitful. We have two special enemies to contend with—the late frosts that destroy the embryo fruit or nip the blossom in the bud, and the dull damp weather commonly prevailing in autumn, which interferes materially with the perfect ripening of the wood. The antidote to these two evils is to be found in the more general employment of glass. First-rate grapes and peaches can only be obtained, except in highly-favoured districts, with the aid of some kind of shelter, whether in the form of a glass-covered wall, a spacious and well-fitted house, or the more humble, but highly useful, "ground vinery." It is quite certain that the judicious use of glass in fruit culture will always quickly repay its cost, both in the greater certainty and quantity as well as in the superior quality of the produce. We save thereby the tender crop from destruction by frost and wet when the trees are in bloom, we obtain increased heat for the ripening of the fruit, and the growth of the season is more perfectly matured. No one expects a dish of Black Hamburg grapes or Warburton Admirable peaches worth a place on a good table without the help of glass. Even strawberries, the hardest of our choice fruits, and lovers of the fresh air, are the better for the shelter of glass in a cold season. But we can scarcely help saying that in many instances, and with of course the best intentions, glass has been abused. The orchard-house with its potted trees is a charming affair when well managed, and the trees will give as much fruit as would fill the pots they are grown in; but it is a manifest delusion to suppose that the produce is ever equivalent to the actual value of the labour expended in securing it. Where an amateur, seeking amusement and not charging an ideal price to his own fruit account for the hours spent in the care of potted trees, has attained to some degree of skill in this system, it affords a delightful recreation, and the result may be considered to him "all profit." But if skill and labour have to be paid for at average rates, potted trees make too much work for the return they give, and we go back to the old and sound system of planting out in borders as the one to be trusted for profitable ends. In the first instance, fewer trees are required, at every step there is less work, and the trees, having more

vigour of growth, are less infested with vermin, less tortured by disease, and the crop puts to shame that of the best collection of potted trees occupying a similar extent of glass. A well-shaped and freely-fruited pot-tree is a beautiful object, of which its possessor may well be proud; but the man who keeps a ledger, and desires fruit at no higher price than its actual cost in outlay and labour, will be cautious how he deals with these pretty toys, and will prefer to accommodate nature rather than engage in a constant warfare with her. All restrictions of the head and root, no matter what the subject may be, is a form of warfare, and in the case of fruit-trees restriction must increase the cares of the cultivator and lessen the chances of success.

But restriction is not alone practised in the cultivation of fruit-trees in pots. We see it everywhere in operation as the orthodox method of cultivating the grape-vine, and the complaints of shanking, bad colouring, and other ailments, which reach horticultural advisors in extravagant abundance, invariably occur in connexion with restricted vines. The great vines at Finchley, Hampton Court, and Cumberland Lodge are never in need of doctors; they spread abroad as Nature designed the vine to spread, and though subjected to artificial treatment, and rooted in a soil many degrees colder than the vine is accustomed to in its native habitats, their vigour is ever in excess of the influences tending to their injury, and a state of health and productiveness is normal to them. When we called attention to this subject in December last, we had no anticipation of the discussion that would follow; but we had no doubt at all about the result of an inquiry, and now we may fairly assert that the balance of testimony is overwhelming in favour of the unreserved acceptance of the TEACHINGS OF NATURE; and restrictive culture, except for special purposes, and under peculiar circumstances, has received its death-blow.

What is true of the grape-vine is true of other trees. "Miniature fruit gardens" are to a great extent miniature delusions. As in the case of potted trees and single-rod vines, and single-cordon apple and pear trees, the "prolific bushes" are admirable, beautiful, useful things. They grow very little, and produce, in comparison of the space they occupy, very fair supplies of good fruit. But if our supplies of home-grown fruit are defective, these miniature trees will not supply the deficiency. They belong to the land of toys, and their advocacy as profitable fruit producers has been overdone. Let us hope that somebody has been benefited in a substantial manner by the distribution of thousands of these "miniature trees;" but let us hope also that healthy trees on free stocks—trees possessed of vigour and long-lasting properties—may be looked to for profitable results rather than such as are chiefly interesting because of the excessive trouble they occasion, and their general adaptiveness for planting in the front of a doll's house.

THE THOMPSON TESTIMONIAL FUND progresses far too slowly to represent the appreciation of British horticulturists for merit and good service. It may be that testimonials have become so commonplace as to meet with indifference, even in the case of an exceptional claim to public generosity; or it may be, and possibly this is the true reason of the tardy progress of the subscription list, that it is not yet generally known throughout the country that Mr. Thompson is about to retire from the superintendence of the Horticultural Society's garden at Chiswick, and his friends have determined to make him a substantial present in recognition of his splendid services to English horticulture. None of our professional readers need to be reminded of Mr. Thompson's labours in the classification of fruits and the rectification of fruit nomenclature. Except for his labours, more than one recognized work on fruits could possibly never have existed, and it is quite certain that to him chiefly are pomologists indebted for the precision, accuracy, and uniformity of nomenclature and classification that have of late years acquired ascendancy. From his position of authority at Chiswick, Mr. Thompson has exercised a beneficial influence upon every fruit-garden in the land. Through his application, and the exercise of a fine critical power, local names have given place to names universally understood; inferior varieties have been eliminated from the nurseries and the catalogues, and the best kinds in the several classes have been brought into notice prominently, and established as the

standard by which the merits of new varieties shall be tested. Nor is this the only service for which we are indebted to the modest, pains-taking, courteous, and clear-minded superintendent of Chiswick. He has written the best practical treatise on horticulture, "The Gardener's Assistant;" he has enriched the literature of science with papers on meteorology, relative climate, the diseases of plants, the various modes of improving and of multiplying fruits; and for five-and-thirty years he has superintended the meteorological observatory at Chiswick, and accumulated a splendid series of minute observations and returns, which cannot fail to prove of the utmost value in the investigation of atmospheric phenomena, and the determination of meteorological law. We are almost inclined to apologize for obtruding these particulars, because the progress of horticulture during the past half century has been so intimately associated with and dependent upon Mr. Thompson's labours, that to advocate his claims may be really superfluous. Lately, a list of subscriptions to the testimonial was forwarded to us, and it appeared a somewhat scanty list, and we concluded, and still conclude, that it is not yet sufficiently known, that every practitioner of horticulture has the opportunity of testifying, by subscription to the fund, that Robert Thompson of Chiswick has not laboured in vain, and shall not be without his reward.

There is a chronic difficulty in connexion with testimonials, which we should like to see ignored or annihilated in this particular case. This is not strictly a complimentary proceeding. A *substantial money-gift* is intended. We suppose all our readers know what that means. Now, the chronic difficulty is this—persons who cannot subscribe large sums are shy of sending small sums, and in the end do not subscribe at all, though conscious that in abstaining they neglect a duty and lose a pleasure. Now if thousands of gardeners allow this difficulty to paralyze their generous hands, the Thompson Testimonial will lack a feature of inestimable value. The difficulty may be most easily overcome. Let us take it for granted that every gardener in the land desires to contribute according to his means. Let there be established at once in all gardens where several hands are employed, in all nurseries, in all assembly and club rooms where gardeners meet, in all possible centres of horticultural interest, auxiliary funds for the gathering together of shillings, half-crowns, and so on to larger and larger amounts, and within a specified time, say a month, from the commencement of the movement let the moneys be transmitted to THOMAS MOORE, Esq., the Botanic Gardens, Chelsea, or Mr. JAMES RICHARDS, Assistant Secretary to the Royal Horticultural Society, South Kensington. Let there be, for once in the history of horticultural industry and enterprise, a GENERAL CANVASS, head gardeners, foremen, secretaries of societies, and others in influential positions, taking the lead, and that *promptly, generously, with spirit*, and in entire forgetfulness of any and every personal or party feeling, and with the view to make a bright mark on the annals of horticulture in commemoration of Mr. Thompson's long-pursued and honestly-accomplished labours.

AMONGST the many sales taking place just now, one announced for the 2nd and 3rd (Wednesday and Thursday next), at the old Edmonton Nursery, well deserves the attention of all classes of plant-buyers. Speaking by knowledge, we can say that the stock now coming under the hammer is as good as it is various. This sale will, we suppose, be the last scene in the history of one of the most celebrated nurseries on the north side of London.

A NEW FLY-TRAP.—A horticulturist who has had reason to complain of flies has invented a trap for destroying these pests; the trap is exceedingly simple, and is said to be very effective. The inventor commences by stating that to preserve your fruit-trees you must offer the fly something he prefers to your plums; now he likes meat better than anything else, so you place a piece under a cover, leaving a small entrance like that of a beehive for the fly to get in; the fly having consumed as much as he requires, has, as the horticulturist says, high aspirations. Like the sparks, he flies upwards. To accommodate him in his ascensional movements, you must make an opening at the top of the cover, and apply to this opening a tube of glass with a ball at the end; in fact, an apparatus like a long-necked wine decanter turned upside down; the flies will climb up into the globe, and not being overburdened with common sense will never think of descending and getting out by the way they got in. There is one of these fly-traps at the Paris Exhibition in the park close to the *Ecole Militaire*.

DESTRUCTION OF ENGLISH BIRDS.—Just before the close of the session, the Rev. F. O. MORRIS, rector of Nunburnholme, petitioned Parliament, praying that a heavy tax be imposed on the possession of a gun, pistols being amply sufficient for all purposes of protection, and that the law of trespass be made more stringent with the like object in view, the protection, within due bounds, of each and all of our native birds. Mr. Morris sets out the following among other reasons: "That birds perform a most useful part in the economy of nature; that if they are unduly destroyed insects increase in similar proportion, and do vast damage to the produce of both farms and gardens; that birds are ornamental as well as useful, and give great pleasure and instruction to naturalists and others who observe their habits; that owing to the indiscriminate and untaxed use of guns they are wrecklessly destroyed in great numbers every year; that many important and useful species have in this way already become extinct in Great Britain, and that others have become more or less rare, and will in like manner be exterminated if some means

for their protection and preservation be not adopted. That in the year 1864 your petitioner published a suggestion that there should be a tax laid on guns for this object, and that such tax would bring in a very large revenue to the exchequer. That its enactment would at the same time do away with the vast amount of poaching; that it would be the means of saving many lives which at present are sacrificed every year by the incautious use of fire-arms in everyone's hands *ad libitum*, as well as otherwise."

EAST LONDON AMATEUR FLORICULTURAL SOCIETY.

The summer exhibition of this society was one of the best ever held in the eastern parts of London, and perfectly justified the sanguine expectations of its promoters, who secured for the purpose larger and better rooms than they have been accustomed to select for their exhibitions hitherto. On this occasion the show was held in the Grammar School, Tredegar Square, Bow Road, which though far better than the Vestry Hall, where previous meetings have been held, was yet insufficient for the accommodation of the company. The society has, in fact, outgrown the capabilities of the district, and it will be a matter of the first importance in the future management to find a place in which the whole of the contributions and the whole of the company can be assembled together without inconvenience. It is not at all surprising that this society should enjoy continually increasing prosperity, for the members of the committee work together in perfect harmony, and are untiring in their efforts to insure success. On the present occasion the contributions were numerous, various, and of excellent quality throughout. In the class for six fuchsias, Mr. Deacon took the lead, with Mr. G. Groves second, and Mr. Peters third. In the class for three fuchsias, Mr. Hawkes took first place; Mr. Deacon, second; Mr. Enness, third. Three fuchsias, cuttings of 1867, a good class, first, Mr. Hawkes; equal second, Messrs. G. Groves and W. Grove. Three miscellaneous plants, first, Mr. W. Grove, with a fine *Coleus Verschaffeltii*, *Ficus elastica*, and a *Caladium*; second, Mr. Deacon; third, Mr. Sinclair. In the class for best collection of plants, first, Mr. Deacon, with a splendid lot, comprising good examples of *caladiums* and *begonias*; second, Mr. Grove, who, amongst other good things, had examples of *Tritoma uvaria*, *yuccas*, *aloes*, *stripe-leaved maize*, and some beautiful *begonias*; third, Mr. Hardy; fourth, Mr. Howard; fifth, Mr. Sinclair; Mr. Grace, Mr. Archer, and Mr. Enness following. In the class for collection of geraniums, first, Mr. Deacon; second, Mr. W. Grove. Amongst other plants shown, special mention must be made of a fine *Coleus Blumei* and *Gloxinias* from Mr. Grove; and a collection of miscellaneous plants from Mr. Truschell, of Stoke Newington. Balsams from Mr. Sinclair were good.

Cut flowers were of course abundant. Mr. Hopkins, of Brentford, took the highest positions in all the large classes for dahlias with a brilliant display of flowers. In the minor class for dahlias, the leading exhibitors were Messrs. Homewood and W. Groves. Amongst miscellaneous subjects, there were charming bouquets from Mrs. Grove, Miss Grove, and Miss Larch; a beautiful fern-case from Mr. Ocraft, a stand of roses from Mr. W. Grove, and various fruits from Messrs. Grove, Smees, Enness, Schrier, and others. Mr. Wilkinson, nurseryman, of Old Ford Road, contributed a beautiful collection of plants, not for competition; and Mr. Allen, nurseryman, of Shacklewell, contributed in like manner plants, flowers, and decorations. On one of the days of the show 1,000 school children were admitted gratuitously, greatly to their delight, which was increased considerably by the distribution amongst them, by the Rev. Mr. Sutherland, of the prizes awarded by the judges for their contributions. They were afterwards addressed by the Rev. J. Carter.

At the dinner of the society, at which there were present more than the ordinary number of guests, Mr. Howard, the chairman of the committee, presented to Mr. Allen, of Shacklewell, a handsome piece of silver plate as a mark of the respect and esteem in which he is held by the members of the society, on account of the generous manner in which he has always assisted the exhibitions by his advice, his contributions, and his presence. We have frequently witnessed Mr. Allen's devotion to the interests of the society, especially in the contribution of plants and flowers in a prodigal manner, and we have great pleasure in recording this acknowledgment of his zeal and service. Mr. Allen returned thanks in an appropriate manner, and of course had the privilege of proposing the health of the chairman. May the cordial spirit which animates the members of the East London Society long continue!

BERMONDSEY FLORICULTURAL SOCIETY.

The annual show of this Society took place at the Holly Tree, Blue Anchor Road, Bermondsey. Though there were good contributions in all the classes, dahlias were the chief attraction. But not less important in respect of display were the designs in cut flowers, of which there were many, and some of them were highly meritorious. For example, Mr. J. Chesney, jun., exhibited a design representing the arms of the City of London made up of dahlia petals, an ingenious and beautiful piece of work. Mr. Lindus presented a floral reproduction of the Prince of Wales's feathers. In the class for 12 dahlias: first, Mr. Gueran; second, Mr. Rose; third, Mr. Beard; fourth, Mr. Burt. 6 dahlias: first, Mr. Gueran; second, Mr. Beard; third, Mr. Burt; fourth, Mr. Rose; fifth, Mr. Greening; sixth, Mr. Dench. 12 asters: first, Mr. Rose; second, Mr. Gueran; third, Mr. Beard; fourth, Mr. Mars; fifth, Mr. Burt. 6 asters: first, Mr. Rose; second, Mr. Gueran; third, Mr. Dench; fourth, Mr. Burt; fifth, Mr. Mars; sixth, Mr. Gage. The asters generally were good, and there was a capital lot of 12 from Mr. A. Russell, not for competition. 6 antirrhinums: first, Mr. Rose; second, Mr. Gage. 12 fuchsias: first, Mr. Greening; second, Mr. H. Thomas. 6 fuchsias: first, Mr. Greening; second, Mr. Clench. All the fuchsias were small, but, generally speaking, well-grown and good varieties. 12 asters in pots: first, Mr. Thomas; second, Mr. Dench. 6 asters in pots: Mr. Burt first. 6 balsams: first, Mr. Clench; second, Mr. Greening. The awards in the competition for devices were as follows: first, Mr. Gage; second, Mr. Chesney; third, Mr. T. Gage; fourth, Mr. C. Wells. The awards for bouquets were: first, Mr. Greening; second, Mr. Rose. There were some good collections of vegetables.

SUNSTROKE.—A correspondent, observing the frequency of death from sunstroke lately, suggests what might be an easily-obtained remedy, whether in the garden or in the field. Many a sportsman must have found relief on a hot day by putting in his hat turnip leaves or fern leaves. A thick cabbage leaf or two are very good, perhaps the best. Several pieces of white paper, with holes through them, would also be found useful.

KENSINGTON PALACE AND HYDE PARK GARDENS.

Kensington Gardens at any time of the year is always an interesting spot to the mere rambler, and to gardeners generally; for here is a fine collection of majestic and stately old trees, and a choice assortment of the newest shrubs, which collection, I think, is second to none in the kingdom. Mr. Mann, the superintendent, has taken especial interest in this department: they have been judiciously planted for effect; and correctly named for the convenience of the public. All these beautiful avenues and groves and glades are the work of Mr. Mann, who commenced operations somewhere about forty years ago. The old trees have been for years decaying, making great gaps that young trees cannot fill, and as there was space sufficient to admit a line of young trees in front of the old ones, this was done, and the result is that there are groves of half-grown and flourishing trees, the turf on which they stand smooth and level, and their stems distinctly seen, with room to extend their heads and branches. The old and tall trees in the rear look over the heads of the young ones, and blend their foliage with them in a very pleasing and striking manner, and as the autumn advances it will be more so, for the old trees change colour before the young ones, and must therefore enhance the ornamental effect of their association. It is said that in a grove or an avenue the same object is seen from beginning to end. Granted; but here is perpetual change and variety, for here is a grove of elms and an avenue of oaks—in fact, they meet and cross in all directions—and there are also groves of chestnuts, hornbeams, abeles, birches, and other trees: they have a simple and grand effect without any sameness or even formality, and in spring-time there is something so very charming in these rows of trees. Every line has its peculiar tint of green, which is soft, fresh, and delicate, producing inexhaustible sources of delight and admiration. But when we add 100,000 plants which blossom in these gardens and park in spring, the enjoyment of the walk is greatly heightened and varied. Such indeed is the case—100,000 plants are grouped in beds and borders, their diverse forms and colours contrasted and blended with admirable taste. This display adds greatly to the charms of returning spring. These 100,000 spring flowers pass away as the summer comes, and there are then planted 300,000 plants to bloom through the season. This number will I have no doubt startle some of our country cousins, who are apt to think that Londoners do not see anything but bricks and mortar, but they will see that flowers are not scarce—they are as numerous as the bricks. I fancy I hear some one say, "What a quantity! I almost doubt it;" but there is no mistake about it, as I got my information from Mr. Bullen, Mr. Mann's foreman and propagator, on Friday the 30th of August, as I had the good luck to meet with him on that day, and he had a walk round with me, and we went to every bed and border, and passed this 300,000 in review, and a pretty sight it was. We started from the Palace, and first took notice of the new geraniums. *Nimrod* was conspicuous amongst the lot, a good truss and a bright orange-scarlet flower; *Cardinal*, orange-scarlet, is a darker shade than *Nimrod*—Mr. Bullen thinks this the best geranium raised; *Rebecca* pleased me much. It is after the style of *Amy Hogg*, but I was assured that it was not so good as it looked. I inquired the reason: "It is too prolific of seeds," was the reply. *Crystal Palace Gem* is one of the good things here; and so is *Annie Williams*. The following sorts are very much cut up for propagation, which is a convincing proof that they are to take a leading part among the 300,000 next summer: A *Seedling* of their own, salmon colour—what I could see of this, I think it will be good; *Dr. Lindley*, *Lucius*, *Madame Barré*, *Rose Belle*, *Waltham Seedling*, *Donald Beaton*, *Duchess*, *Culford Rose*, and *Indian Yellow*. There were, of course, scores of others, but not so much thought of.

Mr. Chamland's cottage (Mr. Mann's head foreman, who took Mr. Massey's place) is as attractive as in former years: thousands of people are gazing at it this very day. It is planted thus:—

The beds in front of the Palace are, as usual, well done; the colours richly contrasted and harmonized, and the effect in every respect good. Here is a square piece of turf with beds.

No. 1.—Middle, *Centaurea ragusina* and a crimson *Calceolaria* mixed. All round this, a circle of *Verbena*, a seedling, a charming thing; the colour deep pink; the habit and style of growth like *Purple King*. The edging to this bed is *Lonicera aureo reticulata*. It was good indeed.

No. 2.—Centre, *Coleus Verschaffeltii*, planted in star shape; an edging of *Portulacas* and *Mesembryanthemums*; and the filling-up between the two *Cloth-of-Gold Geranium*.

No. 3.—Yellow *Calceolaria aurea floribunda*; a circle of the pink *Seedling Verbena*; and an edging of *Cerastium*.

No. 4.—Variegated *Geranium Annie* and blue *Lobelia* mixed; an edging of *Lonicera aureo reticulata*.

No. 5.—Centre, *Amy Hogg Geranium*; next, *Geranium Mrs. Whitty*; edging, *Purple King Verbena* and variegated *Alyssum*.

No. 6.—In centre, bright scarlet *Geraniums*, such as *Stella*, *Cybister*, *Waltham Seedling*, and *Donald Beaton*; next, *Geranium Bijou*; *Purple King Verbena* is the third row; edging, *Gnaphalium lanatum*.

No. 7 is like No. 6, except that there are light or pink *Geraniums* in centre, such as *Mrs. Whitty*, *Madame Rudersdorf*, &c.

Round on the east side of the Palace there are some good examples of bedding, such as variegated *Geranium* edged with *Iresine Herbstii*, blue *Lobelia*, and *Lady Plymouth Geranium*; *Alternantheras*, edged with *Sedum glaucum*. On the west side, a flower border is very attractive: the first row, or edging, is variegated mint; second, *Alternantheras*; third, yellow *Calceolaria*; fourth, *Geranium Stella*; fifth, *Ageratum*; and then a mixed lot blending in with the shrubs. It forms a highly picturesque scene.

On leaving the Palace, we made our way to the park, through the floral walk. This walk is 700 yards long, with a flower-border on each side, planted thus: First row, *Stachys lanata*; second, *Geranium Tom Thumb's Master*; third, yellow *Calceolaria*; fourth, white *Pyrethrums*, and then a mixture of all that is good.

We now come to Albert Gate, to the improvement, or new garden, that was made in spring, and it certainly is a fine specimen of modern gardening. It is a model of what a public garden should be. Here is a variety of different objects, grouped and arranged in a style which is new in composi-

COTTAGE WITH ROCKWORK AND IVY.

This border has in the centre *Crimson Nosegay*; on each side, mixed rows of pink and scarlet *Geraniums* and yellow and orange *Calceolarias*; an edging of *Lady Plymouth Geranium* and *Purple King Verbena*.

No. 1.—Silver Chain *Geranium*, mixed with *Viola cornuta*; a ring of *Mrs. Pollock*, and an edging of *Echeveria secunda*.

No. 2.—*Geranium Mrs. Whitty*; an edging of blue *Lobelias*.

No. 3.—*Amy Hogg*; an edging of *Cerastium tomentosum*.

No. 4.—Scarlet *Geranium*; edging, *Lobelia* and *Lady Plymouth Geranium* mixed.

No. 5.—Large flower-pots filled with mixtures, completely covering them.

tion and character. There is a distinctness and a certain marked feature of a positive kind, which the eye can dwell on with pleasure; and as you traverse it, the scene changes at every step. I think it will be agreed by all that the principal excellence of this artistic work is naturalness; such a term, too, is the only one I consider appropriate to describe it. The surface is not level, but irregularly undulating. The flowers, shrubs, trees, and specimen plants, with fine foliage, are grouped in the happiest manner, and with as much in-

tricity and variety as they can give to a lawn without destroying its character. In the hollows are ornamental foliage and sub-tropical looking plants, which are now so much admired for their noble and handsome leaves such as Caladiums, Cannas, Azaleas, Castor-oil plants, Dracenas, Ferdinandias, Ficus elastica, Yuccas, Maize, Palms, and Cordylines. The beds for flowering-plants are on level and open spots; nothing but the choicest kinds are brought together to plant here, and they are dispersed in beds of various sizes and forms; triangles, circles, ovals, crescents, scrolls, and other various forms, artfully disposed, sometimes in masses, leaving large open grassy glades, which are broken up by single specimen trees and shrubs. The masses are rendered light in character by one or two detached beds of a smaller size. In the arrangement of the flowers in the beds, the mixed system has been carried out. I like this plan for two reasons: in the first place, the plants need not be planted so close; and in the second, they have more room to grow.

No. 1.—A bed of Mrs. Pollock and blue Lobelia mixed. This is a bed that will satisfy the eye, and produce harmony of colour; the red flower is supported by the due proportion of the yellow leaf; the blue Lobelia is harmonized by the presence of the other two colours, and the green turf is a complement to the red.

No. 2.—Queen of Queens, a silver-margined geranium with brilliant scarlet flowers, and Lobelia; good.

No. 3.—Luna geranium and Mrs. Lennox geranium, two half circles of each, mixed with blue Lobelia. A fine Rhododendron in the centre, and four Ficus elasticus, thus—

No. 4.—Geranium Mrs. Pollock and Viola cornuta; geranium Luna and Viola cornuta; geranium Annie Williams and Viola cornuta; geranium variegated Stella and Viola cornuta; very good.

Here, too, are some fine clumps of Cannas; but the other side of Rotten Row is the place to see the Cannas; for there is a field of them, planted in beds, all shapes and all sizes. The sorts most in favour are Coccinea, Annei, Discolor, Gigantea, Limbata major, very fine; Warscewiczii, Zebrina,

Purpurea, Metallica, Indica rubra, &c. Each bed has an edging of a plant of another kind, such as Coleus, Centaurea, Iresine, Solanum, variegated Coltsfoot, Euonymus radicans variegata, and others. It is hardly necessary to say that the effect produced by such noble plants is grand in the extreme, and it does not require what is called a superior taste to appreciate their beauty.

After all, the things which I admired most were the bold and massive clumps on this new ground, and the way in which they had carried out the massing system: flowers and foliage are here tastefully combined. There is no doubt about the effect that may be produced in gardens by this method of embellishment. Also, these large clumps have edgings of Stachys lanata; then comes the mixture of the ordinary bedding plants, such as verbenas, petunias, calceolarias, geraniums, &c. Then come the dwarf ornamental foliage plants, such as Cineraria maritima, Perilla, variegated Maize, &c. Further back, Cannas, Aralias, Caladiums, Dracenas, and among these mixed standard fuchsias and scarlet geraniums. Then come the plants of noble aspect and leaves of elegant outline, such as the Ricinus or Castor-Oil, Nicotiana wigandoides, Pampas grass, Tritomas, Polymnia grandis, &c. The Polymnia requires plenty of water and a rich soil, and then it will have a free bold habit, and form a capital companion to the noble Ferdinandia emmens. Phloxes, dahlias, and hollyhocks also abound in these clumps.

Let us now have a look at Hyde Park. The flowers by Park Lane perhaps never were better than they have been this summer, and all that I have heard speak of the display there have pronounced it perfection. The keeping of this part is entrusted to Mr. Dennis, and well has he and his little staff done their duty—not a leaf out of its place, nor a dead one to be seen. From Stanhope Gate to Grosvenor Gate, a distance of about six hundred yards, is where the principal display is to be seen. The beds are here oblong, planted thus: On the right-hand side next the Lane there is a run of oblong beds on grass from one end to the other, principally geraniums, two sorts in a bed, about three rows in the middle of one sort, and a row between it and the edging, which is part of the way variegated mint and blue Lobelia. There are a few beds with yellow Calceolaria in the centre; this enlivens the whole. There seemed to be all the best geraniums used here, and all the shades from Stella down to Madame Vaucher, and they were nicely contrasted. Black Dwarf and Christine—Culford Rose and a silver-margined leaf—Calceolaria and Madame Barré—Boule de Feu and Duchess—and others too numerous to mention.

On the left-hand side next the Park there are likewise oblong beds, nine in all, similar to those on the right, except the edging and the next row. The edging is Gnaphalium lanatum; next row Purple King Verbena. The middle bed is the key-bed—three rows of scarlet and one row of silver-edge geranium. The next two from the centre, Mrs. William Paul and Cloth-of-Gold. Next pair, Stella and Annie geraniums. Next pair, Madame Vaucher and Christine. The ends, Cybister and Golden Fleccc. Between each two beds is an evergreen oak.

Now we come to the ribbon border, about four hundred yards of it edged with Cerastium tomentosum; next Purple King Verbena; next a silver-loved geranium; next yellow calceolaria; next scarlet geranium; top line Perilla. Beyond that mixed shrubs. This looks very well, but the calceolaria ought to have been where the geranium is, and vice versa, as the calceolaria is too tall for the geranium, and it would have been better for contrast of colour. At the back of this ribbon border in the other walk is a fine example of panel painting. This, I think, is an extravagant way of planting, for it takes such an enormous quantity of plants to carry it out properly, as it is done here. There are three examples: in the first the groundwork is silver variegated geranium; within this blocks of Coleus Verschaffeltii (1); Crystal Palace Scarlet geranium and round blocks of Amaranthus melancholicus (2) :—

The next panel has a groundwork at each end of Heliotrope, round clumps of Calceolaria Prince of Orange; the centre ground of this panel is Tropaeolum with round blocks of Mrs. Pollock, and edging of Iresine Herbertii.

The next panel has groundwork of Verbena Lord Raglan and round blocks of yellow Calceolaria; the centre is Cloth-of-Gold Geranium; the edging Lady Plymouth Geranium and blue Lobelia mixed. The next groundwork is scarlet Geranium Boule de Feu, six round clumps of Cineraria maritima, the edging Verbena Purple King and variegated Alyssum. This brings us to Grosvenor Gate; from thence to the Marble Arch the beds are more thinly scattered, on account of the large trees there. But still they are very neat but elegant, and to name them would be only a repetition of some of the beds that are to be seen in other parts of the Park, and likewise near the palace in Kensington Gardens, which I have described. N. COLE.

STORING FRUIT.

We so seldom see a proper provision made for the storing of fruit, that I am induced to offer some remarks upon the subject that may be useful to those who really wish to enjoy well-kept apples and pears, for it is one thing to grow fruit and another to keep it.

In the first place, where any quantity of apples and pears are grown, both for the dessert table and for culinary purposes, a properly constructed fruit-room should be provided. In gardens of any pretensions we usually find a fruit-room, but in many there is none at all. But, to see a well-constructed fruit-room combining all the essential conditions necessary for keeping fruit is an exception; the position is either unsuited to the purpose, or some rickety tumble-down place, for which a stranger would be at a loss to find a name, is chosen for the purpose. A knowledge of this, gathered from my peregrinations into different parts of the country, has induced me to direct the attention of fruit-growers to the subject, and at the same time to point out some of the defects of fruit-rooms.

The position of a fruit-room should undoubtedly be so that the internal atmosphere should not be materially influenced by the outward elements, either by heat or cold; and to insure this, it must be somewhat sheltered, but not enclosed either by large trees or other buildings. It may stand in a range with other buildings, providing the precaution is taken that those adjoining do not shade or shelter it too much. A span-roofed structure, with its two sides facing east and west, is unquestionably the best position and form. The spot should be dry by being well drained if necessary. The most unsuitable form of fruit-house generally seen is one placed as a lean-to against a high wall with a northern aspect. Not unfrequently, we see what is termed the fruit-room in a musty old loft, and perhaps beneath it a great furnace fire going night and day, sending its waste heat and sulphurous smells up between the crevices into the fruit-room, while perhaps just through the wall is a forcing house maintained at a high temperature, hence the wall which divides the two becomes heated, and the air of the fruit-room is consequently heated by conduction from the wall. Where this is not the case, I have seen many examples where the room has been injuriously close and damp for the want of ventilation.

Those who have had any experience in this matter will agree with me in saying, that to have fruits in perfect ripeness, according to their different seasons of use, the most vital point is to keep the air of the room as near as possible to one even temperature; for as heat favours the maturation of fruit, so does cold retard it, and both are alike injurious to the promotion of good-flavoured fruit. This fact being acknowledged, we have to consider the kind of material best suited to the building of fruit-rooms; and to every experienced reader wood will present itself as eminently suitable as being the best of non-conductors of heat. My idea of the building of a fruit-room would be to have brick foundations to just a few inches above the ground, with the ends and sides of wood, composed of good stout uprights. These, both inside and outside, I would have neatly boarded, and the space between the boards, say about four or six inches, filled up with sawdust. Such a structure would not only prove a good non-conductor of heat, but would be capable of resisting a great amount of cold, thus securing one of the most essential features in a fruit-room. The internal fittings of such a room should consist in a tier of wide shelves all round from top to bottom, and in the middle of the building another tier of shelves, round which there should be ample room to move about. Means should be provided for admitting a current of air, both at top and bottom, at about two different places along each side, and the same at the apex. Systematic ventilation is very desirable to carry off the exhalations from ripening fruit, and, in my opinion, unless we maintain a sweet pure atmosphere the flavour of fruit is materially injured; in fact, I believe a certain amount of fresh air is necessary in promoting the ripening process of some of our best pears, and as to the late keeping sorts, I am not sure if we should not improve the flavour of them if we were to transfer them to a shelf in the forcing house a few days before they come into use, for what is favourable to those kinds which ripen in the open air cannot be an injury to others.

Very many of our most luscious pears are not valued in every case as they deserve, simply because people do not know their right season of use, and for the want of a proper place to keep them in. Yet many take the greatest care and spare no end of expense in cultivating, and then indignantly rebel the suggestion of the gardener when he sets forth the necessity of a proper room to keep them in. This is not as it should be, and until more suitable structures are built for the keeping of fruit, so long will the wealthy deny themselves one of the pleasures of their gardens. The coal-hole and other cellar-like places, in which I have seen some beautiful collections of fruit, would, I am sure, be more than sufficient to disgust those who had to eat them, if they only took the trouble once to see the condition in which they were preserved for their table.

With a fruit-room constructed as above advised, the gardener may do much towards improving the flavour of his fruit as well as prolonging its season of use; but no good will arise by creating any unnatural condition, for, as above stated, cold encourages the preservation of fruit by retarding its natural season of ripening, but fruit so treated is of little value in point of flavour, and the same holds good when any extra degree of warmth is maintained to induce it to ripen before its time. Light and warmth I believe to be essential at the point of ripening, but when applied before that time it will prove an injury.

Next to a suitable structure comes the proper management of a fruit-room, and doubtless this has much to do with the keeping qualities of the store. Cleanliness unquestionably ought to be most rigorously followed-up, as if decaying fruits are allowed to remain with the others they soon contaminate all they come in contact with, thereby increasing the number of decaying fruits. Next to cleanliness, a judicious system of ventilation should be adopted, unless the weather is damp or frosty; this is important to keep the air of fruit-rooms sweet and pure, otherwise the fruit will be hastened on to decay. As to the sweating and wiping process, which some writers tell us

is essential, it had better be left undone. The sweating to a certain extent cannot be prevented; but lay them out thinly on shelves, and it will be much less than when laid in large heaps, and the sticky substance which this sweating leaves upon the fruit rather adds to its keeping than otherwise.

Those who grow any quantity of fruit, and take an interest in it, will be careful to have a note-book at hand on a shelf, and to keep a careful record of the particular merits of any good subjects; as, for instance, the time of gathering each sort, the time of coming into use, and the number of days or weeks they kept in good condition. Such brief notes as these I have found valuable records for a reference.

Many late apples and pears are gathered before they are ready: the best and safest guide I have found is not to gather them before the fruit leaves the tree moderately easy.

I will remark, in conclusion, that of the two worst fruit-rooms I have ever seen, one was entirely underground, and the other was heated by a flow and return 3-inch hot-water pipe, over which there was no control, as it was connected with a boiler kept at work nearly all the winter. Such a method of disposing of fruit should be designated the slow-cooking and decomposing process; it cannot be said to be preservative. J. C. CLARKE.

MESSRS. E. G. HENDERSON AND SON'S NURSERY, WELLINGTON ROAD.

Temp'ted by the description of a new foliage bedder to be seen in this nursery, I made my way there direct. The report went so far as to say it eclipsed all the Sunsets, Meteors, Golden Belts, and Tricolors, and was everywhere the grandest leaf-plant out. In fact, it put all variegated fuchsias and geraniums in the shade. So I went to see it, and to judge of it on its own merits; and from the top of an omnibus which passed this establishment I caught the first sight of this foliage bedder, and was thereupon convinced that not one word too much had been said in its praise. Now I will tell you what it is, and then I will try to describe it. It is neither more nor less than a fuchsia, raised from seed by Mr. Bard at this establishment. They have named it *Golden Fleece*. A plant was sent to the Floral Committee, and they pronounced it a sport from the *Cloth-of-Gold*; but what should have guided them to come to that decision is a mystery to me, as Messrs. E. G. Henderson wrote to say it was a seedling, but the committee could make nothing but a sport of it. The style of growth is dwarf and branching; a medium size leaf, very glossy, and shining like gold; the flower-bud (including tube and sepals) is light crimson; the corolla blue. What a beautiful contrast we have may be imagined—a golden ground spangled with light crimson, and a dash of blue. The plant has a very healthy-looking appearance, and the more it is exposed to light, air, and sunshine, the brighter is the colouring of the leaves. Foliage bedders have acquired immense importance; indeed, leaves are fast superseding flowers in the parterre, and they certainly have the advantage of producing decided effects from the moment the plants are in their places. But still there is left a lingering desire to see the flowers; and many a time, when I have been admiring a bed of fine foliage plants, the question has been asked me, "What sort of a flower does it bear?" My answer has been, "Oh, it is grown principally for the leaves; the flower is not much." They have said, "Yes; but I like flowers, let the leaf be ever so beautiful." Well, in this *Golden Fleece* fuchsia we have them both combined and harmonized, and, in my estimation, it is the best bedder of the season, and I shall strongly recommend it for decorative purposes, either in the flower garden or in the greenhouse.

All the new bedders and the best of the old ones are to be seen here, and I noted down a few that pleased me most. Of Verbenas, there is a fine healthy-looking stock one, called *Polly Perkins*, a hybrid from *Velvet Cushion*, with *Purple King* habit and magenta-coloured flowers; very free, and literally covered with bloom. There is a row of this verberna 40 feet long, planted by the side of the fuchsia *Golden Fleece*, with an edging of that excellent lobelia, *Indigo Blue*. The effect is charming. The lobelia is deep blue, with large white eye; but this is not the very best lobelia, I think; for one called *Speciosa spectabilis* is the richest blue of any I have seen. A scarlet verberna, in a seed-bed marked X Z, was a brilliant object, close and compact; the flowers almost rested on the foliage, and were so numerous that scarcely a leaf could be seen. I think this will prove a gem of the first order for an edging plant, for it is just what we want: our plants for edging are principally blue and gray; a fine scarlet ring next to the green grass would be glorious, and I believe this verberna will be just the thing to do it. Of Geraniums, the collection, as regards variety, is the most extensive I am acquainted with. Amongst the kinds that took my fancy, and which I think the most deserving of notice, are *Countess of Tyrconnel* and *Edwinia Fitzpatrick*. They are both decidedly improvements on Mrs. Pollock, and freer in growth, more of a branching habit and larger foliage, with richer markings. Of golden bedders, one named *Princess of Wales*, with leaves of a rich lemon-yellow ground tint, bright bronze-red vandyked zone, very dwarf and compact, the leaves very much lobed. *Canary Bird* is another of this class, but not so dwarf, and the leaves are round: I have no doubt that they will both become great favourites. *Viola cornuta Mauve Queen* (Mr. Wills's variety), and *Purple Queen* (Mr. Bennett's variety, of Osberton Hall), are planted in lines side by side. Bennett's variety is decidedly the best, being a close compact grower, and a freer bloomer, consequently the most suitable for edging. Mr. Wills's is best planted alternately with the miniature variegated geraniums. The effect is charming, both with the golden and silver-leaved varieties. The foot-stalk of the *Mauve Queen* is tall and slender, and the flowers mix in with the flowers of the geraniums; or you can pick off the geranium blooms, and the effect is still beautiful. *Golden Feather Pyrethrum* is planted here all sorts of ways to show its effect. It is certainly a good and useful thing; its uniform neatness and compact and dense growth forming an equal surface, it makes it just the thing for a front line or outer circle. It will contrast with any colour except white, and form an elegant feature. The *Alternantheras* have a pleasing effect when employed as a margin to a circular bed on grass; they will contrast well with blue lobelia, which may be planted behind. Mr. Joseph Newton told me that this plant is very beautiful in the gardens of Italy, where it is extensively used. It is a Brazilian amaranth, and of course is rather tender, but it will make a useful summer bedder. There are three sorts—*A. paronychioides*, the coloured leaf is a mixture of orange and carmine; *A. spathulata*, carmine and purple; and *A. versicolor*, carmine and claret lines.

The most dwarf and closest-growing silvery-leaved plant is *Antennaria tomentosa*; it is even with the surface. It is a first-rate thing to use as an edging for a bed of *Sempervivums*. That is how it is used here, and

it sets the *Sempervivum* off to the best advantage. The *Sempervivum* are becoming great favourites; and Messrs. E. G. Henderson have one called *S. Californicum*, with chocolate points, which I believe will please everybody. It is six inches over the crown; close, neat, and compact. One more plant, and my notes are ended. It is the last, but worthy of a place in the first rank as an edging plant. It is the lavender cotton, *Santolina incana*. It has a good effect at a distance, and when under the eye it is pleasing to look upon; the little leaves are like a pavement of crystals. There are many more things worthy of notice, as we are all aware; but, as I had only half-an-hour to spare, I jotted down just a few things that particularly took my attention; and if my fellow gardeners feel as much interest in reading them as I do in writing them, we shall be both well paid for our trouble. N. COLE.

AN OLD MAN'S TROUBLES.

After a gay season, some one has said, follows a dull one, and I am inclined to believe in the prophet who said so, for since he shook you so heartily by the hand, Mr. Editor, in that provincial town that was gay with all the brilliant attractions of a flower show, and miles of bunting and evergreens, the old man has been somewhat dull. Of course you know how much the old man enjoyed himself the short time we were together, and no doubt you will think (if you don't say so) that an old fogey like me ought not to let trifles trouble him. But I'll tell you what it is, that beautiful flowers, pretty ladies, and charming music, are as attractive to me now as ever they were; and you know that I was delighted beyond measure,—in fact, for the time I blest my stars that I belonged to the noble brotherhood of gardeners, but since that happy day I have been obliged to sing to a different tune, and this rather troubles me; and now you will be asking, What troubles you? and I will tell you. You have known the old stick long enough to know that I never allow pleasure to interfere with business for more than one day—or at the most, two at a time. So the next evening after the one I had spent in your company, having an eye to business, I took a gentle stroll through the flower-garden, principally to ascertain if anything had been forgotten or overlooked in the hurry of propagation for next year's display. As the family were at dinner, and the men had left work, I had the place to myself, and, naturally enough, the condition of the flower-garden, after a week's delightful summer weather, gave me much pleasure to look upon. And here I must tell you I am rather given to serious moods at times, when alone, and nothing vexes me more than to be disturbed in the midst of them. Even in my young days I could scarcely forgive the tiny voice and prattling feet of the little ones if they disturbed me when contemplating the beauties of a distant scene, or arranging the more important work of the garden for the following day. It was in just such a mood I carelessly threw myself into one of the rustic seats which command a view of every flower-bed in the garden. Finding that nothing had been overlooked, I felt at ease, and very soon I found myself comparing the serious business of flower-garden decoration in the present day with what it was when I was a stripling. I forget at the moment of writing if I sighed for the fate of many old favourites of the flower-garden now almost extinct, but if I did I am not ashamed to own it; for although we were less brilliant in colours at that time, we did not sacrifice nine months of the year, with double and treble the amount of labour, for a three months' display of flowers. No; we had a just appreciation for the chaste, the beautiful, and the good, to sacrifice our time and means upon a few species of plants to the exclusion of all others. To have done so in my early days would have been considered a great serious mistake. But times and tastes are changed now, and the old man feels it, because he has neither time nor means to cultivate a few of those old friends that would solace and please him. It may be well for the younger members of our craft that they have not old friends to lose, and therefore I forgive them for the share they take in promoting the advancement of the present system of bedding. But while exonerating them thus far, they must permit an old man to tell them they are in their enthusiasm ignoring the utility, the beauty, and the many claims that our hardy border plants should have upon their attention.

The very name of hardy border-plants puts me in better spirits, and if I speak the truth, my attachment to the GARDENER'S MAGAZINE has been principally brought about because its pages have so ably and so timely advocated their claims to notice. I would that other serials had the same inclination, and as much ability, to carry it into effect. But thanks, many thanks to our worthy Editor, and "The O'Shane," a reference to the last two volumes will put every one in possession of all the information it is possible to desire or to give of the best hardy plants known to English gardens. I presume the other gardening papers know this, and so they keep pretty silent. I admire their modesty, for it is better to remain silent than to publish stale records.

None but those who have been occupied with these old subjects, and that still retain an affection for them, can understand how much an old man like me delights to refer back to the date when especial care was taken to have a few beds of choice pinks, to say nothing of picotees and carnations; and when all the hardy annuals were carefully sown in autumn and preserved through the winter, adding cheerfulness and beauty to the late spring months. And well do I remember what inward pride and satisfaction I felt when the head gardener placed under my charge a choice collection of auriculas, and how proud I was to show them to friends, and extol their beauty. With the recollection of all this, seeing, as I do, in my mind's eye, the chaste and beautiful markings of many of these, my old favourites, I long for their more extended cultivation in the present day, feeling confident that, in the present state of refined taste, if they were more largely cultivated, they would soon outshine our present short-lived and gaudy system of flower-garden decoration. But, good reader, you must not be ill friends with the old man for what I have said above. The present bedding system has much to recommend it I do not deny, but its pleasures are so short-lived that I think you will agree with me in saying it ought not to monopolize and cause the extinction of many useful subjects which, if cultivated properly, would give us a much longer display of flowers, if both were grown on a moderate scale.

I think now, Mr. Editor, I have told you all my troubles, and you, I think, will share at least a portion of them with me. This knowledge is some consolation to me, because your generous nature will, I know, prompt you to look over the follies and whims of

THE MAN WITH THE BLUE APRON.

STRAWBERRY HILL.—A contemporary informs us that an Italian poet has written a poem of 900 lines about "strawberries." If this be the case, it is decidedly a most audacious attempt to play old gooseberry with the muse.—*The Tomahawk.*

ORNAMENTAL LEAVES FOR FLOWER-GARDEN.

(Continued from page 406).

Continuing the subject of variegated or ornamental-leaved plants for decorating the flower garden, I would wish to remind my readers that I am not unconscious of the fact that many of the plants that have and will be noticed are not by any means of recent introduction. Novelty is not my object, but rather to search out and give prominence to those jewels of floriculture which shed a lustre around the garden, when tastefully employed, by the splendour of their leaves alone.

ALYSSUM VARIEGATA (or *Koniga var.*).—This unique silvery-leaved plant, from what I have observed, does not appear to be so generally cultivated as it was a few years ago. Of all the dwarf compact habited plants that, as edgings, are used as a contrast to harmonize with the colour of the flowers of other plants, this *Alyssum* may be ranked among the most deserving of our notice. If intermixed or planted alternately in a bed with Purple King verbenas, or used parallel in rows with the latter plant in a ribbon border, the result of either arrangement would be charming, especially during bright weather. As a bedding plant for small beds, it is strikingly adapted, chiefly for the myriads of snowy white flowers it yields in constant succession during the autumn months; but, employ it which way you will, it is excellent. The best season for propagating it is the spring, as cuttings root then with greater certainty than in the autumn. That I may obtain a good supply, my plan is to select at least six plants from those struck in the spring. These are kept growing as single specimens in pots during the summer months. By frequent stopping of all the strongest shoots and occasional shifts good bushy plants are obtained, for withstanding the various changes to which plants growing indoors are subject to throughout the winter months. The greatest danger in the winter season they have to contend against is an excess of moisture either to the foliage or roots.

BALM GOLD VARIEGATED (or *Melissa vulgaris*).—This once popular favourite plant for edgings is now overlooked by many who formerly admired it, yet its worth is not to be despised for that. Though perfectly hardy, and perhaps a little too weedy in its growth, still, by attention in trimming and stopping the shoots, it can be so cultivated as to attain only a few inches in height. Thus trained it has a very neat and effective appearance, especially when used as an edging to a ribbon border of some extent. Although its roots spread widely, affording plenty of offsets, yet if you are anxious to preserve its true variegated character and dwarfness, then increase it annually in the autumn by cuttings. For the economizing of space in storing them away in cold pits or frames during the winter months, use square boxes of a few inches in depth, into which put some sandy soil, inserting your cuttings as thick as you consider advisable; from thence they are to be planted out in the spring into their summer quarters. I have seen front lines of this balm left in the same spot for several years make a splendid display of golden leaves in April, May, and June, but towards the end of June it becomes coarse and unsightly. Our Editor, I believe, first introduced this plant to public notice, having turned it to excellent account in the experimental garden at Stoke Newington. There is a border there at the present time which has been planted ten years, and in the early part of the summer it surpasses Golden Chain geranium, but towards autumn it loses its beauty completely, and has the character of a weed.

VARIEGATED MINT (*Mentha var.*).—Everywhere known as a splendid silvery edging plant. There is but one rule to observe, and that is to propagate it annually. If left in the ground it becomes coarse.

COLEUS AND ITS VARIETIES.—These plants have within the last few years gained an ascendancy among bedders that are used for their remarkable foliage. They are entitled to the encouragement given to them, when striking effect combined with richness of colour is considered. Hitherto *C. Verschaffeltii* has occupied the foremost place, but of late there are other varieties of the same species that bid fair to outrival the old favourite, viz., *C. marmorata*, *C. Gibsonii*, and *C. Veitchii*. The latter variety is considered to excel all of them in point of attraction both in habit and growth, the leaves being large and of a dark purple colour; however, as a bedder its properties have yet to be tested. *C. Gibsonii* in growth is bushy and much dwarfer than *C. Verschaffeltii*. Its merits as a bedder have been sufficiently proved to recommend it for flower decoration; the colour of the leaf being a light green blotched with crimson purple, it makes an excellent pot plant for ornamenting the conservatory, especially when grouped with lilioms, fuchsias, &c., during the autumn months. I would not advise those whose bedding system is limited to use the *Coleus*, as should the summer prove unfavourable in regard to a deficiency of nice genial growing weather, it would be a disappointment; for to maintain it in a healthy state and fully develop its true character both of foliage and colour, it requires a warm and rather dry season. The great difficulty you have to contend with in preserving the plant during the winter months is damp; water should not be allowed to touch its leaves, and just enough supplied to its roots to keep it alive. The best place is a warm corner of the stove. It strikes freely from cuttings in the spring, from which good plants may be obtained for bedding or other purposes throughout the year; so that if you are cramped for want of space, a few strong plants kept through the winter will be sufficient for the work of propagation. The present season, being colder than the average, has been a bad one for every variety of *Coleus*.

CENTAUREA RAGUSINA CANDIDISSIMA.—For large beds this beautiful silvery-leaved plant is exceedingly well adapted, and more so when used for bringing out the fine rich colours of such dark crimson foliage plants as *Coleus Verschaffeltii* and other plants of a similar character. But with the latter variety it is well contrasted for effect, especially as an outer edging to the bed, but such beds should form the inner circle of the flower garden, on account of their robust growth, unless they may be placed in isolated situations. This *Centaurea* is propagated from cuttings either in the autumn or spring. But the plan generally adopted by those who hed out on a large scale is to keep a few stock plants throughout the summer in pots; these will afford the best cuttings either the same autumn or the following spring, especially if you have kept them pruned in the earlier stages of their growth. Such practice will produce an abundance of young shoots; these strike root much quicker and with greater certainty than do the coarser shoots obtained from the summer growth in the beds.

CENTAUREA RAGUSINA COMPACTA.—I am not practically acquainted with the habit or character of this plant, but it has been advertised this season as being an improvement on the former variety, both in neatness and elegance, being of a much dwarfer and more compact habit, and possessing a bright silvery leaf. I should advise every practitioner of bedding to make acquaintance with it.

ALTERNANTHERAS AND THEIR VARIETIES.—This pretty but neat group of plants belonging to the *Amaranthus* family claim special attention. The dark but rich coloured foliage of these plants has at present made but little inroad

into our flower-garden decorations, being but of recent introduction. But I have no doubt that another season will find them hailed as a great acquisition to the list of what may be termed miniature foliage plants for margins and other kinds of borderings or edgings. A short time since, I had an opportunity of pencilling a few notes, on the properties of some of the varieties that I saw at Mr. H. Cannell's Nursery. Since that period I have visited Battersea Park, and there seen them used with rare taste and judgment. *A. spathulata* formed a margin to *Lobelia pumila elegans*, a most lovely blue flower. The blending of the foliage of the one with the flower of the other was really good, and particularly so as they were so nearly matched as regards height and habit, though the *Lobelia* had the advantage in breadth. In our walks we found the same variety of *Alternanthera* forming an edging to a bed of Golden Fleece geranium: in both instances it was very telling when the sun shed its rays on it, as then its various shadings of colour, consisting of pink, crimson, brown, and red, were beautifully blended. Being a native of Brazil, no doubt the *Alternantheras* will exhibit their beauty best in warm and dry seasons. I infer this from the effects wrought on them as the season draws to a close: its beauty of late in regard to colour has been on the decline, while the *Coleus* and *Iresine* still preserve their colour; yet withal it makes a decided change in our bedding arrangements while the season lasts. Of the varieties in cultivation, *A. paronychioides* and *A. spathulata* are certainly among the best. The former variety, no doubt, will have the preference among cultivators. There is a closely allied plant named *Teleianthera versicolor*, which possesses broader leaves than any of the *Alternantheras*. My advice to those who are anxious for novelty in their flower garden is to purchase some plants, and propagate sufficient for requirements next year. Early in the spring, the treatment recommended for the *Coleus* will apply to the *Alternantheras*, they being so closely allied in their constitution.

ARABIS LUCIDA VARIEGATA (or *Golden Arabis*).—This is one of those valuable miniature plants, in respect to height, that are indispensable for front line of ribbon border, and for edgings to beds. I think it would be much more sought after if its glowing effects could be seen as cultivated in the nursery ground of Mr. B. S. Williams, of Holloway, who is the original distributor of this welcome addition to the list of hardy variegated plants, the latter qualification causing it to be all the more acceptable. It preserves its uniformity of character throughout the season without the necessity of having to resort to the knife so frequently as in the case of many other foliage plants, for the purpose of keeping them in good trim. That its golden foliage may be seen the better, pick off all flowers as they appear. The plant is readily propagated by division, either in the autumn or spring. It attains its greatest perfection on sandy soil, and for several years past has been one of the best edging plants used at Kew.

LONICERA AUREO RETICULATA (or *Japan Honeysuckle*).—This is a remarkably handsome variegated plant of the golden-leaved kind. The stripes or markings of the leaf are very distinct. Although a climber, it makes a first-class plant for a dwarf edging; this is done by shortening the shoots as they grow, and otherwise pegging and training when growing. As a climber, the long shoots are admirably adapted for coiling round the stem of *March's Epergues*, when used for the centre of a dinner table. It also has a very pretty effect trailing over the sides of window flower-boxes, if planted in them. It is perfectly hardy, but I consider it advisable to propagate every year, and grow them under glass during the winter months if intended for bedding. Mr. Hibberd has proved its perfect hardiness, for he planted it on a rockery in the first year of its introduction to this country, and it has grown most luxuriantly.

CERASTIUM BIEBERSTIENII.—This variety quite supersedes the well-known *C. tomentosum*; being more robust and of freer growth, the shoots retain their erect position much better. It is perfectly hardy and increases readily either from cuttings or divisions of the roots. It is but fair, however, to our old friend, to say of it that the bluish tinge of *C. tomentosum* is greatly in its favour where a silvery lustre is required. JNO. F. McELROY.

CAMELLIA CULTURE.—No. IV.*

Those who are so favourably situated as not to be obliged to place their plants out in the open air during summer, will have nothing more than the ordinary routine of watering and air-giving to think of in connexion with them at this season of the year. But with those who have not the desired convenience to give them summer quarters under glass, the case is very different, as, being under the necessity of placing them in some sheltered place out of doors, the time is now come when they must be thinking of their removal to more secure and favourable quarters. As this part of the management of plants so treated requires some care, it will, I think, be advisable to state briefly the points that should be attended to in the work of housing them.

In the first place, unless the pots have stood very evenly upon some smooth hard surface, it is more than probable that some worms have collected in them, and in every case where there is a doubt about it, means should be adopted to free the soil in the pots of these intruders. The simplest and therefore the best means of doing this is to dissolve a peck of fresh lime in about twelve gallons of water. Let this stand until the water gets clear, when it may be used with perfect safety; each plant should be thoroughly moistened with this clear lime-water, which will soon bring the worms to the surface, when, as they come up, they must be removed.

The next point of importance in connexion with housing these plants for the winter is to see that they are not taken into the house with their roots suffering for the want of water. It sometimes happens in dry autumns, when the plants have been standing in sheltered situations, that they get very dry at the roots. In this case ordinary waterings are not sufficient to thoroughly moisten the whole ball of earth, and this is especially the case with large plants standing in tubs

*The former papers of this series were published as follows:—No. 1, Feb. 16; No. 2, March 16; No. 3, April 27, of the present year.

and large pots. Many persons seem to forget that when such plants are thickly studded with branches and luxuriant leaves that extend far over the dimensions of the pots or tubs, that an ordinary shower of rain does not find its way to the roots of the plants, on account of the leaves and branches which extend beyond the pot, and carry it over the point to which the tub or pot extends.

I have too many times seen plants suffering for the want of water under similar circumstances, when those whose duty it was to see that they were properly attended to thought that sufficient rain had fallen to well water them, that I know I cannot too strongly urge upon the cultivator the importance of giving proper attention to this matter when taking his plants into the house for the winter. As to the time of attending to it, it does not matter whether it is done immediately before or after they are taken indoors, but they ought not to be allowed to go unattended to many days after they are put in their winter quarters. With very large plants in tubs or large pots, more care is necessary, as the watering will have to be repeated for two or three successive days, if they are very dry. But with smaller plants the work may be done at once, by placing the pot in a tub of water, and allowing it to remain there two or three minutes.

The next important matter is to see that they are not subjected to any great change, or it may be the means of causing them to cast their buds. It would be bad management, directly they are taken into the house, to keep them shut up close and warm; there should be a current of air kept up through the house night and day for at least a week. The next week the house should be open all the time there is daylight, as any coddling at this stage will be liable to prove an injury to the plants.

Every Camellia, whether in the north or south of England, should be housed by the end of September, as the drenching rains we sometimes have about that time are very hurtful to them, if accompanied with a low temperature; and when we get October here, we are never secure from a few degrees of frost. The after management will be to give water liberally to those most forward in blooming, to assist them in swelling their buds; those which do not show an inclination to flower until the spring must have water more sparingly. Keep the syringe or garden engine plied freely amongst those that are not in flower at least twice a week, as a fine glossy foliage is not only more healthy, but more sightly than leaves covered with smut and dirt.

J. C. CLARKE.

THE EXTENDED VINES AT RAHENY.

During the current and previous year not a little of the space of the horticultural press has been occupied with the discussion of what is called the "restrictive" and "extension" systems of vine-growing. By the first is meant allowing only one or two rods to each vine, and cutting or spurring back closely; by the second, having only one vine in a house, and allowing it to extend till it has filled it with bearing rods. By some writers the latter has been spoken of as something new, which is by no means the case. The Hampton Court vine in England, and the large vine at Castleton, Co. Kildare, in this country, are examples of it; others will, doubtless, be familiar to our readers. It is now some years since we brought prominently before the public a more modern, but, perhaps, about the finest, example of it to be met with anywhere, in a notice of the large *Hamburgh Vine* at the Viceregal Gardens, which, in a very brief period, has been made to fill a house nearly eighty feet long and proportionately wide with splendid wood and magnificent crops. We propose to-day to direct attention to another long-existing example of it in the neighbourhood of Dublin, which, at the same time, may serve to illustrate what may be called the anomalies of grape-growing, more especially as regards the vine border.

At the Cottage, Raheny, formerly the residence of the late John D'Arcy, Esq., and now the property of one whose name is not unfamiliar in the agricultural and horticultural worlds—Mr. Marino—there is a range of pine-pits, nearly ninety feet long by about sixteen wide, with a south aspect. The ends and back wall are of brick, with low, upright, glazed sashes in front; the whole of sufficient elevation to admit of head room, and a passage round the tan pits in the centre. The whole is divided into five compartments—we suppose for the purpose of succession plants, &c. The border immediately in front was, until this year, occupied by a corresponding length of substantially-built melon pits.

During Mr. D'Arcy's time pines were always grown, and, we believe, successfully. It appears, however, that he or his gardener—and it must be a good many years ago, too, if we are to judge by the appearance of the vines just now—thought a good bunch of Muscats from the roof might be had as well as a good "Queen" or "Cayenne" from the pits. But, then, where were the vines to be planted? Where was the border for them? The place of the latter, in fact, was occupied by the melon pits; at the ends were walks; forty-five feet of the bank was occupied by a shed, where the garden assistants lodged, leaving only six feet of a narrow roadway between it and a high garden wall, so that the rays of the sun rarely, if ever, fell on it. Well, in this most unpromising spot, and in the two angles formed by the above-mentioned shed with the back wall of the range of pits, a Muscat vine was planted, and, as far as we could see, without any preparation whatever, in the hard, impervious gravel of the roadway. Up the back wall, snake-like, the thick rugged stems of the vines ascend, and insinuate their heads immediately where the sashes of the roof rest on the back wall-plate. If there was little preparation for the roots outside, there was less method in the training inside. At present the stems of these vines, where they enter under the roof, are about a foot in girth. From this point rods were conducted down towards the front, then somewhat parallel to it up again, and,

in fact, any way and every way. Other rods were conducted into the adjoining compartment, and allowed to cover the roof in the same way, and so on, till the entire eighty or more feet of roof was filled with bearing wood. Rarely indeed, if ever, have we seen heavier crops of Muscats than these two vines produce. And, further, we remember some years ago seeing bunches cut from them characterized by the very highest finish of which the variety is capable, and which adds so much to its appearance on the table.

These vines are in the highest health, and the crop of the present year abundant as any that went before it. Save the indurated road surface at the back of the house, the only apparent feeding ground for the roots is apparently little else than what looks like accumulated sweepings in the angles formed by the junction of the ends of the shed and the back wall of the house. Into this, doubtless, a whorl of feeders from a portion of the stem above ground has spread. Now, here is an example of the "extension system" of grape-growing in combination with pine-growing, and of long-lived and healthy vines producing heavy crops, whose border is little else than a hard gravel road, from which the genial influences of light and air are nearly altogether shut out. We leave our practical readers to draw their own inferences, merely suggesting the inquiry—Are we altogether right in pinning our faith for lasting results to the rich, elastic, non-compressed modern vine-border? We are well aware of the wonders produced by such for some years; but a certain solidity and poverty, such as characterizes the virgin soil, is we fancy, more favourable to permanent health and continued fruitfulness in vines, and other fruit-trees as well. We were not able on occasion of our visit to ascertain when these vines were planted, or the exact reason for their being placed in such apparently unfavourable situations. Should this meet his eye, perhaps Mr. Brady will, notwithstanding the many urgent calls on his time, kindly favour us with particulars. We may further remark that, in the melon pits alluded to above, we saw the most extraordinary crops of fruit that, perhaps, ever came under our notice.

—*Irish Farmer's Gazette.*

ENCLOSURE OF COMMONS.

It does not appear that there exists any diversity of opinion worth serious consideration in respect of the desirability of preserving for ever, for the use of the public, the various commons and forests immediately surrounding the metropolis. Lords of manors admit the desirability, though they may question the justice, of specific proposals relating to acts of enclosure, and commoners sharing with them in rights of pasturage, common in gross, and other advantages, are, as a rule, not deaf to the clamour of the million for unrestricted enjoyment of the few open spaces that remain. The great difficulty is to decide how these several rights are to be disposed of in favour of the assumed right, the almost indefinable right of the public to range free and wide over unenclosed wastes. Some time since Mr. Peek, of Wimbleton House, offered prizes for essays on commons preservation, and a set of six good essays, written in competition for the prizes, have been published by Mr. Sampson Low, of Ludgate Hill, and with these before us we are not at all prepared to say that the difficulties that beset the subject are cleared up. The great stumbling-block is the fact that in England a lord of the manor enjoys rights defined by the law, but the public have rights which apparently are only defined by sentiment, and the difficulty is to render sentiment subservient to statutes or harmonious with them. But there is another difficulty of perhaps a more serious nature, and it is this, that the public hold fast to the opinion that wherever there is a waste on which cricket may be played and where picnic parties may wander and bivouac without let or hindrance, it is a veritable No-man's-land, and that whoever fences it in or excavates foundations for houses may be made to pay a terrible penalty under some mythical edict of the Court of Chancery. It is a matter of fact that every inch of land in the country, not ostensibly the property of the Crown, is strictly private property. The "Queen's highway," as we term the common road, is private property, and it is simply placed beyond private control because by long usage the representatives of public interests—the parochial board, the highway boards, the corporations, the Commissions—have acquired on behalf of public interests, the sole right of its management. Once upon a time Cheapside was a part of a private estate. So of every road everywhere. So in the present day of all commons and wastes. We may roam over them freely, but the lord of the manor has rights superior to ours, and we may see the proof of it in the gravel pits, the pollarded trees, the draining of meres, and the work of felling and planting of trees. It is also a fact that landed property of all kinds is held in subjection to the Crown; the Queen is the first proprietor, the lord of the manor the second. The commoners take next place, and nowhere in the books is there a place for that indescribable and mythical proprietary, the general public. In every case of investigation of this subject, some attempt has been made to prove the existence of rights on behalf of the general public, without effect. The case breaks down somewhere, and we have at last to face the difficulty of reconciling a public wish with a legal requirement. Take the case of Wimbleton Common. Lord Spencer has rights there that sentiment can never overrule. He offered to fence in and convert to a park a large proportion of that property on condition that another part should be sold. He was compelled to abandon the proposal, but his rights remain intact. We come, therefore, to the very commonplace argument, that if the public want to roam over Wimbleton Common or any other such waste, the lord of the manor and the commoners must be compensated. We are well aware, however, that the means of compensation exist in the soil itself, and that therefore a grant of money from the public exchequer is scarcely needed. All the great wastes, the picturesque bits that so much delight artists and botanical wayfarers in the suburbs of London, are valuable as building sites, and the settlement of the matter in any particular case seems to lie in the apportionment of so much of the whole for building to pay for setting apart the remainder for public use for ever. This may appear a very prosy and perhaps venal method of meeting the difficulty, but we are keeping the law in view, and we are very much impressed with the fact that the six essayists just referred to have quite failed to establish the right of the public to free and unrestricted use of any waste land whatever.

But there is another consideration of some importance. None of the wastes around London can long remain as they are. The very use of them as recreation grounds must tend directly to their ruin in the long-run. Gipsying is not favourable to the longevity of trees. Butterfly-hunting and black-berrying do not tend to the conservation, in all their aboriginal wildness and beauty, of any common or forest land. The more they are used, the sooner they are worn out. Epping Forest (what remains of it) is being used up by the public. If a big tree can anywhere be found, a fire is made near it; or, if it is hollow, within in; and the grass all around is sooner or later strewn with broken bottles. Hampstead Heath is fast becoming a mere dirt-bed. Wimbleton has been in great part spoiled by rifle ranges. It is impossible

to preserve for any length of time a bit of unadulterated forest in close proximity to a densely populated city like London, and the only sober way to look at the matter is to consider how the lawful owners of the soil can be paid out; and next, how the land can be decently raised in, and kept respectable in turf and trees, and, if need be, in flowers also.

During the twenty years ending with 1865, no less than 3,250 acres were enclosed within a circle of fifteen miles of St. Paul's. By the Act passed in 1866, enclosure is forbidden, but the same Act authorizes levelling, draining, and "improving" of common lands within fifteen miles of St. Paul's; and we do not need to be told that those operations are antagonistic to the preservation of wild scenery and the *al fresco* enjoyments that are understood when we speak of unrestricted public enjoyment. To be still more plain, the law knows nothing of the public in these matters. It recognizes ownership in connexion with individual signs and seals, with the argument of inheritance or purchase for the proof of right to occupation, and it would decree any day consistently with such arguments that if any public right were established, trustees would be required, in order that signs and seals might satisfy its exigent prescriptions.

It would be most lamentable if, in the midst of a debate, making no promise of an end—in the prosecution of a cause on mythical foundations—we were to lose Hampstead Heath and Wimbledon Common and Epping Forest. Better far that we should face the facts, and go to work with the idea of compensation for a groundwork, rather than hope to wrest from lawful owners that which cannot be wrested, and to which the public have no absolute claim. There is a claim, no doubt, but it is relative, not absolute; let the claim be so enforced; let us save, if we can, the few breathing-grounds that remain, and waste no more time in attempting to prove a mere hypothesis in which there is not a single fact to be found to support. We would even desire more than the preservation of the existing wastes. We should like to see many noble properties contiguous to them secured for public enjoyment, and for the adornment of the capital with a belt of rural scenery. London is happily surrounded with glorious country. Hills rise above it on every hand, except in the line by the Thames. These hills are well wooded, and abound in picturesque scenery. By timely action, and by recognition of the written law at every step, much may yet be done, and we hope the Commons Preservation Society will adopt new tactics, and take resolute measures to confer upon the public the boon of open spaces secured for ever, without the shadow of a wrong to either the wealthiest or the poorest of those who at present have inalienable claims upon them.—From the "City Press."

Calendar.

WORK FOR WEEK COMMENCING SEPTEMBER 28.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—This is a time for earnest work in every department. Make a general clearance of the ground wherever there are vacant spaces, and ridge up all plots not to be planted on during winter. Get a waste corner clear for heaping up manures and composts, where they can be turned over during frosts, and if convenient empty the muck-pit, and cover the rotted stuff with a layer of soil to throw off rain; the whole to be turned two or three times before using it in spring. In preparing for next year's crops, trench over first the ground intended for root crops next season, and choose for potatoes, carrots, parsnips, and beet, plots that have been well manured this year. If the soil allows of deep digging, fork over the second spit, and if it is of a friable and fertile nature, bring it to the top, so as to turn the whole soil over eighteen inches or two feet deep. Plant out the August-sown cabbage; leave the weakest in the seed-bed for future planting. Plant out lettuce in a warm situation; take up potatoes, carrots, beets, and parsnips; earth up celery. Use the fork, spade, and hoe as much as possible to keep all plots clean, and destroy the large crops of weeds that the autumn rains will bring up. Lay cabbages and broccolis that are forward with their heads to the north. Cauliflower plants to be transplanted into frames, or under hand-glasses. In cold and wet districts, it is best to pot them to winter them in frames, to be turned out into beds of rich soil in spring. In undrained soils, it is a good plan to cut a few channels among standing crops, to enable the heavy rains to run off more quickly to an outlet, as dryness of the ground very much lessens the effects of frost. Fork over asparagus beds, and clear away all litter; remove the stems with a knife, and dress the crowns with manure, and a little fresh mould over all. This is the best time to make plantations of rhubarb for producing next season. Let the ground be deeply dug and well manured. Tomatoes not ripe should be cut with a length of stem, and put in a warm greenhouse where they will soon ripen.

ASPARAGUS to be cut down to the surface of the ground, be well cleaned, and covered with four inches of half-rotten dung. The spade must never be used, either on the beds or in the alleys.

CAULIFLOWERS to be planted out under frames and hand-lights, and some potted as previously directed. If there are many plants still left in the seed-bed, prick them out on a warm slope, or make up a raised bed for them, so that they can have the protection of mats or hoops during sharp weather.

BROCCOLIS in exposed places may be heeled over to be safe against the first frost; stir the ground between them, but do not earth-up the stems.

CABBAGE sown in August to be planted out as soon as ground can be got ready. In sheltered places manure may be used liberally, but in exposed districts it may cause too free a growth before winter, if the plants are to stand.

RHUBARB to be forced may now be taken up and laid on one side until it is time to put in the boxes or whatever other position it is to occupy when forced.

VACANT PLOTS in kitchen and flower garden to be turned over at once, and, if needful, manured. All heavy land which is to lie unoccupied till spring should be ridged up without breaking the clods. The autumn rains and winter frosts will mellow and fertilize the soil, and in spring every clod will break down into powder at a touch. Heavy land may be manured if convenient now, and very little will be lost; but light soils should not be manured till spring, unless they are at once to be planted, as from these soils the heavy winter rains will wash away much of the manure. Prepare tulip beds at once by frequent turning, and mark out plots intended for rhubarb, scakale, asparagus, &c., so as to have them deeply trenched in good time to be acted on by frost.

Flower Garden.

FLOWER GARDEN.—Let *Chrysanthemums* be securely staked; train out plants in pots, and make them neat and tidy for blooming; give plenty of water. When required to take the place of bedding plants, get them into their places without delay, and lift carefully with good balls. *Chrysanthemums* in the borders should be looked over without delay, to see that they are sufficiently staked, for heavy rains and winds play terrible havoc with them when they are not well supported, owing to the profusion and weight of their blooms. Where they are required to take the places of bedding plants, they should be got to their places at once, and be lifted with good balls, and well watered in. Choice and delicate sorts are best flowered in pots under glass, and for this purpose they ought to have been potted one or two months ago, and shifted as required, and trained out so as to give effect to their beauty when in bloom. The bulbs to be planted this month are *Ilyacincths*, *Crocuses*, *Scillas*, *Crown Imperials*, *Liliums*, *Iris*, *Narcissus*, *Jonquils*, *Daffodils*, and early *Tulips*. Next month is soon enough for late *Tulips*, and *Anemones* and *Ranunculuses* are best kept out of the ground till February, except in places where autumn planting has been proved to answer for them, in which case it is preferable. Herbaceous spring flowering plants may also be got into the borders, to bloom at the same time as the bulbs—such as *Wallflowers*, *Primulas*, *Polyanthuses*, *Arabis*, *Alyssum*, *Aubrietia purpurea*, *Pansies*, *Dielytras*, *Iberis*, &c. Get all plants of questionable hardiness, and any that are liable to suffer from wet or the attacks of snails, under cover. Choice alpine are more easy of preservation if potted and put in frames. *Auriculas*, choice *Pansies*, *Carnations*, *Penstemons*, *Brompton* and *Intermediate Stocks*, *Myrtles*, and even *Hollyhocks*, if the situation is a damp one, must go to similar quarters for the winter, and have plenty of air in mild weather. Remove decayed leaves wherever they occur, to prevent the formation of moulds about growing plants.

BULBS of all kinds to be planted in beds and borders. *Pot Hyacinths* in succession, so as to prolong the season of blooming.

CHRYSANTHEMUMS to be attended to, so that they may have a fair chance of making a good bloom. Give them clear liquid manure, and stake them securely, as their blossoms being heavy, often weigh down the stems, or cause frail sticks to snap with a gale of wind. Do not house any so long as they are safe from frosts, except any that require forwarding to get them in bloom by a certain date. Artificial heat will do wonders to bring them out quickly; we have known them submitted to a temperature of 80° or 90° at this time of the year; but it should never be resorted to if it can be avoided, for it has some prejudicial effect on the colours of the flowers.

TULIPS to be sorted over, and arranged for planting. In a bed of fancies, be particular as to heights, as it spoils a bed to get first or second row flowers into third or fourth rows. Contrasting the colours is of far less consequence than getting the heights correctly, and some sorts grow taller or dwarfer than they are marked in the catalogues, where any peculiarity of soil affects them. Border and bedding *Tulips* should be ordered in quantity at once.

CARNATIONS potted last month will require to be looked over to remove dead leaves, and to see that mildew is not attacking them. Keep them well aired.

AURICULAS to have plenty of air, and be protected against damp, which is apt to injure them as the weather grows chilly.

DAHLIAS require a good deal of care now to keep them trim, and as flowers are getting scarce, let the *Dahlias* have necessary attention to keep them gay to the last. Make up your list of varieties for next year while the varieties are in bloom, and throw out every one that has not realized your expectations. When there are so many good ones, it is a folly to tolerate any that are of questionable merit.

EVERGREENS planted now will make better growth next spring than those planted in February and March. Give orders at once for all trees and shrubs required, that there may be no delay in obtaining them as soon as the nurserymen begin to take them up. All small subjects may be taken up at once in full leaf.

HOLLYHOCKS of the best sorts to be propagated to keep up a good stock. They should be renewed by cuttings every year.

Fruit Garden and Orchard House.

FRUIT GARDEN.—Towards the end of the month, gooseberries, currants, and raspberries may be moved. New plantations should be made on ground deeply trenched and manured; gooseberries and raspberries need a richer soil than currants; and black currants and raspberries will thrive in more marshy ground than any other of the bush fruits. In all removals, whether of trees, bushes, or herbaceous plants, let the roots be examined, and all diseased or mouldy portions cut clean away.

CURRENT AND GOOSEBERRY canes may be put in to increase stock, and for this purpose two-year old wood is better than the shoots of the season if disbudded a foot or eighteen inches from the base. Drain and trench the ground where fruit-trees are to be planted next month. Moss on apple-trees generally disappears when the ground is drained. Root-pruning and planting may be commenced the last week; but root-pruning should only be resorted to in the case of over-luxuriant, unfruitful trees. In planting fruit-trees, unless the soil is poor and exhausted, use no manure whatever; pure loam is preferable to an enriched soil for all trees intended to bear early and live long. You need not wait till next month if your ground is ready; trees may now be moved, even if they have not shed their leaves, and will make fresh roots immediately.

APPLES to be carefully gathered as they ripen, and to be stored at once without wiping them. This is a convenient time to cut out dead wood.

Greenhouse and Conservatory.

GREENHOUSE.—House at once whatever is to be wintered under glass. Remove the shading, give plenty of air, and whenever green-fly or thrips appear, resort to effectual methods at once, and much future annoyance will be saved. Plants that are to bloom during the winter should have the best place as to warmth. Give plenty of air, day and night, and remove the shading, so as to let in all the sunshine that can be had. Avoid making up fires; but when it becomes necessary to do so, make a brisk fire so as to dry the house and promote a current of air; otherwise, push nothing into growth more than may be needful to ensure vigorous health and plenty of stamina. If mildew appears, use flowers of sulphur; for green-fly, tobacco smoke. If aphides get possession of the tender crowns of cinerarias and fairy roses, and smoke fails to dislodge them, turn the plants upside down into weak tobacco water, and then lay them on their sides, and syringe them well with soft tepid water.

FUCHSIAS may be kept in bloom till very late in the season by keeping them rather close and warm. Plants going out of bloom, and which are to

be grown another season, should be put out of doors to harden them, and left unpruned till they have tasted a very slight frost; then cut them in slightly, and house in any moderately dry place, either light or dark, till they begin to break in the spring.

GERANIUMS newly struck will require to be kept rather warm to encourage the formation of roots; those that are strong in pots may have plenty of air, and be kept rather dry to check growth. If more geraniums are wanted, put in the ripest shoots you can get, five or six round the sides of 5-inch pots, and place them on a top shelf. They will root in time, though slowly. Of course they must be kept moderately dry.

CINERARIAS should be kept growing freely, and be regularly stopped to produce good specimens. At this time of year they are very subject to mildew and green-fly. Use the proper remedies as soon as there are the least signs of such plagues, and keep the plants well aired to induce robustness. Keeping the outsides of the pots clean will do much towards ensuring their health.

PERLAGONIUMS for spring exhibition will now want another shift. Get them into their blooming pots at once, use good turfy loam and old manure, plenty of drainage, and for a fortnight after shifting give very little water.

BEDDING PLANTS may still be propagated, but the stock ought to be complete by this time. Calceolarias put in now will make good plants for bedding next summer.

AZALEAS AND CAMELLIAS standing out should be got under glass at once, but still to have plenty of air. Those coming on for bloom will require frequent syringing.

REVISE the whole stock of plants in pots as opportunities offer to remove worms from pots; renew the drainage where it has got stopped up, and otherwise prepare for the casualties of winter. Greenhouse plants that have been standing out must now be housed, and those to be forced must be repotted if needful.

Stove and Orchid House.

ORCHID HOUSE.—As the season declines, the temperature of the house must be reduced, but this must be done with great care, because many fine species will soon be showing bloom. In the first place, look to the Cattleyas, and remove them to the coolest end, and let them have a temperature averaging 70° by day and 60° by night, in order to induce a perfect state of rest. If in a higher temperature than this, there will be a further growth of the plants at the expense of the next bloom. With these group Cynoches, Lycastes, and Catasetums, which are all likely to suffer if kept growing now in too high a temperature. Orchids now pushing for bloom will require liberal heat and moisture, and these may be grouped with Dendrobiums and Aerides in a temperature of 80° by day and 70° by night. As soon as any of the Barkerias, Cynoches, Cyrtopodiums, Phajus albus, Pleione maculata, Wallichiana, and other deciduous orchids begin to shed their leaves, they should be placed in the cool end of the house in the most sunny position that can be found for them, and there have but little water. This treatment will cause them to ripen their pseudo-bulbs, and their after growth and flowering will be more vigorous. On the other hand, Vandas, Angreecums, Aerides, Saccolabiums, and Phalenopsis must never be allowed to get very dry at the roots, even when at rest, as they shrivel and lose their lower leaves. These species, moreover, require but a short period of rest. Variegated orchids require great care from this time till March; only give enough water to keep from shrivelling.

ORCHIDS THAT MAY BE IN BLOOM IN OCTOBER: Angreecum bilohum; Barkeria Lindleyana; Bletia campanulata; Burlingtonia Knowlesii; Calanthe vestita rubra oculata; Cattleya candida, guttata, Harrisonie, intermedia superba, marginata; Cypripedium Farrieanum; Dendrobium Gibsoni, Heyneanum, sanguinolentum; Huntleya Wailiesii; Lælia elegans var. Dayii, furfuracea, Perrini; Miltonia candida, Clowesii major, Morelii, Regnellii; Phalenopsis amabilis, grandiflora; Pleione maculata, Wallichiana; Stanhopea oculata; Vanda Lowii.

VINES breaking to be encouraged with a temperature of 60°. Beware of too much heat in theinery this month, for any excess will cause vines to push too fast for the amount of light they get. Give air freely on fine days, and keep a sharp look-out for vermin of all kinds, which at this time of year frequently do much damage before they are suspected. Where grapes are desired to be kept hanging, a very dry air must be maintained; hence plants in pots that require frequent watering should not be kept in the same structure till the grapes are off. Prune the vines that are to be started first, and clean the stems. Keep the sashes off till about the 20th of the month, and then put them on, and cover the border with leaves and sloping boards.

Forcing &c.

CUCUMBERS to fruit during winter should be grown strong before being allowed to flower. Do not stop them severely, but take a few strong runners along the trellis, with full exposure to the light, and with a liberal moist heat to ensure a luxuriant growth for the present. If any signs of mildew, apply sulphur without loss of time.

Literature.

Studies, Biographical and Literary. By G. Ross, M.D. Simpkin, Marshall, and Co.—This book is evidently the result of the meditations of a scholar and thinker, to whom publicity is of far less importance than the pleasure of expounding his views, and communicating his speculations to an earnest few who will be likely to appreciate them. Dr. Ross may rest assured that the few who love pure literature and original thought will discover this book, and prize it as a treasure, for, unlike the "essays" that abound in current literature, none who have read these will desire to forget them, but will pass them on from hand to hand until the circle of the most elect in literary matters shall regard Ross's "Studies" as one of the best books of modern times. The volume opens with a sketch entitled "A Scene in Hades." This is followed by an essay on the mad characters in Shakspeare's works, and there are elaborate critical papers on Dr. Johnson and Sir Walter Raleigh. The Shaksperian paper is the gem of the volume, perhaps because Dr. Ross's professional experiences peculiarly fit him to deal with so difficult a subject as the delineation of madness in dramatic character, but perhaps also because Dr. Ross is gifted with a critical insight above and beyond his own speciality in life, and knows much more of Shakspeare altogether than many a more pretentious and voluminous critic.

Pinacæ: being a Handbook of the Firs and Pines. By SENILIS. Hatchard and Co.—Having a great desire to speak kindly of this work, we long ago set it aside for a leisurely examination, in the hope of finding in it some useful information, some original ideas even, or in some way or other a com-

penetration for the absurdities that force themselves upon the attention of the reader in every attempt made at a perusal. Well, to say that the book affords no useful information would be unjust; but in this respect it gives us nothing that has not been as well done before, and there is no compensation for the twaddle, pedantry, and pompous conceit the reader must bear with who would read the book through. "Senilis" has not acquired wisdom with years, and, like a wheat-stalk that bears no good grain, we do not set a high value on his chaff.

The Floral World and Garden Guide. Edited by SHIRLEY HIBBERD. In recent issues of this monthly work have appeared papers on Window Gardens, the Uses of the Ivy, the Culture of Adiantums, Skimmias, Equisetums, Dahlias, the Orange, and other plants; also papers on the cropping of the kitchen garden, on the plunging system for villa garden decoration, and on the preservation of bedding plants during the winter. The descriptions of new plants, accompanied by figures, has become one of the best-appreciated departments of the Floral World.

The Intellectual Observer has been rather heavy of late, though fully up to the mark in scientific value. The pictures, too, are as beautiful as ever. In the August and September numbers occur papers on the Fungi of India, by the Rev. M. J. Berkeley; on the Ferns of Glen Clova, by Henry Woodward; on the "Pottery-tree" of Para, by Mr. Jackson, of Kew (with figures of the vessels formed from the siliceous bark of the tree); the Food of the Salmon, by Mr. Houghton. Besides these Mr. Proctor and Mr. Browning contribute astronomical papers, and the gatherings of scientific news are full of interest for all classes of readers.

The Gardener, edited by WILLIAM THOMSON, continues to be fresh and spirited as ever. The papers on the Flower Garden are admirably done; the Editor's notes of a Trip to Manchester will interest many. There are capital papers on Eucharis amazonica, the Yucca, Chinese Primula, Cape Heaths, Hardy Herbaceous Plants, and Fruit-tree Borders.

The Ladies' Treasury, edited by MRS. WARREN, is undoubtedly the best book of its class, and, strange to say, there are very many "ladies'" magazines and newspapers competing for the favours of the fair sex. The thought occurs to us, as it did when we were noticing a hook for Sunday reading, which was published not long since—why get up books for such special purposes? Why offer a book particularly for Sundays in one case, and for ladies only in another? It is a mystery; we leave it to some more subtle critic to prove its depths. May a Sunday book be read on a week day, and if any book is fit to be read on a week-day, is it not fit also for Sunday? Again, are men permitted to read the Ladies' Treasury? and if so, may ladies read, without dread of shame and ruin and misery, the magazines and newspapers that are commonly read by men? We simply ask these questions of any *Edipus* who happens to be passing, with a promise that he shall not be eaten if he answers them. While waiting for the answers, our readers are at liberty to purchase the *Ladies' Treasury*, and we really expect all our lady friends to do so, for we wish them to know all about the latest fashions, that fathers and husbands may renew the joys of providing for mercenary mercenary bills.

Our Own Fireside, edited by REV. C. BULLOCK, is full of life, variety, more original than in its earlier history, and aiming always at the highest culture and the purest ethics. Mrs. Ellis contributes some charming papers on home affairs, the papers on Arctic Adventure are continued, and the Rev. F. O. Morris pours out of his (apparently) exhaustless budget those charming stories of animal intelligence and sagacity, which have done so much to make *Our Own Fireside* one of the most welcome of the monthlies.

RECEIVED.—*Speculations on a Method of Extinguishing Fires without Water*. By F. W. Devey. Effingham Wilson.—*The Journal of Botany*. Edited by Dr. Sceman.—*L'Illustration Horticole*. Edited by M. Lemaire.—*The Gospel Magazine and Protestant Beacon*. Edited by Rev. D. A. Doudney, D.D.—*The Watchmen of Ephraim*. Edited by John Wilson.

Correspondence.

BIRDS AND THEIR NESTS.—Have any of your readers observed elsewhere the fewness of birds' nests this spring and summer, which has certainly been most remarkable about here? This rectory is thickly surrounded by trees, and in other years birds of various kinds, being always unmolested and undisturbed, have built their nests and reared their young in numbers—greenfinches in every corner, blackbirds only too many—the black-cap, the garden warbler, the thrush, the mistletoe thrush, the wren, the spotted flycatcher, the willow warbler, the chaffinch, the duncock, the ox-eye, and on one occasion the golden-crested wren; robins, starlings, swallows, martins, and sparrows of course, wagtails; the partridge, too, within half-a-dozen yards of the house, the white-throat till some bushes in which they built were cut down, and, just outside the fence, the chaff-chaff, the yellow-hammer, and the whin-chat. This year I do not believe a single greenfinch has built here, not more than one pair of robins, one or perhaps two of flycatchers, one of ox-eyes, one of black-caps, one of wrens, one of blackbirds, also a pair of redstarts, the first that ever built so near. I have only seen one young thrush about, and even that may not have been reared in the grounds; comparatively few sparrows, and no others except martins, starlings, and swallows. One pair of the last-named built on a rafter in the stable, but though I had the door left open all night that they might "have their exits and their entrances," and though the birds roosted close by the nest every night, no eggs were laid until September. The south side and east end of our ancient little church used to give many a "coign of vantage" to the "temple-haunting marmlet," but this year not a single pair has domiciled there. Of the several pairs which likewise used to build over the windows in the front of the house, this year, being disturbed by the painters, none returned to it again, but in the back of the house there are seven nests. Our fruit, of which we have had the most extraordinary quantity I ever saw, was well protected with nets, but there has scarce been a blackbird to run the blockade. In the winter we had one with a white tail in the garden, looking like some foreign bird, but the very hard weather we had took him away, and we have seen nothing of him since.—I am, sir, your obedient servant,

Nunburnholme Rectory, Heyton, York.

F. O. MORRIS.

SHANKING OF GRAPES.—In your issue of the 14th inst., page 400, the subject of diseased vines is treated. I beg to inform you that I have a house which is in the same position as that referred to by E. H. A. My opinion as regards shanking in grapes is that it is more to be attributed to the border being wet than any other cause yet known. In my experience as a gardener, I have practised keeping a vine border as dry as possible

with the lawn mowings, and thatched with straw, say from now until the end of April next, then taken off and a light dressing of rotten dung forked in. By so doing I believe the air can get to the roots, and the wet be quite excluded, which I consider to be the great cause of shanking, and my belief is that manure allowed to remain on the border will rather tend to increase the disease than otherwise. Am I right?

W. WHITTINGHAM.

Chedde. You are right, if the vines are in a wet soil; but suppose them to be in a thin gravelly loam over chalk, or otherwise in a permanently droughty place, then the case would be different.]

ZONAL GERANIUMS AT THE MANCHESTER EXHIBITION.—In your excellent report (page 383, Sept. 7) of the late Manchester Horticultural Exhibition, speaking of the collection of variegated pelargoniums which won the first prize, you say, "The collection contained only one variegated plant according to commonly received notions, the rest were bronze zonals, some of them with so much green in the leaf as scarcely to surpass in respect of leaf colouring the old Commander or Cerise Unique." *Bridesmaid* appeared to be the only variegated plant in the group, according to your report; but how is it that the fine plant of *Florence* is not considered variegated. This without doubt is one of the best tricolors in cultivation, and having at least four distinct colours in the leaf. It was admitted by all who saw it that there was nothing in Mr. Watson's collection to equal it. One of the plants you refer to as being so green did not belong to my collection, but to Mr. Watson. The plant was placed just in the angle of the bank between Mr. Watson's outer row and my group, which stood behind his. I was certainly annoyed at his placing it there, as I was sure it did his collection no credit, and was a disgrace to mine. What could have induced him to bring a plant having so little to recommend it all the way from St. Alban's to Manchester puzzles me. I consider there was nothing in Mr. Watson's lot worthy the recognition they received; five out of the eight kinds were so much alike as to make it impossible for any one to tell one from the other; the plants were also badly grown. Mr. Watson staged his plants in such a clumsy way, that even if they had sufficient merit to recommend them for a second prize, they ought to have been disqualified on that account. I was surprised to see so little taste displayed by an exhibitor who has travelled so much, and who has had such frequent opportunities of seeing plants staged in a proper manner both in London and in the provinces. I trust this remark may be the means of causing him to show more taste in future.

JOHN WILLS.

Huntroyde Gardens, Burnley, Sept. 11, 1867. [Mr. Will's plants were reported on precisely as they appeared. From the foregoing explanation it seems that they were in some way or other mixed up with the plants of another exhibitor. If such was the case, who was to blame? It is quite certain that when I made up my book there was but one variegated plant in Mr. Will's group. Now, Mr. Will, did you stage more than one, or did you remove some on the first day of the show? The criticism on Mr. Watson's lot is uncalled for, and by no means in good taste. It is not at all nice to see one exhibitor detracting from the merit of another in the same class. Prudence would suggest in such a case either approbation or silence.—S. H.]

NOTE ON VINE-GRAFTING.—In the vinery at Cranwells, near Bath, the seat of Jerome Murch, Esq., may be seen two vines that were grafted in the middle of March last which have made remarkable growth. The first is a Buckland Sweetwater grafted on White Frontignan; the length of growth to the present time is 20 feet, and the girth of vine 2 feet above the graft $2\frac{1}{4}$ inches, with leaves 14 inches in width. The second is Lady Downes' Seedling, grafted on a worthless vine, supposed to be a seedling. This also has made luxuriant growth, and promises well for next season. The length of vine from graft to the present time is upwards of 20 feet; the girth 2 feet above the graft 2 inches, with leaves 15 inches in width.

W. W.

SCARLET-BERRIED ELDER.—Communications have occasionally appeared in your very useful publication respecting the *Sambucus racemosa*, or scarlet-berryed elder. All your correspondents agreeing in its extreme beauty as a berry-bearing shrub, as it is met with in many parts of Switzerland and Germany, and being perfectly hardy, there seems to be no reason why it should not be extensively cultivated in England, and, it may be added, in Scotland, Ireland, and Wales—that is, generally—but the serious drawback which arises from its early flowering—with us usually in March—when, though it forms its berries freely, they too generally either fall off or are otherwise destroyed by adverse weather. For two successive years, however—that is, last year and this—some berries have remained and ripened on a shrub in my garden, in the neighbourhood of London; and not only so, but this year, in July, this shrub partially reflowered, forming little clusters of berries, which have ripened, and are now of a bright coral colour. Thus, I think, it is clear, and this mainly leads me to trouble you with this communication, that if this shrub, by cultivation in this country, should so far become acclimatized, as to the time of flowering, as to do so about the period that our common elder does, then there can be no reason to doubt that as a highly ornamental shrub it would become of that priceless value in this respect which one of your correspondents claimed, and justly, for it. At any rate, as it is easily propagated, either by seeds or from cuttings, it is well worth the experiment.

A. Z.

Replies to Queries.

Retlow maharg.—To make your pit safe you want a three-inch or a two-inch pipe round the two ends and front. No doubt some warmth is abstracted from the adjoining house, but in front it is too much exposed to the east to be safe for bedding plants. The simplest way of proceeding would be to carry a pipe from the flow on that side round the pit; the cost would be trifling, and it would not distress the boiler. It is not a pleasant task to recommend any particular boiler, now that there are so many good. One of Lynch White's upright conical boilers, set in brick-work, would suit your case admirably. You are, of course, aware that a boiler set in bricks does not cool down so quickly as one to which the atmosphere has free access.

Subscriber.—No; you cannot, with any justice to yourself, plant a bed of asparagus this autumn, and cut from it next spring, on a cold, damp, stiff soil; but you may prepare the bed now and plant next spring, and cut a few heads in the year following.

Roses.—Rosarian.—The honey-dew is the excrement of the aphides; therefore, whatever will make an end of aphides will make an end of honey-dew. Having had much practice with roses, you will not want a recipe; but if

you have not yet tried the Aphis Wash of the City Soap Company, it would be well to bear in mind that it is an infallible specific. We regret that, owing to continued absence from home, your letter did not obtain earlier attention.

Fruit Border.—Yorks.—The stone flag under each tree will be a great assistance to the growth, and will prevent the roots going down into the mischievous clay. The fifteen inches' depth of loam will not be enough; increase it to twenty-four inches by adding turf, if you can get it; if not, increase the depth by adding more of the same loam, and with it a liberal dressing of manure. The breadth should be six feet at least.

Kent.—Plant your trees in the houses six feet apart, and by pinching back keep their heads from mixing. Hayco's Constant Stove would afford enough heat for a house 30 feet by 14 feet to mitigate the effects of frost in spring. But the best mode of keeping frost out would be a small conical boiler and four-inch hot-water pipes.

W. H. K.—Your seedling from Souvenir de Chiswick has the character of an improved Alpha, and that is not a bad character. The flower is large, sepals broad and thick, coral-red, corolla inclining to sugar-loaf shape, petals broadly overlapping, reddish purple. Get some friend to grow a specimen plant of it, and in the mean time do the best you can with it in the window.

Mr. James Kirtland, Albion Nursery, Stoke Newington.—Your seedling dahlia, "Australian Gold," is a large flower, of fine symmetrical form, and capital centre; the colour clear pale yellow, quite distinct from others in its class, and very nearly the same shade as the Australian sovereigns that have lately come into circulation.

Piney.—Keep your house at about 45° to 50° all winter. It is very difficult to remove scale from a fern-house. One of the first steps should be the cutting and burning of all old fronds that are much infested. The next business should be the removal by hand of all the scale that can be found on the young fronds that remain. The next process is to fumigate with tobacco; this must be done frequently and cautiously.

Constant Subscriber.—It would be well to consult the "Garden Oracle" for 1866 before ordering any ferns.

G. B., Bradford.—From your account, we think your garden is much more in need of abundant manuring than of liming. But if you intend to apply lime, let it be done just before trenching the ground up for winter, and again just before making up seed-beds in spring. You may be pretty sure the lime will do more good than harm; in fact, it cannot do harm. The waste of the soap factory is a good manure, but it must not be allowed to come into contact with growing plants.

G. O.—Order it of any bookseller. Our copy has gone the way of all newspapers, and we cannot now discover the publisher's name.

H. G.—The "stout but flowerless rods" that rise from "own-root roses" should be allowed to remain their full length till the following spring, and then be cut down about a third of their length, or to any height that may be consistent with their position in the garden, and they will flower abundantly. The whole subject shall have immediate attention.

Working Man.—Four to six inches of good peat, with a fifth-part of silver-sand added, will make a good bed for the ferns. Do not attempt to heat the case, because you can have plenty of beautiful ferns that require no heat. Look to the "Garden Oracle," 1866, for a suitable selection.

Beds. Cottageer.—1. The best carrot for your clay soil is the Scarlet Intermediate. Trench the ground two spits deep at once, and lay it up in ridges, and in April next level down and sow. 2. Common hollow-crown parsnip will be the best, and the cultivation to be the same as for the carrot. 3. For what purpose do you want the potato? If for summer use, Grimsdale's Early and Smith's Early are the best; if for storing, White Radical and Flour Ball. 4. Enfield Market cabbage. We never recommend seedmen.

C. V.—It is most likely that the pest you have to deal with is red-spider; and we strongly suspect you keep your plant too hot and too dry. Alter your practice in these respects, and no doubt you will have better fortune. Your other query can be answered by reference to our advertising columns.

Books.—S. B.—Purchase Thomson on the Vine, price 5s., and do not look after any other book on the subject till you have mastered its contents. Hibberd's "Rose Book," price 5s., will give you every needful information on every method of propagating. The "Hortus Kewensis" you must inquire after among the second-hand booksellers. Try Wheldon, Paternoster Row.—Sigma.—The botanical articles in the "English Cyclopaedia" are of no use to one who proposes to engage in a thorough study of botany. We have been much disappointed with them, even for the most ordinary purposes of reference.—W. W.—Do not waste your money on the Fleet-Street books; they are sad trash. Secure Mr. Smith's book on Ferns, published by Hardwicko.

PROMOTION OF THE TURNIP.—A great promotion has fallen on the turnip. A little while since its destiny was to furnish lantern-heads for ghosts. Now it is to supplant the pine-apple. Some ingenious Parisian confectioner has devised a syrup which changes the ordinary turnip into a pine! What next? We shall have apples turned into apricots and potatoes into plums. This comes of the democratic tendencies of the age! If we can make baronets out of WENTWORTH DILKES and C.B.'s out of COLES, why not pine-apples out of turnips?—*Fun.*

THE LESSON OF THE GARDEN.—A garden is a beautiful book, writ by the finger of God; every flower and every leaf is a letter. You have only to learn them—and he is a poor dunce that cannot, if he will, do that—to learn them and join them, and then to go on reading and reading. And you will find yourself carried away from the earth by the beautiful story you are going through. You do not know what beautiful thoughts grow out of the ground, and seem to talk to a man. And then there are some flowers that seem to me like over-dutiful children; tend them but ever so little, and they come up and flourish, and show, as I may say, their bright and happy faces to you.—*Douglas Jerrold.*

RATS PLAYING AT MAGPIES.—About five years ago Mr. Robert Starkie, of Higham, in the forest of Rossendale, having to leave home for the day, as a matter of caution, placed a bag containing £65 amongst some potatoes stored in one of the rooms. On returning the following day he found that the bag had disappeared, although everything else seemed just as when he left; and subsequent inquiries having failed to elicit anything respecting the missing treasure, he had long given it up for lost. A few days ago, however, owing to a marriage celebration, it was decided to have the room whitewashed, and while this was being done a string was discovered hanging from a hole in the wall. On the string being pulled, out came the missing bag, containing the money. It is supposed the bag had been conveyed to the hole by rats.

The Gardener's Magazine.

SATURDAY, OCTOBER 5, 1867.

THE JUDGING OF GRAPES might at any time furnish an interesting theme for discussion, and for some time past it has greatly agitated the lights of the horticultural world. No one can question its importance both commercially and socially, for under the first head the grape claims our best care as a source of wealth, and under the second, as one of the most welcome adornments of our dinner-tables, exhibition tables, and gardens. Whatever may be our short-comings in fruit-culture, we unquestionably stand first in all the world in the cultivation of the grape-vine, a consequence principally of the fact that it is here unknown as a wild plant, and therefore must always be subjected to artificial treatment. Were the pine-apple a weed of the soil, we should probably know far less about its habits and requirements than we do under the circumstance that it is a foreigner, and will not even live here unless it is the subject of constant care. So, but in a less degree, with the grape-vine. It will live on the bleakest hill-side; it will produce tolerably good fruit if fully exposed to the elements with the aid of the shelter of a wall, but it is only when assisted by glass, and more or less of artificial heat, and with careful tendance in other ways, that the fruit attains to that nobility of size and colour, and that richness of flavour by which the best examples of English grape-culture are characterized. We may well be jealous of our fame, which has been hardly earned, and anxious to save it from tarnish even when foreigners are not observing us. Assuredly the fair fame of English gardeners as grape-growers must be more or less affected by the official decisions of judges at exhibitions on grapes submitted for competition. There is a difference of opinion amongst growers of grapes as to the rules by which judges should be governed; and, with a view to assist in a settlement of the difficulty, we propose to offer a few observations and suggestions.

A bunch of grapes is valued—if valued at all—for two reasons. It is beautiful to look at, and it is good to eat. We look first, and eat afterwards; we never—as a rule—approach it with our eyes shut, and eat what we have not seen; and to see it after we have eaten it is impossible. Between the two opposite poles of appearance and flavour the judges have been long oscillating and vacillating, unable to arrive at any general conclusion or unanimity. We shall not attempt to review or recapitulate the arguments employed on either side, but will just submit to our readers a few facts which may serve to furnish arguments towards a code of judging.

A bunch of grapes of small size, in which the berries are small, in which some of the berries are shanked, in which all the berries are of a bad colour—i.e., green in the case of white grapes, red or rust-colour in the case of black grapes, and wholly deficient of bloom, will not improve the appearance of the house in which it has been grown, the exhibition or dinner-table on which it may be placed, and in the market will be unsaleable.

Grapes are grown to eat; therefore, if grapes are deficient of flavour,—that is to say, of such flavour as is peculiar to good examples of the particular variety tasted,—the value at which they may be appraised in the first instance, on account of size and beauty, is seriously depreciated. We must have flavour, therefore, as well as appearance.

When grapes are judged at exhibitions, the greener samples of white grapes are never so richly flavoured as the yellowest

samples of the same class, and the more the yellow hue predominates in white grapes the better is their flavour; therefore colour is a good criterion in the judging of white grapes. But the blackest samples of black grapes, and those especially that have the most perfect bloom, are not always the best flavoured. Sometimes the reddest bunch of Hamburgs in a competition of a score of examples, from as many exhibitors, will be the best in flavour and the worst in appearance. Therefore colour must not be relied on solely in determining relative value or merit.

In respect to the relation subsisting between colour and flavour, this point must always be borne in mind, that black grapes in perfect condition, as to colour and bloom, but deficient of flavour, will, if allowed to hang on the vines, continue for a long time to improve. In these cases colour and bloom are attained before the flesh is fully ripe, and when the eye has pronounced them perfect, the palate presently declares them imperfect, and therefore flavour as well as appearance should be included in the category of qualities to which we apply the term FINISH. On the other hand, black grapes that are not black, that perhaps are red, but possessing a good flavour, will, if allowed to hang on the vines, continually deteriorate. In other words, they will not hang; they contain more water than black samples, and have already stored up as much sugar in their cells as they are capable of secreting, and the next, and a not far off, stage of their career is decomposition. The same red grapes are deficient of bloom, which is a natural accompaniment of a healthy skin and a firm pedicel, and therefore while their interior pulp is in a condition to undergo speedily a destructive change, so the skin of the berries, having none of the protection which a bloom affords—for that is the use of the bloom—is in a condition to become speedily mildewed, and the pedicels being loosely attached, soon allow the berries to fall. As a matter of fact, red grapes soon become watery if kept on the vines, and on the slightest touch the berries fall to the ground in showers. As a matter of fact, black grapes—grapes of good size, deep colour, and with a plentiful bloom—will hang on the vines for a considerable time without becoming mildewed, without becoming loosened from their pedicels, without changing their contents from sweet mucilage to water, but indeed with a change always augmenting up to a certain point of their keeping, from a less rich to a more rich condition, and to a condition at last far surpassing the condition of highest perfection ever attained by the red grapes. As a rule, grapes that are perfect in colour, but imperfect in flavour, are simply not yet ripe; but grapes from very young vines, produced by rapid systems of cultivation, never have so good a flavour as grapes from old vines, that are neither highly fed nor forced in haste. There is but one way to sum up these considerations with a view to judging, and it is this: that although colour may not indicate what a grape is, it is usually indicative of what it will be, and in the end we shall find, *malgré* occasional exceptions, that colour is of much more importance than it has been commonly regarded in the judging of grapes.

Let us now dismiss quickly a few absurdities that have become entangled with the discussion. One authority protests that it does not matter what the colour provided the flavour be agreeable. We have shown first that colour enhances the market value, enhances the home value, and is to a great extent a criterion of the capability of a grape to keep and improve. Therefore the doctrine that flavour alone should be considered is absurd.

Another asserts that the bloom on a grape is a filthy superfluity, suggestive of mildew, and possibly poisonous. We will not disfigure this page by using an epithet that might betray our lack of politeness, else we should prefer to settle this critic with a single word. But it will suffice to say that Nature puts a bloom on many of our best fruits, and we prefer her ways to the ideas and prejudices of men, even if they happen to be learned men. Somehow we fancy Nature knows best, and if we be pushed for a reason of our faith in this particular instance, we say the bloom on the skin of a grape or a plum has a preservative property, and is intended to keep for our use to-morrow what we cannot eat to-day.

It is urged, again, that appearance is everything, and that the tasting of grapes at exhibitions is a sort of sacrilege. Some very respectable men have taken their stand on this proposal for a basis of judging, and the facts we have advanced

above will show that they are right nearly. They know that however good the flavour, if the colour is bad the grapes will fetch a miserable price if sold at once, that they will soon spoil if kept, and that, except for a blind man's luncheon, they are scarcely capable of affording gratification to any human being. It is no use to beat about the bush; if people possess any sentiment that lifts them into any higher region of aesthetics than that inhabited by pigs, they will take pleasure in the beauty of fruits, and the most beautiful, if good at all, will be the most valued. But we say to the propounders of this doctrine that there are apparent exceptions to the rule, and that to discover the law of such exceptions is of the utmost importance; and, lastly, whatever we may infer as to the flavour of grapes by their colour, an inference is never to be preferred to the determination of a fact, except where the determination is impossible. Now in the case before us there is no impossibility, and we conclude that IN JUDGING GRAPES TASTING SHOULD BE RESORTED TO, AND FLAVOUR SHOULD BE CONSIDERED AN IMPORTANT TEST OF MERIT.

Now let us come to the practical part of the business. It is alleged that many gentlemen object to their grapes being touched, and will cease to show if tasting be continued. To this allegation we reply that competent judges will not handle grapes in a way to injure them, and will not remove more berries than are needful for a determination of relative flavour. If there are three judges, every bunch submitted to competition must be robbed of at least three berries, a small loss, to be sure, and scarcely worth considering as an objection to the ordeal of the palate. The practised judge will not allow one of his fingers to touch the berries; he will carefully raise the bunch by the stalk, and remove a berry from beneath, and if the bunch is of a size to justify its being shown, the depreciation of its value and beauty thereby will be infinitesimal in quantity. But as some persons attach importance to infinitesimal quantities, there is a possible way out of the difficulty. Let the gardener cut his bunch or bunches, and fix them as intended for exhibition. Let him cut from the same vine a small bunch or a small shoulder, and stage this with his bunch or bunches expressly for the use of the judges. We commend this proposal to all exhibitors and judges of grapes. There may be found perhaps two objections to its adoption. The berries in a small bunch will sometimes have a better flavour than those in a large bunch, and it may occur that an exhibitor, knowing his large bunches to be deficient of flavour, may cut a little bunch for tasting from another vine. But these objections do not appear to us to be very weighty, for we must take the exhibitor's word for the *bona-fides* in this case, as we do in every other; and the berries put up for tasting must agree in size, colour, and style of finish with the bunches, or the judges will question if they are from the same vine, and proceed at once to remove berries from the bunches. We propose, therefore, that *exhibition bunches should be accompanied with berries for tasting*; a portion of a bunch from the same vine will, of course, be all that is required.

We now have to consider that the awards of judges at exhibitions should be, as far as possible, of an intelligible nature. If the reason for an award is apparent to every spectator, it is a great advantage; but that cannot be, because every spectator does not possess knowledge sufficient to appreciate the judgments. Well, we cannot initiate the visitors to a horticultural exhibition in all the mysteries of the art, but in respect of grapes something in that way might be done, which would at least be useful to cultivators, and would prevent many a storm of indignation in reference to the decisions of judges. It might be done in this way: The card appended to an exhibition of grapes should give not only the name of the exhibitor, and specify the class in which the grapes are shown, but also the several points allowed by the judges for size, colour, and flavour. In other words, the announcements of the awards should be accompanied by a few particulars, showing the grounds on which they have been made; then, if the first prize goes to a bunch of red Black Hamburgs, and the third prize to a bunch of black Black Hamburgs, the public will know that the red samples are better flavoured than the black ones; and if the judgment is not acquiesced in, it will at least be removed from the domain of mystery.

We come at last to the final application of the principles we have thus far enunciated. It is not so desirable that bunches should be large, or that berries should be large, but it is desirable that the berries should be intensely coloured, and with a heavy bloom; or in other words, that they should have as much colour as is possible for good samples of every particular variety shown. It is also desirable that they should be well flavoured, for young vines that have been grown rank and fast will give handsome bunches and berries deficient of flavour. We propose, then, to distribute the several qualities, in their relationships to the standard of perfection, in three groups of

five each, thus: Colour and Bloom, 5; Flavour, 5; Size of Bunch, 2; Form of Bunch, 1; Size of Berry, 2; Total, 15. Let us now apply this rule to a hypothetical case.

ALL ENGLAND HORTICULTURAL SOCIETY.
CENTENARY EXHIBITION.

CLASS 100.

BEST SINGLE BUNCH OF BLACK HAMBURGH GRAPES.

FIRST PRIZE.

Awarded to Mr. Pampinator (Weight, 4 lbs. 6 oz.).

Colour and Bloom	4
Flavour	5
Size of Bunch	1
Shape of Bunch	1
Size of Berry	1
Total	12

ALL ENGLAND HORTICULTURAL SOCIETY.
CENTENARY EXHIBITION.

CLASS 100.

BEST SINGLE BUNCH OF BLACK HAMBURGH GRAPES.

SECOND PRIZE.

Awarded to Mr. Vitisator (Weight, 3 lbs. 10 oz.).

Colour and Bloom	4
Flavour	2½
Size of Bunch	1
Shape of Bunch	1
Size of Berry	2
Total	10

ALL ENGLAND HORTICULTURAL SOCIETY.
CENTENARY EXHIBITION.

CLASS 100.

BEST SINGLE BUNCH OF BLACK HAMBURGH GRAPES.

THIRD PRIZE.

Awarded to Mr. Vindemiator (Weight, 6 lbs.).

Colour and Bloom	2
Flavour	2
Size of Bunch	2
Shape of Bunch	1
Size of Berry	1
Total	8

Lastly, we must declare our conviction^s that judges should not be severely bound by codes or rules. Diversity of opinion and taste are advantageous; the chief qualifications required in a judge are ability, experience, and honesty. The ablest men will make mistakes, as may be seen at every exhibition; but there is only one safe mode of procedure, and that is to secure men known to be competent, and in whom exhibitors have confidence, and then leave them as large a margin of freedom as possible. Holding such views, we do not urge the adoption of our code as final and unalterable, we offer it simply and solely in aid of the settlement of a much vexed question, of far too important a nature to be set aside, or disposed of carelessly.

SIGNS OF A HARD WINTER.—Every year about this time the newspapers teem with paragraphs bearing some such heading as we have attached to this. Somebody finds a good crop of berries on his holly or hawthorn-tree, and at once sees therein a presage of a dreadful winter. Another observes that an elder-tree has acquired a deeper tint of red than usual, and he knows thereby that on the 10th of January all the rivers will be covered with three feet depth of ice, and blocks of brandy will be retailed in the taverns by a process of chopping fragments from frozen puncheons. Here is a sample of the prevailing weakness. A correspondent of the *Hants Advertiser*, who dates from Shirley, about two miles from Southampton, states that "he noticed the congregating of swallows the third week in August last, as if preparing to migrate, and now not one is seen. He attributes their early departure either to symptoms of an early winter or to the rain-floods, which must almost have drowned them wherever they roosted. He says that there are a few martins remaining. He heard a nettle-creep and saw a nightingale on the 12th, but he has not heard the blackbird and thrush since the 24th of June; whitethroats have been more numerous than usual this summer, and robins are now in full song and very plentiful. Birds of passage are said to have begun their annual migration southwards through Belgium a month earlier this year than usual. Already long lines of storks have taken flight. Bustards have been killed in the neighbourhood of Paris, and wild ducks have passed in such numbers that the eye cannot follow them. This is a presage of a hard winter." This correspondent at Shirley, who illuminates our Hampshire contemporary with a sage presage of a hard winter, is evidently not sage enough to know that birds are governed in their actions by what they feel in the present, and not by what they know of the future. This attribution of prophetic wisdom to animals is as absurd, if not so nasty, as the old priestly process of divining events from the entrails of animals killed for the purpose, or, as sometimes happened, disembowelled without being killed, that the priest might have the entrails extra fresh. There was a migration of birds from northern towards southern parts of Europe a fortnight ago. No wonder, for just at that time there came from

the north pole (or some other objectionable place thereabouts) a wave of cold air which pervaded Europe, and made man and beast equally afraid that winter had already come. When the temperature falls suddenly and greatly over a large tract of country, birds, having such perfect command of all climates, invariably make some migrations more or less extensive because they feel uncomfortable, but we do not learn thereby that they know anything of what is to happen six months hence. But the prediction of a hard winter from the appearance of trees is still more ridiculous, and should be expected only from philosophers in the last stage of drivelling and softening of the brain. A holly-tree knows it will be very cold in February, 1868, and so in May, 1867, it forms an extra crop of berries! Sensible doctrine that, to be sure, and very creditable to the free and independent press that gives it currency. We poor darkened horticulturists attribute good crops of fruits, whether holly-berries or grapes or apples, in great part to the temperature and other influences the trees *have been* subjected to, and would be inclined to attribute a large crop of holly-berries in 1867 to a good growth and perfect ripening of the wood in 1866; certainly not to the foresight of the tree in reference to the events of 1868. As to the movements of swallows, we saw millions on the 1st of this month—that is to say, on Tuesday last—near the village of Walthamstow, in Essex. Perhaps those were the flocks that the Hampshire sage saw congregating in the third week of August last, and which, having anticipated a hard winter, went away, but since then have adopted the opinion that the winter will be a mild one, and so have quietly returned. "Wild ducks have passed in such numbers that the eye cannot follow them." How wonderful, to be sure! Had we not better fly to the tropics to escape the death by frigidity next winter which is thus predicated? We believe we are indubbed to our usually sober contemporary, *The Farmer*, for this bit about the wild ducks. If the "Farmer's" eye could not follow them, how intensely intense must be the cold in store for us! Dreadful consideration—"the eye cannot follow them"! Then let every wise man lay in an extra store of seals.

A CALIFORNIA CUCUMBER, raised in Rock Island county (Ill.), measures three feet two inches in length, and one foot one inch in circumference at the butt.

ONION FAIRS.—At the Chertsey Great Onion Fair, well-grown sound-harvested onions sold at 3s. to 4s. per bushel. There is an abundance of grass-feed in this part of the country, and an unusually large number of stacks of second-cut hay are up. At the Wallsall Onion Fair, there was a good supply at 7d. to 9d. per reeve, or 7d. to 8d. per peck loose.

DEATH OF MR. WILLIAM WALLACE FYFE.—Mr. Fyfe, the editor of the *Nottingham Daily Guardian*, and for many years previously editor of the *Dorset County Chronicle*, died at his residence in Hounds-gate, Nottingham, on Wednesday evening last. He was a man of considerable literary ability, and well known for his labours in scientific agriculture. The deceased gentleman was the eldest son of Mr. Peter Fyfe, R.N., of Dundee, and was fifty-one years of age.

SUCCESSFUL INTRODUCTION OF THE SKYLARK IN AUSTRALIA.—At a recent meeting of the Acclimatization Society of New South Wales, it was stated that the skylarks introduced from England have bred freely, and that numbers are now to be seen in the fields in some parts of the colony. At the same meeting Dr. Bennett stated that Lieutenant Marchetti, of H.I.M. ship *Magenta*, had presented to the society two Manchourian pheasants from the north of Pekin—the species known as Swinhoe's eared pheasant (*Crossoptilon Manchouricum*), the "Ho-ky" of the Chinese—and it is the first time that this fine kind of pheasant has been introduced into Australia. Three birds arrived alive at Sydney, but one unfortunately died on board.

CAMBRIDGE HORTICULTURAL SOCIETY.

The concluding exhibition for the season of this society took place in the Corn Exchange, Cambridge. There was a good display of dahlias, gladioli, and other cut flowers, with an abundance of fruits of admirable quality. The arrangements comprised a well-filled central table for fruits, with banks of flowers and plants all round. On the table were several beautiful plants of variegated Japanese maize, contributed by Mr. Chater, of the Gonville Nursery, which made an attractive feature. One of the best filled classes was that for twelve plants in bloom, in which the prizes were divided between Mr. Chater and Messrs. Hudson, both nurserymen of Cambridge. In the class for single plants, the exhibitors were Messrs. Chater, F. Butler, and E. Smith. Several fine examples of liliuns, heaths, fuchsias, and geraniums were shown in these two classes; one of the best specimens was a *Brugmansia*, finely grown and flowered, from Mr. Chater. In the class for six zonal geraniums, Mr. F. Butler stood first with splendid round-headed and very flowery bushes of *Roi d'Italie*, *Beauté du Suresne*, *Adonis*, *Rose Rendatler*, *Clipper*, and *Amelina Grisan*. Mr. Chater, second, with *Roi d'Italie*, *Etendard des Rouges*, a second-rate scarlet; *Madame Vaucher*, *Monsieur Barré*, very fine; *Adonis*, *Marion*, a seedling of Chater's, soft rose pink, neater in habit than *Beauté du Suresne*. Third, Messrs. Hudson, with *Adonis*, *Prince of Hesse*, a nice salmon-flesh variety; *Madame Rendatler*, fine; *Souvenir de 8 Juin*, *Rose Rendatler*, and *Madame Lefebvre*. In the class for three zonals, a pretty group from Mr. F. Butler first.

Dahlias took the lead amongst cut flowers, and there were some truly fine stands. The awards were, in the class for twenty-four, first, Mr. W. Chater, of Saffron Walden; second, Messrs. Wood and Ingram; third, Mr. John Fryer, of Chatteris. In the class for twelve, first, Mr. Fryer; second, Mr. T. Webb, junr.; third, Mr. Petfield. The last-named exhibitor put up a splendid stand of twenty-four dahlias, which through some accident or error obtained no place at all. There could be no doubt, as a subsequent look over the stands sufficed to prove, that Mr. Petfield was in justice a winner; but the merits of his flowers were evidently not noticed until it was too late. Such occurrences are to be regretted, but it appears to be quite impossible always to guard against them. Asters were middling, and, as a rule, reflexed flowers were alone worthy of positions; the incurved flowers were, generally speaking, worn-out and dirty. The principal exhibitors were Messrs. Chater, Petfield, Wellsford, Webb, R. Heady, W. Chater, W. C. Smith, and J. Jones. Gladioli were fine; the twelve from Mr. Richard Heady equal to any we have seen this season. Messrs. Clarke, Webb, and Cross also competed, and presented beautiful groups of flowers. Roses were poor. Messrs. Wood and Ingram, Lawrence, J. J. Chater, Qyles, Webb, Wellsford, Heady, and Fryer, sent the best, and of course amongst so many stands there were many good flowers. Considering the season, the roses were perhaps better than could have been expected. A grand display was made of cut flowers in baskets by Messrs. J. J. Chater, Messrs. Hudson, and Mr. Jones. The first-named of these three put up a gorgeous group, consisting

almost entirely of choice subjects, such as *Tacsonia Van Volxemi*, *Lilium auratum*, *Stephanotis floribunda*, &c. The hardy flowers were scarcely good; the best baskets of these came from Messrs. Jones and Hudson; *Marigolds*, *Zinnias*, and some other less important flowers, were shown in tolerable plenty.

The best basket of fruit came from Mr. F. Butler; it contained a pine, some fine grapes, peaches, plums, nectarines, oranges, &c. Mr. Richard Heady had second place with a beautiful basket containing some fine Muscat and *Hamburgh* grapes, ripe *Noblesse* peaches, plums, &c. Some fine grapes were shown, comprising *Black Hamburghs*, *Muscat of Alexandria*, *Muscat of Lunel*, *Muscat Hamburghs*, &c. The principal exhibitors were Mr. W. Hurrell, Mr. Richard Heady, Mr. F. Butler, and Mrs. Finch. Pines from Mr. F. Butler and Mr. Heady were fine. Melons were not good in any case, though plentiful; the principal exhibitors were Mr. Finch, Mr. Webb, and Mr. Fisher. Here, as usual, the green-fleshed varieties were highest in the scale. The best twelve peaches came from Messrs. Hudson; they were fine samples of *Walburton* Admirable in perfect condition of ripeness; second, Mr. Hurrell; third, Mr. W. C. Smith. In the classes for sixes and threes, the exhibitors were Messrs. Fisher, Hurrell, Heady, *Wilderspin*, and *Clarke*. Nectarines were also fine; Messrs. Hudson's *Flrugo* grand for size, colour, and flavour; other good dishes came from Mr. F. Butler, Mr. W. Hurrell. Plums were fine; Mr. J. J. Chater first in the class for purple, with a fine dish of *Kirke's*, and again first in the class for yellow, with *Magnum bonum*; Mr. Lawrence second in both classes. *Greengages* from Mr. J. J. Chater and Mr. Lawrence, fine. *Table pears* were plentiful and fine, especially the examples of *Bon Chrétien*, *Bergamot*, and *Dunmore*. The principal exhibitors were Messrs. Barrett, Basham, Chater, Heady. Apples were shown by Messrs. *Wilderspin*, Chater, Giddins, Barrett, and Fisher. Some good samples of celery, salads, onions, and miscellaneous subjects.

THE PEOPLE'S GARDEN, PHOENIX PARK, DUBLIN.

Throwing open the Botanic Gardens, at Glasnevin, to the working man on those days when relaxation from his weekly toil enables him to enjoy their beauties was a great boon; a boon largely appreciated, and never, we believe, abused. Allocating a considerable portion of our noble park for the purpose of "The People's Garden" is another step in the right direction, and for which we feel largely indebted to those who initiated it. We have been to "The People's Garden" on two or three occasions this season, and it was most gratifying on each to witness the interest taken in them by the working classes, and the large amount of pleasure they seemed to derive from the examples of gardening, as a decorative art, which the grounds afford.

As many of our country readers may not have seen, and some may not even be aware there is such a thing at all, we purpose saying a few words to-day on the subject of "The People's Garden" in the Phoenix Park. The portion of the park set apart for it is well selected, being conveniently and advantageously situated, and well adapted for the purpose. It comprises an area of about twenty-five acres, and takes in that portion of the park from the right of the principal entrance from Parkgate Street to the road leading to the Zoological Gardens, and the entrance from the North Circular Road; the wall and grounds of the Royal Infirmary forming the other boundary. Its shape is thus somewhat triangular. It is divided by a dell, which forms a basin for the small lake or sheet of water, communication between both sides being available by means of a small bridge that spans the water where it is narrow.

The larger portion, that between the main road of the Park and the sheet of water, is what may be called the dressed ground, and comprises a large expanse of verdant turf, a considerable share of shrubbery, intermixed with flowering plants, not a little "bedding out," a frame ground for striking and growing geraniums and other bedding stuff, and a low span-roof house for wintering it. This house is about fifty feet long, and is heated by a small boiler and a four-inch pipe flow and return. A very handsome and substantial Swiss cottage is being erected beside the frame ground for the manager, Mr. M'Hugh, who has contrived, even during the present year, with his resources scarcely yet available, not only to have his grounds in beautiful condition, but wonderfully gay. During the early spring and summer months there was quite a display of spring bulbs and early-flowering annuals. Since June their place has been taken and well and gaily filled by bedding plants, the arrangement of which we shall briefly notice. The bedding runs parallel to, and only a short distance inside, the railing that separates the people's garden from the main road of the Park, and is continued by that which cuts it off from the road which leads to the Zoological Gardens, with the addition of some very large irregular beds on the slope that declines to the water's edge. The first bed of those next the main road is a large oblong. It is arranged thus: next the grass a row of blue *Lobelia*, then a belt of variegated *Alyssum*, a double row of zonal *Geraniums*, then one of *Perilla*, then a row of *Golden Chain*, a double row of *Tom Thumb Geraniums*, and a row of variegated *Geranium* down the centre. The *Perilla* is misplaced here, as it grows too high, and shuts from view the row of *Golden Chain* inside it. A large circular bed succeeds. The centre a mass of yellow *Calceolaria*, encircled by a ring of white flowered zonals, then one of scarlet do., succeeded by one of white and another of scarlet, then one of mixed single *Petunias*, and next them the pretty, and in its place most useful, *Tagetes signata*, all finished with a belt of blue *Lobelia*. They and the *Petunias* have grown quite out of proportion, and spoil what would otherwise be an effective bed. This is succeeded by another oblong bed, corresponding in size with the first, but more effective in arrangement. The centre row is yellow *Calceolaria*, then *Tagetes* with scarlet *Geranium* on either side, and these framed in with *Perilla*, then a row each of *Madame Vaucher* and *Christine Geraniums*, the variegated *Alyssum* and blue *Lobelia* being the finish. The bedding is here interrupted by a group of *Hollies*, *Arbutus*, &c., dotted over the grass. After which we meet with a large and effective bed, in botanical language somewhat cordato-lanceolate in shape, planted in patch-work fashion, with various coloured geraniums, &c., and belted with blue *Lobelia*. Then we have a very large quatrefoil bed, and one of the most striking of the whole. The centre is composed of white zonal and scarlet *Geraniums*, with a band of *Christine* running from it to the points of the four indented portions of the figure, the foliations being filled with *Gazania splendens*, about the finest surfaces of it we have seen, the whole edged with a broad border of variegated *Mint*. There appeared to be a little weakness about the centre. We would rather have the white-flowered zonal away; it is washy-looking. With the centre better this would be a most telling bed. To this succeeds a large bed of single *Stocks*, bordered with *Petunia*. The *Stock* is run to seed now, and the whole an ugly affair. This brings us to the shrubbery and flower border next the road leading to the Zoological

Gardens. In front of this border there is a raised cinquefoil bed, flanked on either side with oblong pointed beds of dwarf Asters. The centre bed is filled thus: in the centre, dark *Calceolaria*, circled with yellow do; running from this to the indentations of the figure are fine rows of *Perilla*; two of the foliations are filled with scarlet zonals, two, if we remember rightly, with pink, and one with white do.; the whole finished with a broad belt of *Lobelia*. On the slope descending to the water are two or three large beds, one of them filled with young plants of *C. toneaster*, and the other with various small shrubs. These were, about this time last year, sown over their entire surfaces, the one with *Saponaria* and the other with *Nemophila*, both forming very striking and effective sheets of floral beauty during the present year. When at the Garden last week, these beds were in course of preparation for again sowing them with these beautiful and effective annuals. Mr. M'Ingh, with four assistants, keeps the whole in very nice order. The views from the grounds are very fine; but to our mind the most charming of any is to see hundreds of the children of toil, who, but for this boon, would have been strangers to gardening effects, gazing upon them with mingled pleasure and astonishment. We have no doubt but the people's garden will be a powerful agent in creating and promoting a taste for gardening and its pure enjoyments among all classes, and otherwise, physically and morally, of the greatest benefit to the humbler denizens of our metropolis. We can well fancy what genuine pleasure our friend, Mr. Wilkie, must feel as he gazes now and then on the daily and Sunday throngs of happy faces that crowd the spot his truly kind heart and benevolent disposition took delight in beautifying for them.—*Irish Farmer's Gazette*.

ON THE GROWTH OF TROPÆOLUMS AND YELLOW CALCEOLARIAS AS BEDDING PLANTS.

A few collected ideas relating to bedding plants may perhaps aid the efforts of our horticultural friends to improve in the forthcoming year their out-door displays of colour. The beauty of the flower garden for the present season has not yet faded so far as to prevent us from noting defects or otherwise in our past arrangement. So, if we have not previously embraced the opportunity, the doing so at the present time will enable us to complete our intended plans for the future. Our first note will be to briefly consider the influence soil and situation have in the production of flowers and growth of plants when bedded out. Within the last week I had an occasion to visit a very extensive flower garden belonging to a private establishment. In the course of my survey, I came upon two beds of dwarf *Nasturtiums*, or, to speak more correctly, *Tropæolum compactum coccinea*. They were planted in a direct line within a few yards of each other, and although they were so closely allied, yet the effects from surrounding influences on their position was decidedly unfavourable to the one as compared with the other. The marked difference was that bed No. 1 had abundance of flower with moderate growth, while bed No. 2 produced very luxuriant but weak growth, with very little bloom. So opposite in character were they, that I had some doubts as to whether they were one and the same variety, till my friend the gardener assured me that they were indeed the same. To what cause are we to attribute the defective flowering of one bed as compared with the other? Bed No. 1 was fully exposed to the benefits of the solar rays during the whole of the day, while bed No. 2 was partially screened from those advantages by trees. Here was a lesson to be derived—never to be too hasty in your judgment to condemn the flowering qualities of any plants that you may have bedded out without first taking into consideration the influence of surrounding objects and circumstances on vegetation. It is not uncommon to hear that a gentleman has said to his gardener, "My neighbour So and so has a certain bed of plants (naming them), and that in perfection, while our bed cuts but a miserable figure in comparison." The gardener to some extent is then blamed for the difference, whereas, on inquiry, it would be found in ninety-nine cases out of one hundred, that it was situation, and that alone, that either retarded or promoted the blooming qualities of the plants. Having thus alluded to the *Tropæolum*, we would say something respecting its treatment, with the view of checking undue luxuriant growth, and the obtaining of plenty of blooms. This species of plants more particularly demands our attention, because as bedders they are tractable, showy, and require but little care; and in the next place the number of new varieties that are being annually introduced somewhat confuses the cultivator in his selection, as there is a degree of sameness among many of them in their colour as well as habits; in fact, you can hardly judge of their relative merits by single plants, it is only as you see them cultivated in groups or lines that you can decide as to their respective fitness for flower-garden decoration. The great value of the varieties raised by Mr. George, of Stamford Hill, is their compactness of habit; nor must we underrate the additional advantage of their preserving a healthy foliage till the close of their blooming season, while some of our older bedding varieties, whose growth is more loose and straggling, too often show a disposition to yield decayed foliage long before the flowering season has terminated.

The best means of obtaining abundance of flower with moderate growth, is never to plant them in light rich soil, nor to give them too much water at their roots during their growing season, and in whatever spot of the garden you may plant them, make choice of that which is fully exposed to the sun's influence.

The yellow *Calceolarias* and their varieties next claim our attention. Within the past few years the *Calceolaria* as a bedding plant has been very uncertain as to its existence. After they have been planted out in their beds, many have been the blanks created here and there in the beds, owing to their sudden death just at a period when we anticipated a mass of bloom. The consequence has been that numbers have despaired of ever succeeding with them again; this has led to several kinds of plants being recommended as substitutes for them. Now, to be candid, I must say that not a plant that I have seen adopted has even approached, much more equalled, the *Calceolaria* for brilliancy and constant effect, independently of its use for cutting from for bouquets. The first plant that I remember to be recommended was *Gazania splendens*. This makes a very brilliant bed during the day, yet it is a blank towards evening, owing to the flower closing when the sun goes down.

The pretty *Marigold*, *Tugetes signata pumila*, has been highly lauded in the seed catalogues as being every way on a par with the *Calceolaria* for effect; but its flowers are perfectly insignificant in comparison, and, besides, the odour of the foliage is anything but pleasant, so that it is not adapted for bouquets. As the season has now arrived for commencing the propagation of the *Calceolaria* in earnest, a few words on the best method to be adopted may be acceptable. Our object must be to check the almost universal evil complained of, and thus go on increasing instead of lessening their number for next year.

I will, then, just simply describe my practice and success this year, without any preface beyond stating that the means adopted by me have been repeatedly advised in these columns by our worthy Editor. Before planting out, the plants should be subject to repeated fumigation of tobacco, so that not a green-fly is allowed to nestle among them. Having then arranged my plants in their pots on the beds at the respective distances I required previous to planting, I have placed beside me a box-barrow full of good decayed manure; then with a small spade, about six inches in width, I make the holes, filling up the same with the rotten manure; into this the plants are inserted, and as a proof of the value of the practice, I will refer to two beds of *Aurea floribunda*, containing nearly a hundred plants each, which were planted by me in the spring of this year. Not one plant has failed, and for abundance of flower and general health they have been the admiration of all who have seen them. Not a red-spider has fixed its abode among the foliage, an insect to which this variety is very subject in very dry and hot weather. In whatever part of the garden they are planted, there the manure has been used with equal success, excepting to *Calceolaria amplexicaulis*, which does not require it, as it is seldom a plant of this beautiful variety fails. I really cannot understand why it is not more generally cultivated. I have two large beds of it in flower at the present time, surrounded by the dwarf blue *Ageratum*, and the effect is brilliant in the extreme. For cut flowers, on account of the length of their stalks, they are invaluable.

JNO. F. McELROY.

THE NEW HARDY CLEMATISES.

We have long known, and ere this spoken, of the great merit of some new hybrids and varieties of *Clematis* recently raised, but we had no sufficient idea of their capabilities till we visited the nurseries of the raisers, Messrs. Jackman, of Woking, in the early part of this month. The *Clematis* is a well-known genus, often very pretty, from exhibiting a multitude of small flowers, like *C. campaniflora*; often showy, from a profusion of handsome ones, like *C. montana*; and frequently rampant, like the common Traveller's Joy; but it is only of late that it has become magnificent, or rather that its magnificence has been rendered available for flower-garden ornamentation and general use. There has long been a splendid species of *Clematis* (*lanuginosa*) in cultivation, with flowers of noble proportions, often six, seven, and eight inches in diameter. This, though finer as regards its size than any of the new ones, and having in addition to the normal blue form two exquisite snowy white varieties, was generally so slow to produce flowers, and leaves too, that it remained almost an unused plant. Hardy enough to do some good in nice positions, it was almost useless for general open-air culture. But, fortunately, Mr. Jackman succeeded in crossing a very hardy free-growing species with this *lanuginosa*, and the result is a breed with the vigour of a common *Clematis* and the large and splendid flowers of the *lanuginosa*. But the colour was also changed: rich purplish and plum hues were imparted to the pale lavender-blue or white of *lanuginosa*, and some of the richest hues of purple to be found in any flowers are now displayed by the varieties of this race, while one or two of the new kinds are of a fine soft blue or mauve, with stiff petals and handsome form. Not only are they distinguished by immense size and the richest colour, but their profusion of bloom is something quite remarkable. Imagine a mass of foliage five feet high, supported on stakes, bearing flowers nearly as large as tea-saucers, and so profuse that their leaves are quite obscured. We have seen the plants shown in pots and in a cut state, but had no idea of their profuse way of blooming, and consequently of their great value, till we saw them at home, growing in various positions in the open air, and flourishing there as freely as British weeds could do. They were arranged in various positions—planted in beds and pegged low down, like verbenas or ordinary bedding plants, or supported on stakes, up which they grew to a height of five feet or thereabouts, and then fell down in wreaths of the richest purple. However, few can have an idea of their beauty till they see them well grown. We believe them to be the noblest hardy hybrids that have been introduced for many years, and likely to effect much for the flower-garden, pleasure-ground, or rockwork. Being perfectly hardy, they are, of course, a great help in saving us from the perpetual expense for protection so much needed now. In fact, so satisfactory are they, that the only thing we have to settle about them is their position, and how they may be used most gracefully. Firstly, they will be of the highest value as purple bedding plants—our present colours in this way being poor indeed compared to these. They may be used effectively at about the same height, or a little higher, than the verberna; and near the earth, well pegged down in this way, they are less exposed to danger from storms, and enjoy a greater degree of heat. Eventually a beautiful harmony may be presented by beds planted with them, if the various shades of purple, plum-colour, &c., are associated in lines or circles; but it is needless to attempt the enumeration of the many ways in which they will be found effective and beautiful when associated with other good things. To pass from their use as bedding plants, we have next to consider them as the noblest obtainable ornaments for low walls, trellises, &c. To such they must, of course, be nailed or tied; and, once firmly fixed, if allowed to fall down in rich masses so much the better. We, however, consider that the most simple and grand use of all to make of them would be to plant them on large rockwork, giving them a good depth of rich, light, and sandy earth, and allowing their shoots to fall over the face of the larger rocks without training, pruning, or any other attention whatever. Of course, almost the same words will apply to rustic banks, &c., with a warm exposure. For drooping over the margin of those raised beds with edgings of wood or stones, they will look superb.

As to soil, it is important to note that they do best of all in a very sandy light one. They will not refuse to grow freely in any good soil, not too stiff; but we have always observed them do famously in very sandy loam, and in any case in light stuff—deep as you like, however. Mulching the ground—or, in other words, covering it with an inch or two of loose, half-rotten manure during the summer—they like very much. It keeps the ground open and agreeably moist to the very surface. As to pruning, it is simply managed by cutting the plants back to within four or five inches of the ground in early spring—that is, if they are used for bedding, or in any way in which they may spread out low upon the ground. But when we wish to cover walls, &c., with them, the case is altered, and the stems may be allowed to go as high as they like, merely cutting them back and thinning them out a little. In banks, rockwork, &c., they might with advantage be left "to nature," no pruning, no attention being required after the first planting in good free soil. The best of the class of Clematisses of which we speak, and it must not be confounded with any others, are *C. Jackmanni* and *rubro-violacea*. Both these kinds are now cheap. But since their appearance many new kinds have been raised, of which the best are *rubella*, Prince of Wales, Lady Bovil, Thomas Moore, and Mrs. Bateman.—*The Field*.

CONCERNING FRENCH RAISERS OF ROSES.

A few facts about raisers of our pot flower may be useful just at this time, when our neighbours on the other side of the Channel are furbishing up their most florid adjectives for descriptions of their—for the most part—so-called new roses. These descriptions, in which the elegant tints of the rose are variously compared to the aurora, to jasper, to tender flesh, &c., &c., are snares and gins to the unwary; for as Mr. Cranston, and our Editor, and other practical rosarians have most truly urged, not one in five of our French friends' new roses are worth propagating.

Perhaps even Horatius Flaccus, that ancient intimate of our Editor, was himself taken in some 1,900 years ago by a wily Asiatic catalogue maker. Listen to him—

*Persicos odi, puer, apparatus,
Mitte sectari, rosa quo locorum
Sera moretur.*

Carm. xxxviii. lib. i.

Translated,

These gorgeous worded catalogues I hate;
These Persian roses will not vegetate:
You rascal, cut your stick—no! wait!—
Cut me a really good rose that blooms late.

As therefore the sublimity of description of new roses is no adequate test of the rose's worth, we must find some other test. Probably the best test is the results of past years, as compared with the promises in the catalogues. Hence it will be found, after much trouble and painful analysis by the anxious inquirer, that there is just one Frenchman out of twenty-four, or thereabout, from whom we may confidently expect good new roses. Let his name be printed in large and lovely type—

Monsieur Lacharme.

This gentleman is quite the senior wrangler in rose raising.

Next to him in order of priority come Guillot (*père*), Jamain (sends out very few and very good), Guillot (*filis*), Marest, Granger, Charles Verdier, Levêque, Portemer, and Pernet. I should like to have included Eugène Verdier and Margottin; but I fear that the latter lives too much on the fame of Jules Margottin, and the former occupies so anomalous a position that he ought to be made sensible of it. His custom is to send out yearly some eight or nine so-called varieties, of which at the most three or four are good, and occasionally extra good, while the rest are bad, really too bad. And yet this raiser is a most thorough rosarian, and well knows the worth of such roses as satisfy the mind of us simple English folk, whose very nature it is to be taken in by such enticing catalogues as his. Now, will he be satisfied with a reasonable offer. It is this: If he will yearly send out only such roses as he knows are good, without that unhappy *addendum* of hollow-eyed unsubstantial ghosts of roses, I will undertake to place him in this list next to M. Guillot (*père*), and reform my opinion.

Next to M. Eugène Verdier, as he now stands at the bottom of my list, come the *profanum vulgus* of rose-growers, perfect pyrotechnical artists in catalogue making; but taking the test-percentage of their productions, I find that not more than one-tenth, taken collectively, is good enough to be retained in the lists. These stand as follows in order of merit: Liabaud, Gonod, Fontaine, Ducher, Oger, Damaizin, Gautreau, Touvais, Trouillard (foreman of Leroy d'Angers), Moreau et Robert, and Souppert et Notting.

Besides all the foregoing, there are Lecompte, Baumann, and Cechet, of whom I know nothing beyond this, that they have respectively raised *Maréchal Vaillant*, *Marie Baumann*, and *Comtesse de Jaucourt*, very first-class roses; so that if I hear that they are at all likely to send out other roses, I should like to try them.

VIATOR.

THE BEECH.—The beech (*Fagus sylvatica*), if it be not the most magnificent of all British trees, certainly rivals the oak itself in size and majestic beauty; a grove of stately well-grown beeches on chalky loam is at once graceful and grand; the effect on the spectator is thoroughly awe-inspiring; the massive, smooth, upright fasciculated trunks, and the far-spreading groin-like branches call to mind some huge cathedral nave; the trunks are pier-like, massive, bossed, and chamelled; the branches like arches interlacing, curving, and entangling; and the roots, moulded, curved, grotesque, and snaky, help to complete a scene of the most impressive character. The body of the tree is frequently stained of a vivid grass-green, produced by the growth of a parasitic lichen, the beauty of which is enhanced on a summer's day by the bands of pure gold projected on the limbs where the struggling sunbeams find a temporary passage through the dense umbrage above. The value of the wood for building purposes is by no means equal to the beauty of the tree; for whether in a living state and full of sap, felled for use, or dried and made up into furniture, beech-wood is invariably riddled by a parasitic worm; this is one of the principal reasons why the wood is seldom or never used for floors and roofs.—*Builder.*

REPORT ON TRIAL CULTURE OF LETTUCES AT STOKE NEWINGTON, 1867.

Having determined to investigate a few points of some interest in respect of the distinctions of character amongst certain varieties of lettuces, I applied to Messrs. Barr and Sugden in the early part of the present year to supply me with the purest possible samples of seeds of the kinds intended to be grown for comparison. Messrs. Barr and Sugden kindly engaged to obtain pure samples of the kinds required, and while so engaged secured for me several other kinds; so that in the end, instead of receiving seeds of about a score varieties, they sent a collection of no less than eighty! Considering that a large proportion of these must be nearly alike or absolutely identical, and finding increasing interest in the subject, a selection was ultimately made of sixty-five sorts, and these were sown for summer culture, the remaining fifteen varieties being set aside for autumn sowing, to test their several values as winter lettuces. The cold wet spring of 1867 was peculiarly unfavourable to an enterprise of this kind, and, therefore, after waiting some time for suitable weather for sowing the seeds in the open ground, it was found necessary to sow them under glass. One of the borders of the Paxtonian house in the experimental garden, on which mushrooms had been grown during winter, was covered with a few inches of fresh friable loam, and on the 15th of April the seeds were sown in drills across the bed very close together. In the mean time a bed in the trial-ground was prepared by deep digging and liberal manuring, both with good stable-manure and a top-dressing of wood-ashes. As soon as large enough, the whole collection was planted out in rows averaging a foot apart, but a breadth of two feet was allowed between the rows of the strongest-growing varieties, such as Bath Cos, and less than one foot between some of the diminutive kinds. One row each of all the varieties was thus secured in a bed sixty-six feet long, and the growth from first to last was perfectly satisfactory, in fact, a finer lot of lettuces had never been seen in the district before even by the "oldest inhabitant." None of the samples were tied, and only a few were bleached by other methods. The rule followed was to thin them out as much as needful to allow of perfect development, but otherwise to leave them to grow in their own way, to allow of a fair study of their several characters. I made an inspection every three or four days from the time they were growing freely until they were in great part run to seed, and the following notes are transcribed from the book in which the entries of observations were made from time to time.

Lettuces may be primarily divided into two classes:—1. CABBAGE LETTUCES. 2. COS LETTUCES. The varieties in the first section are more or less round-headed and spreading, and in flavour less sweet and succulent than the Cos varieties, though many of them are notable for a delicate nutty or buttery flavour, and all of them are good for mixed salads. The varieties in the second section are usually upright or oblong, and when well blanced, either by tying or by their naturally close growth, are generally elegant in appearance, and of a welcome, crisp, and sweetish flavour. There are some very badly-flavoured varieties to be found in this class, but as a rule they are the best lettuces to eat without dressing *pur et simple*; whereas the drier and more nutty flavoured cabbage varieties are better adapted for dressing, and especially for mixed salads. These two classes may be again subdivided in order to separate the coloured varieties from the green, and again they may be subdivided in order to present to the cultivator groups of varieties adapted for particular purposes, some being well suited by their hardness for autumn sowing; others, by their capability of enduring heat without hastening into flower, being well suited for sowing in spring to afford supplies during the hottest period of the summer. We shall endeavour to direct attention to all these several points, intending first to describe the varieties.

CABBAGE LETTUCES (seed sown April 15).

BERLIN WHITE.—A green variety; leaves very broad, wavy, and spreading; growth medium, quite compact, forming a round, rather loose heart. Fit for use June 27th, and continued good till July 20th, at which date it began to run for flower. This is a tender, mild, buttery lettuce, of first-rate quality and elegant appearance.

BATAVIAN WHITE.—A green variety of robust habit; leaves broad, wavy, curled, and wrinkled, slightly tinged with red at the edges. In growth very spreading, and covering too much ground. Ready for use July 15th, and lasting a fortnight. Tender, nutty, and agreeable. A second-rate lettuce.

BERLIN KING'S HEAD.—A green variety, of spreading habit and medium growth; the leaves slightly wavy, of a light green colour. Ready for use June 27th, and lasting ten or twelve days. This is a dry-textured, nutty lettuce, well adapted for the salad bowl, but not sufficiently succulent to make a grateful dish without dressing.

BIGOTTE.—A red variety; leaves roundish, wavy, and wrinkled, the edges of the leaves smooth; the bases of the leaves a bright green colour, the upper half bright reddish bronze, shading to rose. This is one of the handsomest of the coloured lettuces, and might be allowed a place in the flower garden. It is comparatively valueless for the table, being tough and tasteless, but it is extremely beautiful when cut through, and may occasionally be used for garnishing. Ready for use June 25th, and lasting about ten days. It differs from Blood-red Dark chiefly in a prevailing rosy tint, but otherwise is almost identical with it. A third-rate variety.

BLOOD-RED DARK.—A red variety; leaves roundish, wavy, and wrinkled; grass-green at the base, thence shading to bronze and brownish red. Ready for use July 5th, and lasting only eight or nine days. It is tough and tasteless, fit only for the bowl or for garnishing. A third-rate variety.

BATAVIAN BROWN.—A brown variety, intermediate between cabbage and Cos. Leaves large, oblong, curled and wrinkled; deeply pitted, so as to appear warty on the inner side; dull green, with tinge of brownish bronze at the edges. Growth large and loose; does not require tying; forms a large loose heart, which is juicy, mild, crisp, and slightly sweet. Ready July 6, and lasting fifteen days. A good lettuce, but covers too much ground. A second-rate variety.

BROWN GENEVA.—A brown variety. Leaves large, round, curled, and wavy; light green, with decided tinge of brownish bronze, by which chiefly it is to be distinguished from Green Cabbage, Coquille, and many others. Ready for use June 24th, and continued good till July 20th. A tender, juicy, almost tasteless lettuce, deserving to rank only as third-rate in quality.

BLOOD-RED.—A red variety. In leaf, growth, and general character, resembling Blood-red Dark and Bigotte, but darker in colour than either of them, and a neater grower. It is the best of this series, being mild, buttery, and nutty in flavour. Fit for use July 5th, and lasting good about ten days. A second-rate variety.

BRUNZUL EARLY.—A green variety. In general character closely resembling George's Early, Berlin White, Small Cutting, and Prince's Head; but the two last-named are of smaller growth. It is, however, a distinct variety, having a neat compact appearance; the leaves broad, wavy, and yellowish green. It forms a rather loose heart, which is tender, buttery and nutty. Ready June 27th, and lasting twenty days. A good second-rate variety.

COUILLE.—A spotted variety of medium size and spreading habit; the leaves curled and wavy, light green, with a few brown blotches. This

eating undressed. Ready for use July 1st, and lasting twenty days. In other parts of the ground were samples of Drumhead from Messrs. Sutton and Sons, of Reading, Messrs. James Carter and Co., of High Holborn, Messrs. Wheeler, of Gloucester, Messrs. Smith and Simons, of Glasgow, Messrs. Drummond Bros., of Edinburgh, and Messrs. Stuart and Mein, of Kelso. Minute differences of character were traceable amongst these, a proof that the stocks were from different sources; but it was not possible to detect any differences of value, they were all good and true, and none of them surpassed the sample from Messrs. Barr and Sugden. A first-rate variety, which may be obtained

GREY PARIS COS.

DRUMHEAD.

variety forms a compact heart, which is mild, buttery, nutty, and sometimes slightly bitter. Ready June 30th, and lasting ten days. A good second-rate variety.

CRISP SMALL EARLY.—A green variety like Drumhead, forming very little heart, but being nearly all eatable, even to the outside leaves. It is mild, buttery, and juicy, and is improved by being blanched; for this purpose it should be covered for a few days. Ready June 24th, and quite past in twelve days. A serviceable second-rate variety.

CRISP GERMAN.—A green variety of robust habit spreading in a round flat

in perfect condition from the beginning of June to the end of November, and even till after Christmas in extra mild seasons. This is to be accomplished by sowing early in a gentle heat, and planting out when the season is sufficiently advanced to allow of it, and continuing to sow successional rows in the open ground until the middle of July.

EARLY WHITE SPRING.—A green variety of minute growth, very much curled and wrinkled, compact, bright yellowish green. It forms a firm dense heart, which becomes perfectly blanched, is dry, bracy and almost tasteless; hence is best adapted for the bowl, and is in fact one of the best salad lettuces

TRIATOR LARGE GREEN.

SILESIA.

tuft, the leaves broad, wavy, curled, wrinkled, and pitted, bright light green; exceedingly pretty. It is one of the best kinds in the class of which Drumhead may be regarded as the type, but is more spreading in growth and more curly than Drumhead. Ready for use July 1st, and continuing good about fifteen days. It is mild, very buttery, and nutty in flavour, and may be considered in every respect first-rate.

DRUMHEAD.—A green variety; leaves broad or oval, deeply wrinkled, pale cheerful green, rather upright in growth, and forms a large loose heart, which is always crisp, sweet, succulent, and equally good for the bowl or for

known, and well adapted for frame culture. Ready June 20th, and lasting twenty days. A first-rate variety for salads, and well adapted for supplying the market early in the spring.

EARLY SIMPSON.—A green variety of the Drumhead section, most nearly resembling the crisp German. The leaves are ovate or roundish, slightly wavy and very much wrinkled, slightly notched and crisped on the edges, the colour bright yellowish green. It forms a small loose heart, which is mild, buttery, and nutty in flavour. Ready July 2nd, and lasting ten days. Second-rate.

EMPEROR'S HEAD.—A green variety of medium growth, spreading; the leaves much curled and waved; light green overspread with dull brown, changing to red at edges. Quite distinct in character; forms a compact heart, which is dry, scarcely tender, and tasteless. Worthless.

EARLY SILESIAN.—A green variety of spreading habit, forming a round flat tuft; the leaves broad, much curled, and pitted; bright light green, extremely elegant. It forms a loose heart, and the outer leaves are nearly as good as those within, so that if used at all, it is nearly all fit for use. This is a dry, tough, and almost tasteless lettuce, good for the bowl, but unfit for any other purpose. Ready July 10th, and lasting fourteen days. A third-rate variety.

ENDIVE-LEAVED (No. 1).—A green variety, very distinct and elegant; the leaves deeply lobed, waved, curled, and crisped like endive. Ready for use June 17th, but needing to be carefully blanched for a few days, after which they quickly rot. The flavour is mildly bitter, the texture rather tough. The only use possible for this variety is as an ingredient in a salad, and for that purpose there are many other varieties far better. The plants left to finish their growth formed pretty pyramids of bright green crisped leafage as elegant as ferns, and quite worthy of a place in the flower border. Except for garnishing, and to serve as a substitute for endive, this variety is of no value.

ENDIVE-LEAVED (No 2).—A green variety, differing slightly from the foregoing, but like it needing to be blanched, and then having the flavour and texture of endive. It is of a pale green colour, extremely beautiful, and might be useful in the flower border as well as for garnishing.

GEORGE'S EARLY.—The same as Small Cutting.

forms a loose heart, which is dry, buttery, and slightly nutty in flavour. Ready July 1st, and lasting ten days. A good second-rate variety, closely resembling Stonehead, Switzerland, and several others.

NEAPOLITAN.—A green variety, and the type of a most excellent class. It is of medium growth, but if required may be grown to a great size. The leaves are broad, much curled and wrinkled, and the edges frilled; colour dull grass-green. It forms a good but loose heart, which is juicy and sweet, and fit for any purpose. Ready June 27th, and lasting fifteen days. An elegant first-class lettuce, the only fault of which is that it covers rather too much ground.

NORMANDY.—A green variety of spreading habit, growing close to the ground, and covering a considerable space; the leaves are waved and wrinkled, with smooth edges, grass-green. Forms a loose heart, which is mild, buttery, and slightly nutty in flavour. Ready July 4th, and lasting about twenty days. This is an ugly and rather coarse variety, which we must class as second-rate, but in doing so we are bound to call attention to its long-lasting properties.

IMPERIAL.—A green variety and one of the oldest in cultivation. It is distinct in growth, large, spreading, the leaves very broad and roundish, pale grass-green. Forms a large loose heart, which is coarse and tasteless. Ready July 16th, and lasting twelve days. A third-rate or quite useless variety.

ROYAL WHITE SUMMER.—A green variety of medium size, and spreading habit; the leaves are roundish, deeply waved, and slightly wrinkled, pale green. Forms a loose heart which is not tender, but juicy, buttery, and nutty. Ready June 30th, and lasting twenty days. A second-rate variety

BROWN BATAVIAN.

SPINAGEE OR OAK-LEAVED.

LARG BROWN BEST.—A brown variety, differing from 'Brown Geneva only in a degree that may be accounted for by considering it a good stock of that variety.

LARGE GREEN.—A green variety, of larger growth than the Coquille, which it resembles in general character, but is coarser, and covers too much ground. It is, however, a good second-rate variety.

LARGE VERSAILLES.—A green variety, bearing a near resemblance to the Early Silesian. It is of spreading habit, the leaves much waved and wrinkled, but the edges are smooth, pale grass-green, forming a loose heart, which is mild and buttery, but almost tasteless. A second-rate variety, covering too much ground for the return it makes. Ready July 1st, and lasting good about fifteen days.

LARGE RED.—A red variety of great size; leaves broad, spreading, much wrinkled, grass-green overlaid with patches of bronzy purple; forms a large, round, solid heart, which is tender, juicy, and slightly bitter. Ready June 30th, and continuing good twenty days. This is not a handsome lettuce, and will never have many admirers in this country. But on the Continent it is much esteemed for dressed salads, and is especially valued as a market-lettuce, being adapted for hotels and restaurants, its great bulk and slightly bitter flavour being recommendations. It is good also for hot climates and dry soils. As compared, however, with other lettuces in use in this country, we must not assign it a higher place than the second class.

MALTA.—The same as Drumhead.

MOUSSERONNE.—A red leaved variety; small, coarse, the leaves reddish or bronzy, the heart small, tough, tasteless. A worthless variety.

MOGUL LARGE YELLOW.—A green variety of medium size and spreading habit, the leaves broad, curled, waved, and wrinkled, bright yellowish green;

SMALL CUTTING.—A green variety of small neat growth; the leaves are curled and slightly wrinkled, pale green. Forms a very compact solid heart, which is buttery and slightly bitter. Ready for use June 20th, and lasting at the utmost eight days. This is a good salad lettuce, and probably well adapted for market, as a large number of good solid hearts may be grown on a comparatively small extent of ground, and when in their prime they are neat and tempting in appearance; but its tendency to "bolt" is much against it, and we must not class it higher than second-rate.

SNEDESHEAD EARLY.—A spotted variety of medium growth; the leaves very broad, slightly waved and wrinkled, grass-green, with a few blotches of purplish bronze and an occasional tinge of red. Forms a large compact heart, which is mild, buttery, and agreeable, but not sweet. Ready June 27th, and continuing good twenty days. A second-rate variety.

SPOTTED RED CABBAGE.—A red variety of medium growth, and very distinct in the class of coloured cabbage lettuces. It spreads freely, covering a large extent of ground. The leaves are broad, much wrinkled, dull green overspread and suffused with reddish bronze, and sometimes richly tinged with carmine. It is the most handsome of the coloured class, and eminently attractive. Forms a small loose heart, which, when cut through, is whitish at the base and otherwise bright red, and suggesting a white-fleshed lettuce spoiled through having been dipped in blood. By some this may be considered a recommendation, but we must confess our dislike of its appearance, except when on the ground, where it is decidedly handsome. The heart is of a dry-bready texture, slightly bitter, moderately tender. Ready for use July 12th, and continuing fit for cutting about fifteen days. A third-rate variety.

STONEHEAD FRAME.—A green variety of small size, very compact

not in growth; the leaves broad, much wrinkled, pale green. Forms a pretty and somewhat compact heart, which is juicy and sweet, and fit for bowl or table. Ready June 27th, lasting fifteen days. A first-rate variety.

PAS DE CALAIS.—A green variety of medium size, spreading, pale green. Forms a loose heart, which is buttery and nutty in flavour. Ready July 10th, and soon over. A second-rate variety.

PERIGNON.—A green variety of a pale green colour, forming a round, compact, cabbage-like heart, which is buttery and bitter. Ready July 12th, and lasting fifteen days. A third-rate variety.

PRINCE'S HEAD.—A green variety of medium size; the leaves waved and curled, forming a large loose heart, which blanches perfectly without tying. It is mild, very buttery, with slight trace of bitterness. Ready for use June 27th, and lasting good about fifteen days. Second-rate.

SPOTTED WHITE CABBAGE.—A spotted variety of robust habit and spreading growth; the leaves broad and deeply wrinkled, pale green lightly speckled with rosy purple. Forms a large loose heart, which is mild and buttery, but not sweet. Ready for use June 25th, lasting twenty days. A second-rate variety.

SPOTTED LARGE WHITE CABBAGE.—A spotted variety, closely resembling the last, but differing in colour, being speckled with dull purple, and in flavour being more dry and inclined to bitterness. Ready for use June 25th, and lasting about twenty days. A second-rate variety.

TURKISH BUTTER.—A green variety of medium size, resembling the Perignon, but not identical with it; leaves broad, almost smooth, curling back, light grass-green. Forms a very cabbage-like loose heart, which is breadly and bitter. Ready for use July 1st, and lasting about twelve days. Third-rate.

SPOTTED LARGE.—A spotted variety, distinct from others in the list bearing the same or a similar name; in growth spreading, the leaves very broad, roundish, and deeply waved and wrinkled, the edges smooth, colour grass-green much covered with patches and dots of reddish brown. Forms a good rather loose heart, which on the 27th of June was in perfection, being then slightly sweet and buttery; on the 12th of July the heart was still good, but had acquired a bitter flavour; began to bolt twenty-seven days from the time the hearts were first fit for tasting. A good lettuce for hot climates, but for English gardens quite second-rate.

TRIATOR, LARGE GREEN PALE.—A green variety. Resembling in every respect the Turkish Butter lettuce, except that this is of smaller growth and a few days later. In flavour dry and nutty. Ready for use July 5th, and lasting about ten days. Third rate.

SPINAGEE OR OAK-LEAF.—A green variety, curious and distinct, the leaves being long and deeply lobed and remotely resembling the leaves of the common oak; pale green. This variety does not form a heart and appears to be utterly useless, though when shredded with other vegetables it may make a bearable ingredient in a salad. Previous to flowering it was almost ornamental. It was in flower July 15th, and then had the appearance of a worthless weed. It is the *Lactuca quercina* of the botanists, a plant altogether distinct from *L. sativa*.

STONE TENNIS BALL.—A green variety of small growth, forming a neat, round, rather spreading tuft of a cheerful light green colour. The leaves are much wrinkled. Forms a close compact heart, which blanches perfectly, and is of a tender texture, dry, breadly, and comparatively flavourless. Ready June 25th, and lasting good about twenty days. A first-rate variety.

WHITE TENNIS BALL.—Forwarder and paler colour than the Stone Tennis, being ready for use June 20th, and lasting only twelve days.

TOM THUMB.—The best strain of the Tennis-Ball section, and the best of the small, close-hearted, dry-textured cabbage lettuces. When well grown, it is an elegant vegetable, and though less palatable when eaten alone than some of the sweeter and more succulent varieties, or than the best of the Cos section, is nevertheless universally esteemed for the table, the salad bowl, and for soups; strictly speaking, however, these are salad lettuces and are especially adapted for winter culture.

SWITZERLAND.—A green variety of large growth, the leaves wavy, pale yellowish green, large loose heart of a coarse texture, watery and tasteless. Ready for use July 12th, lasting but a short time. Third-rate.

RED-EYED OR VICTORIA.—A red variety of small growth, spreading, leaves roundish, slightly waved, smooth-edged, bright grass-green with a slight rosy tinge. Forms a small loose heart; flavour nutty and agreeable. Ready June 27th, and lasting fifteen days. Second-rate.

WHITE STONE.—A green variety of medium size and spreading habit. Leaves broad, curled, waved, and wrinkled, light grass-green. Forms a loose heart, which is dry, flavourless, and somewhat coarse. Second-rate.

Cos Lettuces.

BROWN BATH.—A brown variety. This is a typical lettuce of the highest repute, serving equally well for spring and autumn sowing, and well adapted to supply lettuces throughout the year. There is no essential difference of appearance between the true White-seeded Bath and the Brown-seeded Bath, but in growth they differ, the White-seeded being quicker and less hardy than the Brown; the latter therefore is better of the two adapted for winter culture, and is less likely to bolt in the event of hot weather occurring when it is in its prime. Growth large, the leaves oblong and nearly the same width throughout, slightly wrinkled, and the edge of the leaf crisped or waved. The colour is light green overspread with a tinge of brown or purplish brown, which becomes more decided towards the edge. Forms a fine white heart without tying; is very crisp, buttery, juicy, sweet, and delicate. Ready July 19th, and lasting in perfection eight days. A first-rate variety.

MONSTROUS BROWN Cos.—A brown variety. A quick-ripening and large-growing variety of the Brown Bath. It attained the largest size of any lettuce on the ground. The leaves the same width throughout, slightly waved and wrinkled, not crisped or waved on the edges; light green overspread with purplish brown, which deepens towards the edge of the leaf. This forms a large, close, conical-shaped heart, needs no tying, is tender, sweet, crisp, and buttery; a most delicate and delicious lettuce. Ready July 12th, and lasting in perfection eight days.

FLORENCE Cos (Black-seeded).—A green variety of large growth, leaves long and narrow, distinct and handsome, uniform pale green. Forms a close heart without tying, but is better if tied for a few days. It is delicate in texture, tender, buttery, sweet, and nutty; the perfection of a lettuce for eating unpressed, and making an extremely handsome dish. Ready for use July 19th, and lasting fourteen days. It is of the Brunoy strain, and agrees with Brunoy except in some very minute particulars. A first-rate variety.

FLORENCE Cos (White-seeded).—A green variety. This does not differ in any essential from the foregoing.

GIANT GREEN.—A green variety of immense growth, belonging to the Brunoy section. Leaves nearly the same width throughout, neatly rounded at the summit, smooth and convex or shell-like, pale dull green. This turns

in well without tying, forming a large handsome heart, which is very buttery, tender, and delicate; less juicy and sweet than some other varieties. In perfection July 12th, and lasting eight days. First-rate.

GRAY PARIS Cos.—A green variety, with long rugose leaves of a light green colour on the inner side, grayish green on the outside; growth peculiarly upright and compact. The leaves of this variety are shell-shaped, and they turn in round the heart and render tying quite unnecessary. The heart is large and close, crisp, tender, and delicate. Ready July 12th, and lasting eight days. A peculiarity of this variety by which the genuineness of a sample may be tested in addition to the tests furnished by the foregoing description, will be found in the peculiar rugosity of the leaf, which, when viewed across the surface, presents an almost regular zig-zag line, thus AAAAAA

GIANT WHITE.—A green variety distinguishable from Gray Paris only as being rather more upright in growth, and the leaves less distinctly surfaced with the zig-zag rugosity. It is a strong stock of Gray Paris, but in no respect an improvement.

BRUNOY BLACK.—A green variety, the basis of the section to which belong the Florence and the Giant Green, the description of either of which will serve for this. Requires tying and forms a fine close heart. Ready July 19th. A first-rate variety.

BRUNOY WHITE.—A green variety, identical with the last, with the sole exception that it is white-seeded.

IVERY'S NONSUCH.—A green variety. A well-selected stock of the true Brunoy and the best strain of this section on the ground. If kept true to its present character, Ivery's Nonsuch may be regarded as the best known model of a Cos lettuce.

IMPROVED SPOTTED.—A spotted variety of large growth, fine habit, and extremely handsome. Leaves oval, broadest at the summit, dark green heavily spotted with black, the outer leaves sometimes richly coloured a bright reddish bronze. Hearts well without tying. Fit for use July 30th, and lasting fourteen days. The heart is not tender, and is almost flavourless, like moist tissue paper rather than the heart of a lettuce. This variety is worthless in an English garden unless it is valued for its fine appearance, but in a hotter climate it has its uses, supplying a grateful salad when little else of the kind can be obtained.

SPOTTED Cos (Black-seeded).—A spotted variety of robust habit and spreading growth, with oval leaves, which are much curled and waved; dark green heavily splashed and spotted with reddish brown and bronze; forms a good heart without tying. The heart when cut open is of a pale yellow colour heavily spotted with bright red, and decidedly elegant; never suggesting, as some of the spotted kinds do, the idea of their having been dipped in blood. Ready for use July 12th, and still good on the 1st of August. In texture coarse and tough, and invariably bitter or tasteless; therefore of no value except desired for its appearance.

SPOTTED Cos (White-seeded).—A spotted variety distinct from others bearing the same name. Growth large and spreading, the leaves broad, much wrinkled, dark green heavily patched, blotched and spotted reddish brown. Sometimes the inner leaves are wholly coloured a rich chocolate hue, and glisten as if varnished. This needs tying; it then forms a large compact heart, which is tender, buttery, nutty, and agreeable. Ready July 16th, and lasting fourteen days. Though far inferior to the green Cos varieties, this is not to be despised; and probably on hot soils, and in hot dry seasons, it would be found serviceable, when the more delicate kinds were useless, otherwise we must class it as third-rate.

MAGDALEN Cos.—A brown variety quite distinct, the leaves very narrow and smooth, pale green suffused with a brown tinge. Requires tying. Forms a rather loose heart. Ready July 20th, and lasting eight days. In texture and flavour inferior to the best varieties of Cos, but useful for its lateness, as it comes in when the best kinds are past, or nearly so. A second-rate variety.

RED Cos.—A brown variety. Very large leaves, light green at the base, remaining part bronzy brown. Forms a large close heart without tying. Ready July 27th, and lasting twenty days. In texture coarse, and in flavour neither bitter, sweet, nor nutty; the only term we can find to indicate the flavour is an indefinable soapiness. Third-rate for English gardens, but useful in hot climates and on thin hot soils. S. H.

Calendar.

WORK FOR WEEK COMMENCING OCTOBER 5.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—If the advice we have given of late years has been followed, all vacant plots will by this time have been dug over, and left as rough as possible, to be mellowed by the weather. Now is the time for the cultivator to plan his system of cropping, so as to take full advantage of the benefits of a proper system of rotation, and according to the shape that system is to assume should be the preparations made during autumn and winter. Practical gardeners very well understand the importance of rotation. Grow cabbage on the same plot all the year round, and every year, and the ground will get so sick of cabbage, and so full of the woevil that causes ambury or club, that the produce will at last be insufficient to pay the cost of carrying it to the kitchen. But there is no occasion to follow an elaborate system; it will suffice to let the crops on the same piece follow each other so that there shall be a thorough change in the families. Thus, after potatoes, which do best without manure, plant a crop that needs heavy manuring, as broccoli or cauliflower, preparing the soil meanwhile by deep trenching, and laying it up for the full influence of winter frost, and (forget it not) for autumn sunshine, for the very light fertilizes by assisting in the decomposition of organic and disintegration of inorganic substances. Lands that lie high and dry may be heavily manured now, and left rough to be sown with early peas, salads, spinach, and other vegetables, to come on quick in the spring of the year. Ground subject to be flooded should not be manured till spring, or the goodness will all be washed away.

MUSHROOM Beds to be spawned. It will be loss of time to hurry the operation by inserting the spawn while heat is too high. The safe temperature is 60° to 70°, if the bed is a few degrees above that, wait a few days without disturbing it, for any disturbance will give a fresh start to the fermentation, and run it up again to a high pitch; and, besides, the more solid the bed, the better, so long as it is not quite as hard as a brick. It is a pity this delicious esculent is not more commonly grown. Every amateur should have a mushroom bed; the whole culture is nearly as simple and certain as growing mustard and cress.

Root Crops.—In storing potatoes, be sure they are dry first; if taken up in wet weather, spread them out in a shed or hothouse, but do not expose them to the light more than can be helped. Parsnips keep best in the ground, to be dug as wanted. Beet to be taken up at once; cut off the leaves an inch above the crown, and avoid bruising or cutting the roots; carrots treat the same; store both in sand or dry earth. Earth-up cardoons; take up scorzonera and salsify, and preserve in sand.

WINTER GREENS.—As there is now much ground vacant, another hunt of the seed-beds will show some plants worth moving to plant out; if they do not make great hearts, they will nevertheless be useful in the spring, and as the weather is very favourable, use up all that can be found, and encourage them by manuring the ground before planting. Collards, savoys, kale, and York cabbage will all pay even now, if plants of any size are to be had.

CAULIFLOWER plants to be put out under hand-lights and in frames; some to be potted for early growth. None of these must be far from the glass however they are kept, and the more often the glass is taken off them the better.

SPINACH.—Thinnings of the winter crop will make very acceptable dishes on the table now. Early-sown spinach is rather too luxuriant this season; probably the latest sown will be the best next February.

Flower Garden.

RHODODENDRONS, AZALEAS, KALMIAS, and other peat plants should be planted at once. They can be selected now with bloom-buds perfected, so that a display next season is ensured. Let there be no stint of proper stuff to plant them in; they are expensive in the first instance, and it is absurd to plant them in such a way that in a few years they are sure to perish. What is said in another note about keeping the balls of roots intact in planting does not apply to these shrubs.

AURICULAS to go to winter quarters. Water sparingly, and give plenty of air.

SEEDS OF GREENHOUSE PLANTS.—This is a good time to sow such things as Pelargonium, Fuchsia, Gazania, Centaurea, Heliotrope, Lantana, Petunia, and other such seeds, as, if the plants are grown on carefully all the winter, they will flower early enough next season to allow of the determination of their true characters and values. When sown in spring it invariably happens that a number of plants have to be housed through the next winter, the ultimate destiny of which is the rubbish-heap. By sowing now, the seed pans are pretty well all that we have to deal with for a few months to come. The practical breeder will perceive how great is the advantage of autumn sowing. But it can only be done where there is a spare shelf in a light dry stove or intermediate house, for in an ordinary greenhouse the seedlings would have no chance at this time of year.

EVERGREEN SHRUBS will move now better than in spring: the earth is warm and the air moist, and they will make fresh roots at once. This is the best time of the whole year to plant American beds, and to make alterations in shrubberies and wildernesses. Not the least occasion to wait for trees to be quite at rest before moving them; the fact is, if they are still growing, and are to be lifted, the sooner they are lifted the better, if only to put a stop to their activities. Hollies will move now with safety, as will aucubas, laurels, thujas, and all kinds of conifers.

FLORISTS' FLOWERS.—Pansies to be protected against slugs, and the ground trod firm between them. Auriculas to be kept moderately moist, and every pot in which the soil has any moss or liverworts to be considered defective in the drainage, and rectified forthwith. Carnations to be smoked if any fly is about them, and to have full exposure to all weathers for the present. Pelargoniums to be kept quiet; let them grow slowly, and use fire-heat only to dry the house in foggy and damp weather. Cinerarias in large pots to have weak liquid manure water; those in small pots to be shifted on, and to be fumigated directly fly is seen about them. Primulas to have a shift if they have filled their pots with roots. Tulip beds to be made ready for planting.

PLANTING.—Extraordinary pains are taken to keep the root-balls of trees intact in the process of transplanting, which we are firmly convinced are needless. In fact, we would always prefer to shake the earth off the roots entirely sooner than plant any tree with a complete ball. The reason why we cannot make room for in this space, but the reminder may be useful to planters who from past experience have doubts about the value of keeping masses of earth about the roots in transplanting. When stripped bare, and every fibre exposed, a tree must be planted with much more care than when lifted with a ball by a machine and dropped into a hole, and that extra care is a gain and an argument for the better practice. Of course this remark does not apply to Americans; they must be moved with balls.

GARDEN PLANTS IN FLOWER.—*Aster fulvis*, *A. foliolosus*, *A. laevis*, *A. eminens*, *A. dumosus*, *A. pulcherrimus*, *A. Nova Angliae*, *A. amplexicaulis*, *Vernonia altissima*, *V. praerata*, *V. scaberrima*, *Teucrium lucidum*, *T. hyrcanicum*, *Salvia virgata*, *S. verbenacea*, *Pyrethrum Chinense*, *Astragalus chlorostachys*, *Campanula stricta*, *Aconitum Chinense*, *Actinomeris proceras*, *Oxytropis brevisstris*, *Hieracium maculatum*, *H. heterophyllum*, *Funkia undulata*, *Oxybaphus chilensis*, *Fumaria leucantha*, *Coreopsis crassifolia*, *C. ferulifolia*, *C. incisus*, *Erodium serotinum*.

THE SEASON AND ITS WORK.—Much now must depend on the weather, and the gardener must make the best of all circumstances. From this time till frost comes, it is the gardener's duty to take advantage of every ray of sunshine, so as to promote the ripening of all kinds of stock, and to keep greenhouse plants exposed to the air as long as it is safe to do so. It is not the cold but the heavy rains which do most injury to tender plants at this season; hence, many things besides true greenhouse plants are all the better for the protection of a frame or cold pit, where they can have shelter, but plenty of air and light. This is a busy month; nearly every kind of winter work may be commenced, and indeed completed, if weather permits. Roses may be moved at once in full leaf, and if left unpruned will soon get root, and be well established before spring. Deciduous trees and hardy fruits may be planted towards the end of the month, for there is no need to wait till every leaf has fallen. Get them into their places while the ground is warm, and a season is saved, and the tree will always be the stronger for it, for the fate of many a tree is sealed in its original planting. Earthwork, too, may now be commenced, and drains laid, turf stacked for forming composts, and deep soiling practised on ground suited to such treatment, so as to have it in ridges in good time to be acted on by frost. The whole of the arrangements for next season should be determined from this time; and in taking up bedders and decorative plants from the borders, their good and bad qualities should all be noted down, so that things that have proved inferior, or that evidently do not suit the soil or situation, may be substituted next season for subjects of higher merit. Every soil has its peculiarities, and one great secret of success, especially in ornamental gardening, is to select varieties that have been proved to succeed in the place; for even geraniums or

calceolarias do well or ill according to the effects of soil or climate upon them. Pits, frames, and houses ought now to be clean and free from the smell of paint and putty. If any repairs have been neglected, see to them at once, and get all sweet and dry without a day's delay; for when we get to October, we are never sure for a week together but that our appliances and manual skill may have a sudden trial. Usually we have mild weather till Christmas, and there seems every probability that this season will be no exception; but the prudent gardener works by anticipation, and is always ready for emergencies.

Fruit Garden and Orchard House.

FRUIT TREES that are making gross shoots may often be compelled to direct their energies to better results by some disturbance of their roots. We have had before now to heel over a whole plantation of plums when a warm autumn and moist winter set them growing again late in the season. Of course large trees must not be so dealt with, but they are more obedient to the wish of the cultivator, and rarely grow too much when in a good bearing state. Make station; ready at once for all trees to be planted. A deep hole opened at the time of planting is a mere mockery; the ground should be deeply stirred now, and left in a very rough condition, but the holes should not be made till wanted, as by that time they might happen to be full of water. It is a good plan when about to purchase trees, to go to the nursery while they are in leaf, and mark all the trees selected with the purchaser's name. We ought not to have to say anything more at present about drainage, but the fact is, so many fruit plantations are everywhere to be found in a miserable condition through the wet state of the soil all winter, that we must repeat the advice to growers of fruit of all kinds. If the heaviest rain does not soon soak away from your fruit borders, and leave the soil so that you can soon after walk on it without sticking to it, then your first business should be to drain! drain! drain! Let no fruit hang after this date; those not ripe must ripen indoors; it is too much to risk to leave them out any longer.

STRAWBERRIES.—Few people suppose that the crowns of strawberry plants require to be ripened as much as the young wood of peach-trees. Yet such is the case. Hence plants potted for forcing are often taken into greenhouses in September, and set growing freely to afford time for the ripening of the crowns; for locked up in them are the embryo fruits. To promote the maturation of the crowns in the open ground, let the plantations be carefully weeded and all the runners removed, and odd plants between the rows be spudded out as weeds; and, lastly, give a light sprinkling of lime, to make an end of the myriads of slugs that now infest the leaves.

WALL TREES will be the better for losing their leaves. But they must not be removed with violence. Pass over them occasionally a new pliable birch-broom, to brush off leaves that are loose at the point. This will expose more and more of the wood to the hardening influence of the sun and atmosphere.

Greenhouse and Conservatory.

AZALEAS must now be put into the coolest places, to have a perfect rest before being again started into growth. Put a mark on those selected for the first bloom, in order that they may have special attention. It is too early, however, to begin forcing any of them yet.

CAMELLIAS that have been out of doors must be housed. Do not allow any of them to go very dry, or the blooms will fall after they have fully expanded. Thin them of the medium-sized buds, leaving the forwardest and the smallest to give a long continuance of bloom.

ERICAS lately housed will be subject to mildew, consequent on the closer air they are compelled to breathe. Apply dustings of sulphur at the first appearance of the pest, and give abundance of air.

BEDDING PLANTS lately housed must have water enough to prevent them flagging till they become somewhat established in their pots, but everything possible must be done to discourage growth. Avoid as far as possible all pruning of soft shoots, and keep the plants as far as is convenient their full length; this will promote the perfect ripening of the lower parts, whereas severe cutting in, combined with the shelter they are now enjoying, would cause them to start in a new growth at the bottom, which at this time of the year is undesirable.

HERRACEOUS CALCEOLARIAS will be full of fly now unless kept scrupulously clean. Look over them carefully. Give them plenty of air, but keep them warm, and always growing near the glass.

PRIMULAS are in many places full of flowers now, though they are scarcely wanted. If there be a lot of old plants about, as there are in most gardens, put them in a warm place to furnish a few flowers for cutting. If no room for them anywhere but in a frame, they will do very well if kept rather close. When flowered out, destroy them, as they are of no use as plants. Keep the young plants near the glass, and regulate the warmth according to their forwardness, and the time when you want them in bloom; of course the colder they are the better.

FUCHSIAS are still in fine condition; at least ours are, and we conclude other people's are. Plants struck in June are now blooming beautifully, and old plants that bloomed early are now in a free second bloom.

ORANGE TREES to be put into winter quarters, and have a thorough cleansing, and the soil in the tubs or pots to be renewed on the surface with something good.

GREENHOUSE PLANTS IN FLOWER.—*Statice Holfordii*, *Bilbergia purpurea*, *Arctotis decumbens*, *Blandfordia intermedia*, *Brugmansia suaveolens*, *Drimia altissima*, *Dumasia pubescens*, *Pleroma elegans*, *Tacsonia molissima*, *Witsenia corymbosa*, *Chirona linoidea*, *Disporum fulvum*, *Passiflora Colvillii*, *P. racemosa*, *Nerine sarniensis*, *Malva campanuloides*, *Salvia splendens*, *Solanum Tweedianaum*, *Thea Bohea*, *Othonna Virginea*, *Adesmia viscosa*, *Dyckia altissima*, *Xanthoxylon piperitum*, *Stenochilus viscosus*.—*Ericas*: *Aurea*, *Pulchella*, *Acuminata*, *Sulphurea*, *Bowieana*, *Pinea discolor*, *Pinea favoidea*, *Pinea pulchella*, *Banksia purpurea*, *Pedunculata*, *Retorta*, *Declifordii*, *Halicababa*, *Tenuiflora alba*, *Comosa rubra*, *Hartnelli*, *Droseroides*, *Rupestris*, *Ovata*, *Pyramidalis*, *Vestita alba*, *Vestita coccinea*, *Hispidula*, *Assurgens*, *Cupressina*, *Eriocephala*, *Mundula major*, *Nivalis*, *Minutiflora*, *Leptocarpa*, *Cerinthoides*, *Glomiflora*, *Lutea*.

Stove and Orchid House.

BEGONIAS for winter flowering deserve the little attention they require now. A nice free soil, containing some proportion of loam—say at least a third—and a warm moist position, are their chief requisites. They never flower freely unless they first grow freely, in which they resemble nearly all other plants under the sun.

STOVE PLANTS.—We suppose that shading was taken down some weeks ago. If any remains up now, it is certainly doing mischief, except in the case of newly imported orchids, and other such special cases. Generally

speaking, stove plants do not need much water now, but they must not go dust-dry. Be not afraid to use fire to keep up a circulation of air in the house, and to prevent damp and mildew, but do not push things into growth by heat; rather promote a resting state as much as possible. Climbers may be slightly cut in for the sake of tidiness, and to favour a free circulation of air; and it would be well to tie and train in pretty close all the well-ripened wood of the season.

ORCHIDS generally are resting, but where growth is proceeding vigorously it must not be checked, or spot will be the result. Keep the house scrupulously clean, and be particularly careful in the use of syringe and water-pot. Do not allow anything to go dust-dry; it is a most unnatural condition for any orchids. Cattleyas and Stanhopeas must have but small supplies of water now, and the temperature must be reduced.

Forcing Pit.

FORCING to be prepared for according to the demand for asparagus, sea-kale, rhubarb, &c. Take up all the roots that are to be used in the first batch, and lay them in by the heels; the roots force better if taken up some little while beforehand, especially for the earliest supplies, for which the plants are still in a somewhat active state, and needing to be artificially rested. This method answers also to afford an opportunity for trenching the ground, as every piece cleared of roots can be deeply stirred, manured, left a little to sweeten and pulverize, and be planted if necessary with roots for succession crops.

PEACHES.—Make ready to start the earliest house. The preliminaries are clean glass and woodwork; spiders away; flues fit for fire, and water-pipes cured of leaking; the trees pruned in and tied out, and all the stems and branches washed with sulphur and tobacco. As "everybody knows" how to make this wash, the following recipe is quite superfluous, nevertheless we insert it:—

Wash for Peach, Apricot, and Nectarine Trees, Vines, &c.—Take 2 lb. soft soap, 2 lb. flowers of sulphur, 1 lb. strong shag tobacco, 3 oz. nux vomica, in powder. Boil the tobacco for an hour in a gallon of water. Pour off the liquor, and squeeze the tobacco of the last drop. Add the other ingredients, and mix them thoroughly. Add five gallons of water. You will have about six gallons in all, costing less than a shilling a gallon. It is cheaper than Gishurst, and more effectual.

FIGS that have ripened off their fruit must be allowed to go rather dry at the root, to promote a perfect ripening of the wood; but where the trees are still swelling their fruit, they must have the aid of manure-water.

PINES.—It is full time now to separate fruiting plants from successional, as they no longer do well together. The fruiterers are to be valued much, and they are pretty sure to command proper attention. They require a steady heat of 5° to 10° more than the successional; the latter will do well at 60° night and 70° day, with a rise of 7° in sunshine. Be very cautious in giving liquid manure to plants swelling fruit, as at this time of year, when solar light is deficient, an extra dose of manure-water will cause blackness at the heart of the fruit, and render it worthless.

VINES to be forced early must now be robbed of every leaf, if they are absurd enough to have any leaves on them. Some people invite the red spider to clear off the leaves, which is a very good plan, barring the fact that the spider takes also a little strength out of the vine, and usually stays till spring to thin the crop. Vines that have properly lost their leaves, and that have nice hard brown canes, may be pruned, but if there are signs of bleeding wait another week or two. Grapes not yet ripe must be ripened off at once. It will not do to delay the process. Let them hang after they are ripe if you like, but do not allow them to ripen at a pace so slow that rotting will overtake it, and presently produce pulp instead of berries. Nor can any grapes be expected to ripen now without fire-heat, and plenty of fresh air; give them both, and the result will be perfect finishing and a good flavour.

Replies to Queries.

Thomas Eames—It is better always for the pipes to rise, but we have often shown that they may be laid at a dead level. The man who says it is not material whether they rise or fall talks nonsense. We do not undertake to reply to letters privately; when we are mad enough to offer to do so, will be time enough for correspondents to expect it.

Cyclamen Europæum—J. D. P., Gloucester.—The only way to multiply this pretty species is by seeds. Secure them as soon as ripe, and sow them directly in pans filled with sandy peat, covering the seed very slightly. Place the pans in a cold frame, and, if quite convenient, grow the plants in a cold frame the whole year round. Pot them separately when large enough; never allow them to get quite dry; and, generally speaking, treat them much the same as hardy ferns.

Tree Ferns—Scotch Gardener.—The seedling ferns on your tree-fern stems will do no harm at all; when they begin to be fruitful they may be named, and not before, with any certainty. You will probably not find anything rare amongst them. The spores were no doubt deposited on the stems before the latter were removed from their native sites, therefore you may consider the little plants to be genuine importations. In answer to the second question, we are bound to say that we have no faith at all in collections of seed made in foreign parts by persons unskilled in collecting. They generally send home dead samples of subjects already in cultivation, and the postage amounts to more than the same seeds (fit for use) can be purchased of the seedsmen. Of course, it is not for us to discourage you or your friend; but as you ask for advice what seeds he should look for, our advice is, none at all.

Cerastium tomentosum.—Constant Reader.—Your soil must either be too poor for the plant, which is very unlikely, for it is very accommodating, or it is injured by the wire-worm or the larva of Tipulaeacea. Take up a few plants and search amongst their roots, and probably the cause of the early dying-off of the plant may be discovered. As to which of the two popular kinds of cerastium is the best, must depend on taste and circumstances. Mr. McElroy declared in one of his papers lately in favour of *C. Biebersteinii*; but we are of opinion that for all ordinary purposes *C. tomentosum* is the best: the first is woolly gray, the second silvery gray. In many instances the first might be the best, but we think the second will always take the lead. *C. tomentosum* is usually clipped close back at the end of June in gardens where it grows freely, and it immediately presents a second and very beautiful growth. Pray do not apologize; it is a pleasure to answer so far as we are able such plainly-stated questions as yours.

W. C.—Messrs. Jackson and Son, Nurserymen, Woking, Surrey.

T. W. H.—The plants will certainly need a little more attention beyond watering to fit them for a good position at a show in November. The fact is, specimen chrysanthemums are never quite finished as to tying, training,

&c., &c., until they are actually staged; but from the present time what they demand is watching more than working.

Young Propagator.—We have never known the necessity of grafting the Crowea, as when on its own roots it grows freely enough. Perhaps you mean Correa; the varieties of this genus are generally grafted on Correa inflata. The choicer kinds of rhododendron, such as Nuttall, Falconeri, &c., are usually grafted on the common Pontic stock. There is an easy way of obtaining all the choicer kinds on their own roots, and that is to raise them from seed, which may be obtained good from the first-class seedsmen. These finer kinds come pretty true from seeds, and when they vary slightly from typical forms, the variation is as likely to be an advantage as otherwise.

E. J.—Your plant is the Golden Rod, *Solidago altissima*, a good shrubby plant.

Correspondence.

LABELS AT EXHIBITIONS.—When at an exhibition lately, there was one thing which struck me as needing some improvement, and the fault is common nowadays. I mean the imperfect way in which the labels are written, betraying such a want of knowledge of spelling as almost to destroy identity. Would it not be better for the promoters of exhibitions to undertake this task, and prepare beforehand legibly written cards (the sorts exhibited do not vary much in each show), which would be an immense relief to visitors, who would not be obliged to unravel a mystery contained in the hieroglyphics one constantly sees on a narrow slip of paper. I am not finding fault with gardeners, who have enough to do in preparing the things for the show; but it is in little matters of detail, as you have often said in your papers, that the success of shows in general depends. I have seen lately such labels as the following: "Emperor Allick," for Emperor Alexander; "Glore de Monday," for Gloria Mundi; "Seelenar," for Cellini; "Gloridijon," for Gloire de Dijon, &c., &c. CORRECT LABEL.

[Printed labels would go a great way to cure this evil if prepared beforehand under the direction of persons versed in the business; but the perfect cure is the schoolmaster, or, in other words, the education of gardeners. Those of them who read learn also to spell; the writers of the ridiculous labels are, generally speaking, men who never read, consequently never see the names of plants, flowers, &c., &c., in print; but having caught the name imperfectly by hearing, spell it out to the best of their ability.]

CATALOGUES.

E. G. HENDERSON AND SON, WELLINGTON ROAD, ST. JOHN'S WOOD. *Catalogue of Bulbs, Flower Roots, Roses, &c. &c.*—This is an enlarged form of the usual autumnal list from this house. It contains the usual lists of bulbs, admirably arranged, and accompanied with notes on cultivation, &c. Next, lists of roses, fruit-trees, hardy climbing plants, hardy spring-flowering plants, descriptions of some new variegated trees, new pelargoniums, new fuchsias, new verbenas, &c., &c., finishing up with well-engraved portraits of some of the principal novelties now in course of distribution. One of the most important catalogues of the season.

WILLIAM WOOD AND SON, MARESFIELD, NEAR UCKFIELD, SUSSEX. *General Catalogue of Trees and Shrubs. Select List of Dutch Flower Roots. Descriptive Catalogue of Roses.*—Three well-prepared and beautifully-printed lists, adapted for all classes of cultivators and purchasers, and comprising in every class the best varieties known. In the catalogue of roses occurs the following advice on planting them: "When they are to be placed out singly on lawns, or in beds amongst other plants, a hole should be made, about eighteen inches deep, and large enough to contain half a wheel-barrowful of compost; two-thirds of this should be strong turfy loam (if it can be procured from an old pasture it is preferable), and one-third well-decomposed animal manure; these should be thoroughly mixed together; should the ground be dry at the time of planting, or if it is done in spring, a liberal watering should be given before the soil is all filled in around the plants; and Standards should be securely staked, to prevent the winds from moving them, which is very injurious. When beds are to be planted, the ground should be deeply trenched, and afterwards a good dressing of manure should be applied; a small quantity of the compost recommended above may also be added around each plant. As roses seldom thrive well in soils that have previously grown them for a number of years, it is advisable that when old beds are renewed, the soil should be removed to the depth of eighteen inches, and its place supplied with the above mixture. When a piece of ground is set apart for the exclusive cultivation of roses, the most open situation that is available should be selected; if wet, it should be drained; if it is inconvenient to use tiles, a layer of from four to six inches deep of broken stones, or any other coarse material, will answer the purpose. This done, the ground should be trenched as deeply as the nature of the soil will admit; the beds may then be formed according to taste or circumstances, and the planting may be proceeded with as recommended above. November is the best month for transplanting; but it may be safely done from October to March; it is not advisable to prune at the time of, nor immediately after, planting. The first season the plants should all be headed back to two or three buds upon each shoot; this will ensure a vigorous growth."

BUTLER, McCULLOCH, AND CO., COVENT GARDEN MARKET. *Autumn Catalogue of Dutch and Cape Bulbs, Flower, Vegetable, and Agricultural Seeds.*—A large list, containing many valuable subjects for the kitchen and flower gardens, besides the usual Dutch and Cape roots. In the bulb lists are several rarities, such as *Triteleja uniflora*, *Camassia esculenta*, *Zephyranthes candida*, &c. There is a good list of Gladioli.

A. VERSCHAFFELT, RUE DE CHAUME, GHENT. *Price Current for Autumn, 1867, and Spring, 1868.*—A very handy review of M. Verschaftolt's collections, comprising good selections of arborescent and herbaceous peonies, ornamental trees, rhododendrons, camellias, azaleas, together with the usual lists of stove and greenhouse plants.

R. EDWARDS AND SON, NITHALL, NEAR NOTTINGHAM. *Priced Catalogue of Exotic and British Ferns*—This admirably arranged catalogue will be found of great service to cultivators of ferns, both on account of the numerous interesting varieties described, and the complete view it affords of the British species. The list of stove and greenhouse species is sufficiently extensive for all ordinary purposes.

SCENE—COLLEGE GARDEN.—Head of College.—"I really cannot understand, Parsley, how you manage to get the celery so white." Gardener (deliberately).—"I tell you what it is, sir—take away yer Greek and Latin and you knows nothink."—*July.*

The Gardener's Magazine.

SATURDAY, OCTOBER 12, 1867.

SUB-TROPICAL GARDENING has been subjected to a severe test in the season now closing, and there cannot remain, in the mind of any one competent to form an opinion on the subject, a single doubt of its adaptability for our climate, when its requirements are judiciously observed, and the risks attending it are duly weighed beforehand. We are indebted to Mr. Gibson, the talented and largely-experienced superintendent of Battersea Park, for many grand lessons in this system of out-door embellishment, and we have been once more privileged to testify, by our report on the Battersea Park embellishments, to the complete success of his experiments, and the splendour of the results attained. We should have nothing to say in praise of this system did its chief merit consist in merely keeping tropical or sub-tropical plants alive during a short period of the summer in the open air of this country. The merit of the system, when science and taste are conjoined, is that it imparts to our garden scenes a richness and novelty wholly unattainable by other means. The flat carpet colouring, which is the bane of the bedding system as ordinarily practised, is broken up, the eye is carried away from the monotony of surface and the satiety of colour to grand towering masses of the richest forms of vegetation. There may be, and there is something of bizarre perceptible in many of the features of the system as we are best accustomed to its developments, but after heavily discounting its total value, the residuum is glorious and compels our admiration and eulogy. The great sin of the bedding system as commonly understood and practised is sameness. Gorgeous masses of colour surprise at first and satiate at last. In the public promenade garden many things are allowable that would be quite out of place in a private garden, and the prevailing folly is the imitation in quiet places of effects adapted only to gardens visited by crowds, where surprises are called for, where colour is sometimes more attractive than beauty, where a hundred thousand scarlet geraniums will give more satisfaction than half a dozen grand groups of the noblest plants in the world. The million twinkling coloured lamps employed to make "fairytowns" in the old Vauxhall gardens were a constant success, people went there in thousands to see them; but, in this particular, common sense so far prevailed that very few of the thousands ever attempted to imitate the vistas in their own private retreats, for the simple reason, perhaps, that it was out of their power. In respect of bedding effects, however, the lack of power has not always been sufficient to deter people from attempts at imitating the bedding displays at Kew or the Crystal Palace, and hence we find in many gardens where variety would be a boon, because of the unfailing interest arising out of the presentation of many forms of vegetable beauty, a miserable repetition of a dozen or so varieties of bedding plants served up *ad nauseum*, on the plan of a little book lately published under the title of "A Thousand Ways of Cooking Yarmouth Bloaters." Now the sub-tropical system will tend to cure this wherever it is practised in a broad manner. The first necessity is an assemblage of valuable and beautiful plants, differing in character from the vegetation we are most accustomed to, and furnishing of necessity food for the mind, while affording to the eye an intensity of delight. We have been cautious of recommending the adoption of this system in private gardens; indeed, it is our custom to be cautious in respect of everything new, for in no other department of art has the mere love of novelty been accompanied with so much mischief as in horticulture. But we have no more scruples on the subject. This system is adapted for any place within the boundaries of the isle, provided the persons who elect to practise it possess the needful means, ability, and taste to carry it out in its integrity, and in doing so desire to depart from the common carpet colouring which for many years past has satisfied so many of our garden-loving countrymen.

We are indebted to Mr. Gibson not only for the development of the system as a whole, but for some curious results in detail. Battersea Park, for example, might have been extremely grand this year (as it was) without a bed of Musas; No. 128, NEW SERIES.—VOL. X.

but no practical horticulturist could traverse the ground, making note of individual features, without experiencing a delightful surprise at seeing the Banana *flowering and fruiting* in the open ground with the health and vigour of a British plant; yet it might have been seen there, and was seen by tens of thousands of people, a large majority of whom were, of course, quite uneducated to the perception of something wonderful in this case. The idea of a bank of *Nootopteris Australasica* in the open air may cause some fern-growers to take a deeper breath than ordinary; but here it passed out of the region of ideas into that of fact. *Cannas* and *Erythras* we have become accustomed to as bedding plants, but we must never forget the establishment of these as nearly hardy plants, for many of the *Cannas* remain from year to year untouched, and the plants live through the winter in the open ground, with only the protection of a few inches of litter, and actually supersede geraniums in respect of hardiness. *Aralias* take an important place, too, as nearly hardy trees, the paper *aralia* being quite capable of enduring the severities of a British winter unhurt in this southern latitude; and as for *Wigandias*, *Dracenas*, and *Caladiums*, they occasion no more trouble to propagate them in quantity, and plant them out annually, than years ago was bestowed upon subjects of most trivial importance and insignificant value—or, to put the case in another way, than the ordinary run of half-hardy plants.

A peculiar advantage of the breaking up of the flat system of colouring, is that many hardy plants become available for embellishment that cannot be made to harmonize with the established geranium, *calceolaria*, and *verbena* system. Why should we lose from our parterres and borders the splendid *lobelias* of the *Cardinale* section? Why should we shut out from the most richly-dressed grounds the many noble grasses and bamboos, that lend such peculiarly graceful outlines to relieve masses of colour? The hardy and nearly hardy plants available for embellishing the garden, where the carpet system has been voted tame and tawdry, are far too numerous for classification in this place; but we can take comfort of the fact that hardy plants have had a considerable share of attention in these columns, and the lovers of such good and cheap things only need to read what has been written to be fully informed of the species and varieties that are best adapted for grand displays. The sub-tropical system is not without its difficulties, and that is an advantage. It demands skill and taste, and we desire to see these attainments encouraged, for they are directly associated with the exaltation of human character; to a certain extent, too, means are necessary, and this is not an evil, for those who are not blessed with means have but to be content with cheaper methods; and we have done our best to show that the garden may be made a place of delightful resort without the aid of the purse of *Cræsus*.

THE ROYAL GARDENS AT KEW are acquiring an unenviable notoriety by the number of young men whose health is shattered by short terms of service there. Four assistants in the herbarium have in succession resigned on account of ill-health, three of whom are dead, and the fourth, Mr. Hemsley, is quite incapacitated. The plant-houses ruin many young men of spirit and promise. They go there strong and hopeful; they soon after leave, with constitutions ruined, and with little other hope than a quick consignment to the grave. There must be something wrong, and worth inquiring into. In all gardens the health of practical cultivators is exposed to a certain degree of risk, and the risk is usually in a direct ratio with the extent of glass and heating apparatus. Orchid growers do not calculate on attaining to a great age; industrious plantmen anticipate disablement some time ere they make their threescore and ten; but Kew Gardens appear to a great disadvantage, in respect of the health of persons employed there, when compared with any similar establishments. We trust Mr. Hemsley may yet have before him many years of happiness and usefulness, though he has left Kew with a constitution apparently ruined. A pension of sufficient amount to enable him to rest and seek physical repair, is undoubtedly his due for the health and energy he has given in the service of science at the Kew herbarium, and this we may suppose it possible for Government to bestow, if proper representations are made, and the claim is pressed with prudence.

A "NAPOLEON'S WILLOW" AT KEW HAS BEEN CUT DOWN. This tree was planted about forty years ago, and has ever since been one of the most attractive objects in the gardens, hundreds of Englishmen looking upon it as a national historic trophy, whilst Frenchmen might be seen reverently taking off their hats, and even going down on their knees before it. Some years ago, a frenzy of enthusiasm in respect of this tree seized the London public; and on several Sundays in succession swarms of people went to Kew to see it; once, indeed, in so demonstrative a manner that the crowd forced their way through a closed gate in quest of the object of their curiosity. "St. Helena Willows" abound; there are, in fact, thousands in the suburbs of London alone, to say nothing of examples in almost every

good garden throughout the country. But the Kew willow was one of the most worthy, because it was not, like many called Napoleon and St. Helena willows, reared from a cutting taken at one or two removes from the original, but came direct from one of the trees that overshadowed Napoleon's tomb prior to the removal of the last stumps of those trees in 1840.

THE SHOOTING OF SONG-BIRDS.—At the annual meeting of the Western District Cottage Gardening Society, held at Penzance, Mr. Bolitho, the high sheriff of the county, said: "Whoever is an admirer of gardens must be an admirer of song-birds; and I am very grieved to say that in this neighbourhood there is a large diminution in our best songsters. The thrush, if we don't take care, will become extinct. So many guns are levelled against every thrush, and so many boys look after the nests, that we are actually threatened with the extermination of this charming bird of song. It was but a little time ago that I met a man in the country—a very respectable man, and well known to some of you—and said to him, 'What have you got there?' He replied, 'Only a couple of greybirds I have shot for the ferret!' I do ask all who take an interest in our gardens to show some sympathy for our song-birds, not only by taking care not to buy any blackbirds or grey-birds, but if you happen to know a thrush's nest, or a blackbird's, or a black-cap's, by not telling your neighbours where it is. Don't follow the example of a very excellent friend of mine, who put it in the newspapers that a blackcap's nest was in a certain neighbourhood, so that all the boys of the place were directed to it, and this beautiful little warbler was lost to us. Why, even the robins are getting scarce; yes, the little robins who were our early companions, and in whom all take such delight—the little birds who have been immortalized by so many poets, but by none more than one of our county—Coleridge, of Kenwyn—

The blackbird's song is sweet at night;
And hers, who gay ascends,
Filling the heavens far and wide, are sweet;
But none so blends as thine
With calm decay and peace divine.

THE SALE OF UNSOUND FRUIT.—A correspondent of the *Morning Star* says there is a wise law prohibiting the sending to market for sale of meat unfit for human food, and imposing a penalty of fine or imprisonment for so doing. Why is there not a similar enactment for the fruit trade? Physicians inform us that a proper quantity of ripe and good fruit, eaten in season, is good for health; but that unripe or decayed fruit is almost as bad as taking poison. What says the Registrar-General's last report? In the eleven weeks from July 6th to September 23rd, no less than 1,867 children, besides many adults, died of diarrhoea! Now, from the quality of the fruit I see retailed to the poor in many districts of this metropolis, I can have no hesitation in saying that the greater number of those deaths took place in consequence of eating unripe and decayed fruit, and yet the law takes no means to prevent this unwise waste of life! Recollect these 1,867 deaths represent but a third or fourth of those who were attacked! Will you bring this subject under the notice of the proper authorities, and confer a favour on the public?

THE VALUE OF NETTLES.—Sow and plant nettles, says Mr. Xavier Garenne, a French writer, and all the lands in the south and the wastes in other parts of France will be converted into green and profitable fields. He wonders that the world is so slow to learn the great economic value of this robust plant, which will grow everywhere. Raise nettles, and in the young tops thereof you will have a delicious and early vegetable for your dinner-table, and abundance of early green food for your cattle. The milk of cows is improved by a diet of nettles, and the beef of cattle fed on nettles is superior to all other. Nettles, too, are of remarkable efficacy in restoring broken down horses to vigour. And in commerce their value is great; for they can be treated as hemp, and spun into lines and ropes, and woven into cloth. France has grand schemes of planting in contemplation, and it may be that the long-neglected *Urtica* will be taken into favour.

CULTIVATION OF PERFUMES.—From a paper upon the cultivation of flowers and the manufacture of perfumery at Nice, by Mr. A. O. Aldis, United States Consul at that port, we learn that the export of perfumery from Nice, Grasse, and Cannes to the United States last year amounted to about 40,000 dollars. There are six or seven manufactories at Nice, the same number at Cannes, and at Grasse about sixty. These manufacturers supply perfumers in all quarters of the world. There is a distinction between the manufacturer and the perfumer. The business of the former is to extract from the flowers their essential oils. The perfumer buys these oils, pomades, and extracts, and compounds them in various ways.

TOWN HALL AND PARKS AT PRESTON.—On Thursday the opening of the Town-hall and two new parks was inaugurated by the Duke of Cambridge with considerable public ceremony. The new Town-hall has been about five years in building. The architecture is Gothic, of the early style of the fourteenth century. The entire cost of the Town-hall will be about £70,000. The new parks are situated on the south-western side of the town, and can easily be seen by parties entering the town from the south by railway. One of them is called Avenham Park, and the other Miller Park. The land for Miller Park has been given on certain conditions to the town by the late Alderman T. Miller, of Preston. Both parks have been beautifully laid out according to designs by Mr. Milner, landscape gardener. It appears that in the ceremonies and speeches connected with the opening of the Preston Town-hall and Parks, some injustice was done in the total omission of reference to the grant of money under the provisions of the Public Works Act of 1863, and the labour of the distressed operatives during the years of the cotton famine, to both of which their formation is largely owing. It is true that the Corporation and Mr. Miller have acted generously, and deserve all the praise that has been bestowed upon them for their joint labours in the improvement of Preston; but the Preston Parks are in great part the result of the cotton famine, and that fact must be kept in remembrance.

SUPERB PENNY-A-LINING.—A country contemporary, describing a village school treat, indulges in the following bit of "tall writing": "The weather was most lovely the greater part of the day, but towards the evening his Pluvial Highness shed tears of joy on the happy occasion, and with pearly drops besprinkled the grass. Seeing such feeling manifested by the gods, although of dawning tendency, the spirits of the participators and the enthusiasm of the spectators rose in proportion; and although portentous clouds cast their shadows, yet, ere the zephyr kissed the twilight beams, the sun burst forth in all his splendour, gladdening the lovely landscape, and adding lustre to the scene."

A WORD TO THE WISE.—A remarkable word of warning has just been furnished by the death of a gentleman, who, while staying in Killarney, was killed by a falling tree. He was last year insured with the Accident Insurance Company, but he did not renew his policy this year.

THE PHILOSOPHY OF BIRDS' NESTS.

BY ALFRED R. WALLACE, F.Z.S., ETC.

Birds, we are told, build their nests by *instinct*, while man constructs his dwelling by the exercise of *reason*. Birds never change, but continue to build for ever on the self-same plan; man alters and improves his houses continually. Reason advances; instinct is stationary. This doctrine is so very general that it may almost be said to be universally adopted. Men who agree on nothing else, accept this as a good explanation of the facts. Philosophers and poets, metaphysicians and divines, naturalists and the general public, not only agree in believing this to be probable, but even adopt it as a sort of axiom that is so self-evident as to need no proof, and use it as the very foundation of their speculations on instinct and reason. A belief so general, one would think, must rest on indisputable facts, and be a logical deduction for them. Yet I have come to the conclusion that not only is it very doubtful, but absolutely erroneous; that it not only deviates widely from the truth, but is in almost every particular exactly opposed to it. I believe, in short, that birds do *not* build their nests by instinct; that man does *not* construct his dwelling by reason; that birds do change and improve when affected by the same causes that make men do so; and that mankind neither alter nor improve when they exist under conditions similar to those which are almost universal among birds.

Let us first consider the theory of reason, as alone determining the domestic architecture of the human race. Man, as a reasonable animal, it is said, continually alters and improves his dwelling. This I entirely deny. As a rule, he neither alters nor improves, any more than the birds do. What have the houses of most savage tribes improved from, each as invariable as the nest of a species of bird? The tents of the Arab are the same now as they were two or three thousand years ago, and the mud villages of Egypt can scarcely have improved since the time of the Pharaohs. The palm-leaf huts and hovels of the various tribes of South America and the Malay Archipelago, what have they improved from since those regions were first inhabited? The Patagonian's rude shelter of leaves, the hollowed bank of the South African Earthmen, we cannot even conceive to have been ever inferior to what they now are. Even nearer home, the Irish turf cabin and the Highland stone shanty can hardly have advanced much during the last two thousand years. Now, no one imputes this stationary condition of domestic architecture among these savage tribes to instinct, but to simple imitation from one generation to another, and the absence of any sufficiently powerful stimulus to change or improvement. No one imagines that if an infant Arab could be transferred to Patagonia or to the Highlands, it would, when it grew up, astonish its foster-parents by constructing a tent of skins. On the other hand, it is quite clear that physical conditions, combined with a degree of civilization arrived at, almost necessitate certain types of structure. The turf, or stones, or snow—the palm-leaves, bamboo, or branches, which are the materials of houses in various countries, are used because nothing else is so readily to be obtained. The Egyptian peasant has none of these, nor even wood. What, then, can he use but mud? In tropical forest countries, the bamboo and the broad palm-leaves are the natural materials for houses, and the form and mode of structure will be decided in part by the nature of the country, whether hot or cool, whether swampy or dry, whether rocky or plain, whether frequented by wild beasts, or whether subject to the attacks of enemies. When once a particular mode of building has been adopted, and has become confirmed by habit and by hereditary custom, it will be long retained, even when its utility has been lost through changed conditions, or through migration into a very different region. As a general rule, throughout the whole continent of America, native houses are built directly upon the ground—strength and security being given by thickening the low walls and the roof. In almost the whole of the Malay Islands, on the contrary, the houses are raised on posts, often to a great height, with an open bamboo floor; and the whole structure is exceedingly slight and thin. Now, what can be the reason of this remarkable difference between countries many parts of which are strikingly similar in physical conditions, natural productions, and the state of civilization of their inhabitants? We appear to have some clue to it in the supposed origin and migrations of their respective populations. The indigenes of tropical America are believed to have immigrated from the north—from a country where the winters are severe, and raised houses with open floors would be hardly habitable. They moved southwards by land along the mountain ranges and uplands, and in an altered climate continued the mode of construction of their forefathers, modified only by the new materials they met with. By minute observations of the Indians of the Amazon Valley, Mr. Bates arrived at the conclusion that they were comparatively recent immigrants from a colder climate. He says:—"No one could live long among the Indians of the Upper Amazon without being struck with their constitutional dislike to the heat. . . . Their skin is hot to the touch, and they perspire little. . . . They are restless and discontented in hot dry weather, but cheerful on cool days, when the rain is pouring down their naked backs." And, after giving many other details, he concludes, "How different all this is with the Negro, the true child of tropical climes! The impression gradually forced itself on my mind that the Red Indian lives as an immigrant or stranger in these hot regions, and that his constitution was not originally adapted, and has not since become perfectly adapted to, the climate."

The Malay races, on the other hand, are no doubt very ancient inhabitants of the hottest regions, and are particularly addicted to forming their first settlements at the mouths of rivers or creeks, or in land-locked bays and inlets. They are a pre-eminently maritime semi-aquatic people, to whom a canoe is a necessary of life, and who will never travel by land if they can do so by water. In accordance with these tastes, they have built their houses on posts in the water, after the manner of the lake-dwellers of ancient Europe; and this mode of construction has become so confirmed, that even those tribes who have spread far into the interior, on dry plains and rocky mountains, continue to build in exactly the same manner, and find safety in the height to which they elevate their dwellings above the ground.

These general characteristics of the abode of savage man will be found to be exactly paralleled by the nests of birds. Each species uses the materials it can most readily obtain, and builds in situations most congenial to its habits. The wren, for example, frequenting hedgerows and low thickets, builds its nest generally of moss, a material always found where it lives, and among which it probably obtains much of its insect food; but it varies sometimes, using hay or feathers when these are at hand. Rooks dig in pastures and ploughed fields for grubs, and in doing so must continually encounter roots and fibres. These are used to line its nest. What more natural! The crow, feeding on carrion, dead rabbits, and lambs, and frequenting sheep-walks and warrens, chooses *fur* and *wool* to line its nest. The lark frequents cultivated fields, and makes its nest, on the ground, of grass lined

with *horse-hair*—materials the most easy to meet with, and the best adapted to its needs. The kingfisher makes its nest of the *bones* of the fish which it has eaten. Swallows use clay and mud from the margins of the ponds and rivers over which they find their insect food. The materials of birds' nests, like those used by savage man for his house, are, then, those which come first to hand; and it certainly requires no more special instinct to select them in the one case than in the other. But, it will be said, it is not so much the materials as the form and structure of nests that vary so much, and are so wonderfully adapted to the wants and habits of each species; how are these to be accounted for except by instinct? I reply, they may be in a great measure explained by the general habits of the species, the nature of the tools they have to work with, and the materials they can most easily obtain, with the very simplest adaptations of means to an end quite within the mental capacities of birds. The delicacy and perfection of the nest will bear a direct relation to the size of the bird, its structure and habits. That of the wren or the humming-bird is perhaps not finer or more beautiful in proportion than that of the blackbird, the magpie, or the crow. The wren, having a slender beak, long legs, and great activity, is able with great ease to form a well-woven nest of the finest materials, and places it in thickets and hedgerows which it frequents in search for food. The titmouse, haunting fruit-trees and walls, and searching in cracks and crannies for insects, is naturally led to build in holes where it has shelter and security; while its great activity, and the perfection of its tools (bill and feet), enable it easily to form a beautiful receptacle for its eggs and young. Pigeons, having heavy bodies, and weak feet and bills (imperfect tools for forming a delicate structure), build rude flat nests of sticks, laid across strong branches which will bear their weight and that of their bulky young. They can do no better. The *Caprimulgide* have the most imperfect tools of all, feet that will not support them except on a flat surface (for they cannot truly perch), and a bill excessively broad, short, and weak, and almost hidden by feathers and bristles. They cannot build a nest of twigs or fibres, hair or moss, like other birds, and they therefore generally dispense with one altogether, laying their eggs on the bare ground, or on the stump or flat limb of a tree. The hooked bills, short necks and feet, and heavy bodies of parrots render them quite incapable of building a nest like most other birds. They cannot climb up a branch without using both bill and feet; they cannot even turn round on a perch without holding on with their bill. How, then, could they inlay, or weave, or twist the materials of a nest? Consequently, they all lay in holes of trees, the tops of rotten stumps, or in deserted ants' nests, the soft materials of which they can easily hollow out.

Now I believe that throughout the whole class of birds the same general principles will be found to hold good, sometimes distinctly, sometimes more obscurely apparent, according as the habits of the species are more marked, or their structure more peculiar. It is true that, among birds differing but little in structure or habits, we see considerable diversity in the mode of nesting, but we are now so well assured that important changes of climate and of surface have occurred within the period of existing species, that it is by no means difficult to see how such differences have arisen. Habits are known to be hereditary, and as the area now occupied by each species is different from that of every other, we may be sure that such changes would act differently upon each, and would often bring together species which had acquired their peculiar habits in distinct regions and under different conditions.

But, it is objected, birds do not *learn* to make their nest as man does to build, for all birds will make exactly the same nest as the rest of their species, even if they have never seen one, and it is instinct alone that can enable them to do this. No doubt this would be instinct if it were true, and I simply ask for proof of the fact. This point, although so important to the question at issue, is always assumed without proof, and even against proof, for what facts there are, are opposed to it. Birds brought up from the egg in cages do not make the characteristic nest of their species, even though the proper materials are supplied them, and the experiment has never been fairly tried, of turning out a pair of birds so brought up into an enclosure covered with netting, and watching the result of their untaught attempts at nest-making. With regard to the song of birds, however, which is thought to be equally instinctive, the experiment has been tried, and it is found that young birds never have the song peculiar to their species if they have not heard it, whereas they acquire very easily the song of almost any other bird with which they are brought up. It is also especially worthy of remark that they must be taken out of hearing of their parents very soon, for in the first three or four days they have already acquired a knowledge of the parent notes, which they will afterwards imitate. This shows that very young birds can both hear and remember, and it would be very extraordinary if they could live for days and weeks in a nest and know nothing of its materials and the manner of its construction. During the time they are learning to fly and return often to the nest, they must be able to examine it inside and out in every detail, and as their daily search for food invariably leads them among the materials of which it is constructed, and among places similar to that in which it is placed, is it so very wonderful that when they want one themselves they should make one like it? Again, we always assume that because a nest appears to us delicately and artfully built, that it, therefore, requires much special knowledge and acquired skill (or their substitute, instinct) in the bird who builds it. We forget that it is formed twig by twig and fibre by fibre, rudely enough at first, but crevices and irregularities, which must seem huge gaps and chasms in the little eyes of the builders, are filled up by twigs and stalks pushed in by slender beak and active foot, and that the wool, feathers, or horsehair are laid thread by thread, so that the result seems a marvel of ingenuity to us, just as would the rudest Indian hut to a native of Brohddignag.

But look at civilised man! it is said: look at Grecian and Egyptian and Roman and Gothic and modern architecture! What advance! what improvement! what refinements! This is what reason leads to, whereas birds remain for ever stationary. If, however, such advances as these are required to prove the effects of reason as contrasted with instinct, then all savage and many half-civilized tribes have no reason, but build instinctively quite as much as birds do.

Man ranges over the whole earth, and exists under the most varied conditions, leading necessarily to equally varied habits. He migrates—he makes wars and conquests—one race mingles with another—different customs are brought into contact—the habits of a migrating race are modified by the different circumstances of a new country. The civilized race which conquered Egypt must have developed its mode of building in a forest country where timber was abundant, for there is no possibility of the idea of cylindrical columns originating in a country destitute of trees. The pyramids might have been built by an indigenous race, but not the temples of El Uxor and Karnak. In Grecian architecture, almost every characteristic

feature can be traced to an origin in wooden buildings. The columns, the architrave, the frieze, the fillets, the cantilevers, the form of the roof, all point to an origin in some southern forest-clad country, and strikingly corroborate the view derived from philology, that Greece was colonised from north-western India. But to erect columns and span them with huge blocks of stone or marble is not an act of reason, but one of pure unreasoning imitation. The arch is the only true and reasonable mode of covering over wide spaces with stone, and, therefore, Grecian architecture, however exquisitely beautiful, is false in principle, and is by no means a good example of the application of reason to the art of building. And what do most of us do at the present day but imitate the buildings of those that have gone before us. We have not even been able to discover or develop any definite mode of building best suited for us. We have no characteristic national style, and to that extent are even below the birds, who have each their characteristic form of nest, exactly adapted to their wants and habits.

That excessive uniformity in the architecture of each species of bird which has been supposed to prove a nest-building instinct we may, therefore, fairly impute to the uniformity of the conditions under which each species lives. Their range is often very limited, and they very seldom permanently change their country so as to be placed in new conditions. When, however, new conditions do occur, they take advantage of them just as freely and wisely as man could do. The chimney and house swallows are a standing proof of a change of habit since chimneys and houses were built, and in America this change has taken place within about three hundred years. Thread and worsted are now used in many nests instead of wool and horse-hair, and the jackdaw shows an affection for the church steeple which can hardly be explained by instinct. The Baltimore oriole uses all sorts of pieces of string, skeins of silk, or the gardener's bass, to weave into its fine pensile nest, instead of the single hairs and vegetable fibres it has painfully to seek in wilder regions; and Wilson believes that it improves in nest-building by practice, the older birds making the best nests. The purple martin of America takes possession of empty gourds or small boxes stuck up for its reception in almost every village and farm in America, and several of the American wrens will also build in cigar boxes, with a small hole cut in them, if placed in a suitable situation. The orchard oriole of the United States offers us an excellent example of a bird which modifies his nest according to circumstances. When it is built among firm and stiff branches it is very shallow, but when, as is often the case, it is suspended from the slender twigs of the weeping willow, it is made much deeper, so that when swayed about violently by the wind the young may not tumble out. It has been observed also that the nests built in the warm Southern states are much slighter and more porous in texture than those in the colder regions of the north. Our own house-sparrow equally well adapts himself to circumstances. When he builds in trees, as he no doubt always did originally, he constructs a well-made domed nest, perfectly fitted to protect his young ones; but when he can find a convenient hole in a building or among thatch, or in any well-sheltered place, he takes much less trouble, and forms a very loosely-built nest.

A curious example of a recent change of habits has occurred in Jamaica. Previous to 1854 the palm swift (*Tachornis phainopeba*) inhabited exclusively the palm-trees in two districts in the island. A colony then established themselves in two cocoa-nut palms in Spanish Town, and remained there till 1857, when one tree was blown down, and the other stripped of its foliage. Instead of now seeking out other palm-trees, the swifts drove out the swallows who built in the piazza of the House of Assembly, and took possession of it, building their nests on the tops of the end walls and at the angles formed by the beams and joists, a place which they continue to occupy in considerable numbers. It is remarked that here they form their nest with much less elaboration than when built in the palms, probably from being less exposed.

A fair consideration of all these facts will, I think, fully support the statement with which I commenced this article, and show that the mental faculties exhibited by birds in the construction of their nests are the same in kind as those manifested by mankind in the formation of their dwellings. These are essentially imitation, and a slow and partial adaptation to new conditions. To compare the work of birds with the highest manifestations of human art and science is totally beside the question. I do not maintain that birds are gifted with reasoning faculties at all approaching in variety and extent to those of man. I simply hold that the phenomena presented by their mode of building their nests, when fairly compared with those exhibited by the great mass of mankind in building their houses, indicate no essential difference in the kind or nature of the mental faculties employed. If instinct means anything, it means the capacity to perform some complex act without teaching or experience. It implies innate ideas of a very definite kind, and, if established, would overthrow Mr. Mill's sensationalism and all the modern philosophy of experience. That the existence of true instinct may be established in other ways is not improbable, but in the particular case of birds' nests, which is usually considered one of its strongholds, I cannot find a particle of evidence to show the existence of anything beyond those lower reasoning powers which animals are universally admitted to possess.—*Intellectual Observer*.

ABSTRACTS OF RECENT ACTS ON THE RELATIONS OF MASTERS AND SERVANTS.

An Act to establish equitable councils of conciliation to adjust differences between masters and workmen—

Gives (1) Power to her Majesty or Secretary of State to license councils of conciliation. (2) Councils to consist of not less than two nor more than ten masters and workmen, and a chairman. (3) Petitioners for council to elect first council.

(4) The council shall have power to hear and determine all questions of dispute and difference between masters and workmen, as set forth in the Act of the fifth year of King George IV., chapter 96, which may be submitted to them by both parties, and shall have, hold, and exercise all the powers and authority granted to arbitrators and referees. And any award the said equitable councils of conciliation and arbitration may make in any case of dispute or difference submitted to them shall be final and conclusive between the parties to such arbitration, without being subject to review or challenge by any court or authority whatsoever; and the said council are hereby further authorized to adjudicate upon and determine any other case of dispute or difference submitted to them by the mutual consent of master and workman or masters and workmen. But nothing in this Act contained shall authorize the said council to establish a rate of wages or price of labour or workmanship at which the workman shall in future be paid.

(7) No counsel, solicitors, or attorneys to be allowed to attend on any hear-

ing before the council or the committee of conciliation, unless consented to by both parties.

(9) Housholders and part occupiers may demand to be registered, and have a vote for the council, and may be elected thereto; but the masters shall appoint their own portion of the council, and the workmen elect their portion of the council.

The Master and Servant Act—

(4) Declares that whosoever the employer or employed shall neglect or refuse to fulfil any contract of service, or the employed shall neglect or refuse to enter or commence his service according to the contract, or shall absent himself from his service, or wherever any question, difference, or dispute shall arise as to the rights or liabilities of either of the parties, or touching any misusage, misdemeanour, misconduct, ill-treatment, or injury to the person or property of either of the parties under any contract of service, the party feeling aggrieved may lay an information or complaint in writing before a justice, magistrate, or sheriff, setting forth the grounds of complaint and the amount of compensation, damage, or other remedy claimed for the breach or non-performance of such contract; and upon such information being laid, the justice shall issue, or cause to be issued, a summons or citation to the party so complained against.

(5) The time to be appointed in the summons or citation for the appearance of the party complained against shall not be less than two or more than eight days from the date of the summons or citation.

(7) On neglect or refusal to obey summons or citation, warrant to issue.

(9) Upon the hearing of any information or complaint under the provisions of this Act, two justices, or the magistrates or sheriff, after due examination, by an order in writing under their respective hands, in their or his discretion, as the justice of the case requires, either shall make an abatement of the whole or part of any wages then already due to the employed, or else shall direct the fulfilment of the contract of service, with a direction of the party complained against to find forthwith good and sufficient security, by recognizance or bond, with or without sureties, to the satisfaction of a justice, magistrate, or sheriff, for the fulfilment of such contract, or else shall annul the contract, discharging the parties from the same, and apportioning the amount of wages due up to the completed period of such contract, or else, where no amount of compensation or damage can be assessed, or where pecuniary compensation will not in the opinion of the justices, magistrate, or sheriff, meet the circumstances of the case, shall impose a fine upon the party complained against, not exceeding in amount the sum of £20, or else shall assess and determine the amount of compensation or damage, together with the costs, to be made to the party complaining, inclusive of the amount of any wages abated, and direct the same to be paid accordingly; and if the order shall direct the fulfilment of the contract, and direct the party complained against to find good and sufficient security as aforesaid, and the party complained against neglect or refuse to comply with such order, a justice, magistrate, or sheriff may, if he shall think fit, by warrant under his hand, commit such party to the common gaol or house of correction within his jurisdiction, there to be confined and kept until he shall so find security, but nevertheless so that the term of imprisonment, whether under one or several successive committals, shall not exceed in the whole the period of three months: provided always, that the two justices, magistrate, or sheriff may, if they or he think fit, assess and determine the amount of compensation or damage to be paid to the party complaining, and direct the same to be paid, whether the contract is ordered by them or him to be annulled or not, or, in addition to the annulling of the contract of service and discharge of the parties from the same, may, if they or he think fit, impose the fine as hereinbefore authorized, but they or he shall not under the powers of this Act be authorized to annul, nor shall any provisions of this Act have the effect of annulling, any indenture or contract of apprenticeship that they or he might not have annulled or that would not have been annulled if this Act had not been passed.

(18) Nothing in this Act shall prevent employer or employed from enforcing their respective civil rights and remedies for any breach or non-performance of the contract of service by any action or suit in the ordinary courts of law or equity in any case where proceedings are not instituted under this Act; nor shall anything in this Act affect the provisions of the Act of the fifth year of King George IV., chapter 96, "to consolidate and amend the laws relative to the arbitration of disputes between masters and workmen," or of any Act extending or amending the same.

(26) This Act shall continue in force until the expiration of one year after the passing thereof (Aug. 20, 1867), and to the end of the then next session of Parliament, and no longer.

SELECTIONS OF ROSES FOR THE AUTUMN OF 1867.

A selection of the best roses, new and old, exclusive of those for the current season, arranged according to colours.

NOTE.—The varieties marked with an asterisk are suitable for cultivation in the neighbourhood of towns.

Abbreviations.—H. P., Hybrid Perpetual; B., Bourbon; B. P., Bourbon Perpetual; N. P., Noisette Perpetual; N., Noisette; C., China; T., Tea.

VERY DARK, in various shades—Purple, Blackish Crimson, Dark Crimson to Crimson Scarlet exclusive.

H. P.
Black Prince (W. Paul)
*Charles Lefebvre
Claude Million
Charles Wood
Dr. Lindley (W. Paul)
Gabriel de Peyronny
*Maréchal Suohet (Guillot)
Maréchal Vaillant
Mons. Boncenne
*Pierre Notting

*President Mas
*Prince C. de Rohan
Souvenir de Wm. Wood
*Vicomte Vigier
Xavier Olibo

B.
*Dupetit Thouars

THE BEST YELLOW ROSES.

There has been no addition to this class worth recording since the introduction of Maréchal Niel. The list, therefore, will be much the same as last year, and will be found chiefly among the Teas and Noisettes.

TEAS.—Gloire de Dijon, the long shoots of this should be stopped back, when almost every lateral will flower; Elise Sauvage, La Boule d'Or, Madame William, Madame Falcot, Vicomtesse de Cazès.

NOISETTES.—Celine Forrestier or Lysias, Jaune Desprez, Maréchal Niel, Narcisse, Smith's Yellow (under glass), Solfaterre, Triomphe de Rennes.

AUSTRIAN BRIERS.—Harrisonii and Persian Yellow, Yellow Provence.

TWELVE BEST TEAS FOR THE GREENHOUSE, OR OUT OF DOORS WITH WINTER PROTECTION.—Alba Rosea, Devoniensis, Gloire de Dijon, Madame Bravy or Sertot, Madame Falcot, Melanie Villermoz, Nipheto, President, Souvenir d'Elise, Souvenir d'un Ami, Triomphe de Guillot Fils, Vicomtesse de Cazès.

TWENTY PERPETUALS SUITED FOR PILLARS.—H. P.: Duchesse de Morny, Glory of Waltham (W. Paul), Lafontaine, Madame de Cambacérés, Jules Margottin, Jacqueminot, Triomphe des Beaux Arts, Mrs. Rivers, Madame Souppert. Teas: Gloire de Dijon, Climbing Devoniensis, Homère, Comtesse Ouvaroff, Bourbon, Paxton, Noisettes: Aimé Vibert, Seandens, Jaune Desprez, Jeanne d'Arc, La Biche, La Marque, Solfaterre.

TWENTY FINE ROSES FOR POT-CULTURE.—Alphonse Belin, Achille Gonod, Admiral Nelson, Beauty of Waltham, Catherine Guillot, Charles Lefebvre, Elizabeth Vigneron, François Lacharme, General Jacqueminot, Jules Margottin, Lælia or L. Peyronny, Le Rhône, Madame Alfred de Rougemont, Madame C. Wood, Madame Rivers, Maréchal Vaillant, Mrs. W. Paul, Modèle de Perfection, Princess of Wales, Victor Verdier.

It may be further noted that all the teas are suited for pot cultivation, and that "Malmaison" and Mrs. Bosanquet are two of the most continuous bloomers in pots, even in windows, that can be found.

Clapton.

W. D. PRIOR.

BEE-PROOF.—In a communication received by the Asiatic Society of Bengal, and published in its "Proceedings," Mr. Horne puts the question, "To what is due the exemption that some men have from the attacks of bees and wasps? One reads of it in England, and here is another illustration. Yesterday we arrived at our camp at Soj, when an elephant disturbed a swarm of bees in a tree. Immediately there was a cry in the camp, 'The bees! the bees!' and every one was running away, beating off the bees, which attacked every living thing within seventy or eighty yards. But it was strange to see one of the men, a gardener; he lay sleeping, with only a waist-cloth on, and nearly all his body exposed, under the very tree, yet no bee touched him! This man takes a bees' or wasps' nest, brushes off the bees or wasps with his hand; none sting him. He could on this occasion have made no preparation. Why is it? The bees, after about two hours, retired to their tree, and the camp was uninhabited."

STORING THE ROOT CROPS OF THE KITCHEN GARDEN.

This is a subject that has received such little attention from modern pens, that one would think it beneath their notice. But surely if they can tell people how to grow root-crops, it would in no way be lowering their dignity to endeavour to show them how to preserve them. At all events, this is what I propose to do, as I consider it a subject too much neglected by many, and very little understood by still many more, to whose interest it would be to secure the produce of the kitchen

loud are the complaints which sometimes reach us, that an inexperienced person would think that the root crops formed the staple commodity from which the proprietor's table was supplied during winter; and yet all this anxiety and lamentation concerns certain subjects which in all probability will be half thrown upon the rubbish heap before they are consumed, simply because people will not take the trouble to make themselves acquainted with the conditions under which they should be stowed away, and because they have not a suitable structure in which to keep them. For the latter there may be some excuse, but there can be none for those whose only anxiety

STOREHOUSE FOR ROOTS, &c. (Fig. 1.)

garden in a more satisfactory manner than generally prevails. I shall, therefore, deal with it at some length, and I hope my humble efforts will at least be the means of awakening attention to the conditions under which root crops should be stored for future consumption, for there is almost everywhere required a better provision for storing roots for winter use.

To say that half of the produce of root crops which are grown in the kitchen garden are usually spoilt will be speaking quite within bounds. To me this is such an evident piece of mismanagement—or, if you like it better, I will say a serious oversight—that I can only wonder why people express so much

about the crop is felt when it is growing. Surely, if such crops as parsnips, carrots, potatoes, &c., are worth growing, they are also worth stowing, and in such a structure as will be likely not only to keep them in good condition, but also to prolong their season of use. So great is the want of proper store-rooms in many gardens, that I have thought it requisite to furnish the printer with some sketches of the sort of store-houses required for the purpose, and I think those shown will, in one or other of the forms, meet the wants of all our readers, and the sections here given will render the remarks I have to make in my next paper more intelligible.

STOREHOUSE FOR ROOTS, &c. (Fig. 2.)

anxiety and spend so much time and labour in cultivating them, when they are conscious of the fact that they will half rot either in some damp hole called a cellar, or get frozen in some out-of-the-way place designated a loft. But nevertheless we so often hear complaints when things go a little wrong with a crop of onions or beetroots or potatoes, that if we had not constantly observed the want of a proper place in which to store them, we might be forgiven for believing that these crops were really valued and cared for in a proper manner, even after they were taken out of the ground. Indeed, so

Figure 1 is a section of a lean-to store-room designed specially for small gardens, or for those places where it cannot be sunk below the level. It is represented as being hidden by shrubs and trees on both sides; indeed, this would be necessary to exclude frost unless the walls were of unusual thickness. If thickly belted on both sides by evergreen shrubs, and the roots covered over during very severe weather with straw or brakes, very little harm would come to them, even if only a fourteen-inch wall at back and nine in front were used; and as a northern aspect may be adopted for

these buildings, there are but a very few places but can furnish a back wall already for such a purpose. In general construction these buildings are pretty much alike, that is to say, brick or stone walls and tiled roofs are essential, and as the different kinds of roots should be kept separate, they should be placed on shelves which should be of oak; the shelves are shown upon the sections in each case where they are in use. The bottom shelf should be kept about three inches above the floor, otherwise it will soon rot; potatoes may go on the bottom shelf, carrots, beetroot, &c., on the next, and the onions on the top. In every case means should be secured of admitting a current of air through the building; this may be done either with a small ventilator in the front

are considered unsightly, they are easily hidden by means of small shrubs or ivy.

Figure 3 is on a smaller scale than the above; but, nevertheless, a well-arranged and suitable structure, and such as would serve the purpose of many good gardens now wholly deficient of such a building.

Figure 4 is an improvement on the old-fashioned potato clamp. D is a small raised mound of earth, over which some straw is placed. This mound serves to drain the principal part of the clamp. The potatoes occupy the space E, over which is a layer of straw. F is a vacant space beneath a rough thatched roof carried to one centre pole, and above the potatoes. With an inlet for air in mild weather at about two

STOREHOUSE FOR ROOTS, &c. (Fig. 3.)

wall or in the door, but taking care that it can be closed at pleasure. With a similar opening at the apex, a continual current of air may be kept up, which will render the atmosphere of the place as sweet and pure as the nature of the subjects which it contains will admit.

Figure 2, if worked out, would make an admirable structure for such a purpose, and may be made capable of holding any quantity of produce. It should be sunk three feet below the level of the surrounding ground, and if in an exposed situation a bank of earth should be thrown up on each side. When this is done the internal air cannot be affected by any amount of frost. When such structures are built for this purpose, it is important to remember that drainage is necessary, as any accumulation of damp either in the house or under the floor will to a great degree render the air of the place unsuitable for the purposes for which it was intended. To guard against this I have shown (see letter A on the plan) the drainage under the floor, the water from this is taken away by a drain (B) to what we call here in the west a "dry cesspool;" that is, a hole of the size required is taken out, and in the place of the earth old brick heads

places round the bottom, and with an outlet at the apex, a small current of air may be kept up to carry off the foul air which is always generated where there is collected a mass of vegetable matter, and this open space between admits of its being carried off most effectually, while the inner covering of straw and the thatched roof are a safeguard against frost. Of other matters relating to this subject I must beg the reader to wait until another number. J. C. CLARKE.

BE CONTENT WITH WHAT YOU CAN DO.—I am not going to tell you that you can cultivate hothouse plants on a sunny border. I am not going to excite your imagination by assuring you that, under some next to impossible circumstance, *Stephanotis floribunda* may be grown without the help of a stove; but I am going to tell you that *clematis* will do just as well. What do you want? Flowers, you reply. Well, cultivate carefully such as will grow in your garden, and are suited to your soil and situation. There is nothing but folly in people of moderate means, or with other things to do with their money, breaking their hearts after *poinsettia* when *Virginian creeper* is the thing for them. You want flowers and beauty, plenty of both; yes, plenty, for the charm of plenty, the blessing of bounteous nature, cannot be described—must be felt to be comprehended and valued properly. But there are two friends necessary for success, mother earth and common sense. Of course you possess the last, so we need only discuss the first. It

IMPROVED POTATO CLAMP. (Fig. 4.)

or coarse stones are used. Into this the water is conducted, and soaks away between the stones or bricks. This is a very simple way of getting rid of water collected so far below the level, and answers every purpose for these kinds of buildings, and as the cesspool can be made within a few feet of the store-room, it does not entail any great amount of labour in moving earth to drain it effectually. Two shelves are shown on each side of the door which reach up to the ground-level. These are supposed to be for potatoes, while those above are for beetroots, carrots, &c. This, as well as figure 3, must be entered by steps inside the house, taking care to attend to ventilation as above advised. If the banks of earth

may be done shortly. A garden may be of any size, from a mignonette box to landed property; and the changes of soil from hungry to fertilizing may be done in a season if you have the power of procuring manure. If not—and farmers are often bound by their leases not to sell manure, and you may not be able to get stable soil easily—the process of improving your ground will be slower. There was an opinion once, and it was very cleverly advocated, that mere labour would improve the soil without any addition. The idea was that industrious digging between growing crops, and when they were out of the ground, would let in sun, air, and rain, and that with them would come all that the earth needed; and that earth pulverized and subjected to the action of such agents would be suited to a succession of crops, the refuse only of those crops being given to the soil. There is much practical wisdom in this when applied to the garden, where, with proper regard to the roots of the plants, the foil, as a general rule, can hardly be moved too much.—*London Society.*

YRINGA JOSIKÆA, A NEW HARDY FLOWERING TREE.

Delightful both to eye and the scent as the lilac is, and doubly charming from the early period when it comes into flower, it is scarcely what we should call a perfect shrub. Its straggling habit, its multitude of small branches, and its shiny thin leaves, combined with the considerable infusion of blue in the hue of the flowers, all give it something of a cold blue-nosed aspect, which to our mind detracts from its other charms.

All these characters have no doubt been more or less modified by cultivation, and better varieties, with a closer habit and greater warmth in the colouring, have taken the place of those less eligible; still, the original sin remains—more or less of a cold blueness subsists in even the best-coloured lilacs of the common species.

In strolling through an old-fashioned garden the other day, we were therefore agreeably surprised by stumbling upon a lilac with flowers of a depth of redness of colouring which surpassed anything we remembered to have seen. At a glance we saw that it was of a different species from the common one—the leaves were differently shaped, of a darker colour, and of a less glossy texture. The flowers were small and sparingly distributed compared with the immense trusses of flower which modern varieties of the common lilac usually bear; but the depth of the colour, which has a great deal more red and less blue in it than the other, makes it so much more effective that we preferred its sparing flowers to the rich masses of flower of the common kind. Perhaps the pleasure of change might go for something in our preference, but we have said enough, we trust, to make the reader think it probable that on one ground or other he might like it as well as we did.

The accompanying wood-cut, taken from a rough sketch, shows the appearance of the flower. At first we had no recollection of the species—it is so long since we saw it—but by and by our memory went back, and brought to mind a species which was rather a favourite some thirty years ago, which answered pretty well to this one, and which on examination proved to be it.

It was discovered in the Siebenburgen (we presume the mountains on the Rhine so named) by a lady—the Frau Baronin von Josika, after whom it was named *Syringa Josikæa* by Baron Jacquin, who exhibited it and described it at a scientific meeting in Hamburg in 1830. It was next noticed in the *Botanische Zeitung* for 1831, and living specimens of the plant having been obtained, it was sent by Messrs. Booth (the eminent nurserymen of Hamburg) to Dr. Graham, the then Professor of Botany in Edinburgh, who figured and described it in the *Botanical Magazine* in 1833. It was also figured in the *Botanical Register* and other botanical or horticultural publications of the day.

The occurrence of a distinct species of *Syringa* in the mountains of the Rhine has a wider significance than at first would appear to attach to it. It has a bearing upon the disputed place of origin of the common lilac. Persia is usually taken for granted to have been the place of its nativity, and Decandolle, in his *Géographie Botanique*, specifies it as one of those species which have by naturalization, and spreading from gardens and cultivation, given rise to what he considers the unfounded supposition that it was a native of Europe. On the other hand, there is strong evidence of its occurrence in Europe in places where it can hardly be supposed to have been introduced either by man or any of the other usual agents of dispersion. Dr. Heuffel (*Bot. Zeitung*, 1831) states that it adorns with its copious blossoms the inaccessible chalky precipices of the Coerna Valley and Mount Domaglet, in Hungary, as well as the whole group of rocks along the Danube, at the military boundaries of Moldowa, Szasz, Csiklova, and Krassova. But no stronger proof could be wished than the actual occurrence in Europe of an allied species, which is not present in Persia or anywhere else. Such is the *Syringa Josikæa*. It is perfectly hardy, and flowers in the open border simultaneously with the common species—that is, in May and June. If gardeners would bestow the same attention on this species which they have upon the common one, we can see no reason to doubt that they would obtain varieties with as large trusses of bloom (if that be desirable) as they have done with the *Syringa vulgaris*.—M., in the Farmer.

SYRINGA JOSIKÆA (Natural Size).

PRACTICAL NOTES ON STRAWBERRIES.

The strawberry is perhaps more than any other fruit a universal favourite. I cannot remember any one saying, when presented with ripe strawberries, that they were repulsive or distasteful. So, more or less, we are all interested in strawberries, and I need no more preface to these practical notes. In my desire to say anything respecting their cultivation, it may be assumed by some that I am only traversing an already beaten track. This is correct to some extent, but it must be borne in mind that the different writers who have preceded me have in many instances spoken or written of their practice from opposite directions of the three kingdoms. We have therefore to consider the respective influences of climate, soil, and surroundings apart from the mere routine of culture. In an area so restricted as Britain there is as much variation in the extreme points of the island in regard to the temperature as there would be in the atmosphere of a stove and greenhouse at one and the same season of the year. To this, then, we attribute the presence in the markets and fruiterers' shops of quantities of ripe fruits the produce of plantations in the open ground, and this several days before they are ripe in the majority of private gardens, especially in the metropolis. In this, as in many other instances pertaining to the earliness of fruits and vegetables, these results are often beyond the cultivator's control, owing to

influences which he can neither obtain nor remove, they being peculiar to the spot, and in no respect the result of his skill. As an illustration of my argument, I would say, that when filling the situation of gardener to a gentleman in the county of Kent, part of my charge consisted of a very large kitchen garden. Adjoining this was a cultivated field of about ten acres in extent. This was annually sown with early peas to be gathered for supplying the London markets. In the gardens I would sow the same variety of pea at the same period they were sown in the field; yet, strange as it may appear, the earliest gathered were the peas grown in the field. Why this should be I cannot say, further than to suppose that the open space was more subject to the beneficial influence of favourable weather, and enjoyed a larger total of sunlight as compared with the crops grown in the garden; the latter being retarded in their earliness in a degree by the closeness of the surrounding objects, such as fences, trees, &c., which some would suppose would rather hasten than otherwise. But my inference was that they only tend to encourage weak, or perhaps luxuriant, instead of a short sturdy growth. Now this is just the case with early out-door crops of strawberries. Quantities of them are gathered from plantations which are made on the slopes and banks in the open spaces of many of the market grounds of Kent. The soil, especially in the neighbourhood of Erith, is very stony, and the care with which the cultivators cover the surface assists much to maintain a genial moisture to their roots, and at the same time absorb the heat of the sun. This, then, quickens their early ripening; but it is not alone from this source that the early fruit is supplied. The mode of convey-

ing them into the London markets is very different now to what it was twenty years ago and previous to that period. You would on fine summer mornings see numbers of women following each other from Isleworth, Deptford, and other localities in the neighbourhood of London, with large round baskets on their heads packed with pottles of this delicious fruit. But the progress of time has afforded us a quicker transit; so that fruit gathered at the same period of the day, perhaps in the western or southern parts of England, will arrive in the market as early in the morning as that grown only a short distance from town.

At this season, as other kinds of crops are being cleared from the ground, their places may be occupied with fresh plantations of strawberries. It is certainly not too late to plant strawberries, but if planted earlier they will be the better prepared for producing good fruit next season. However, following an oft-repeated maxim, "better late than never," we would presume that, finding you had not space at your command earlier, you have planted your runners in nursery beds, so that you could take them up with a trowel, and in that case the effects of the change would be very slight. Or, better still, that you have layered or pegged your runners into pots, and that now you have well-established plants, exactly in the way you would prepare them for forcing, with this exception, that they are either in large 60 or 48 sized pots instead of 32 or 6-inch pots. If you have not plants so treated, then my advice is, purchase them of some respectable nurseryman who has them so prepared. Well, the next thing to consider is the best situation in the garden for the varieties you may plant. Of course your selection of sorts

A YOUNGSTER, hearing his mother remark that she was fond of music, roared, "Then why don't you buy me a drum?"

will depend on the extent of ground at your disposal. The varieties advertised at the present time are about fifty in number, and probably they all have some sort of merit. But as no one requires so many, except it be to form a collection, I shall here name only a few, which I can recommend as good for almost any soil and climate, viz. :—

BLACK PRINCE.
PRINCESS ALICE MAUDE.
KEEN'S SEEDLING.
SIR HARRY.
SIR CHARLES NAPIER.
BRITISH QUEEN.

The first on the list, *Black Prince*, is to be valued more for its earliness than for any other quality it may possess. As the berries generally are small, though produced in abundance, the best plan for obtaining large fruit is to grow them only one season, making fresh beds every year. If you are cramped for space, I should not grow many plants of them, as the other superior sorts, such as Keen's Seedling, quickly succeed it. If you have a wall or fence with a south aspect, and a border running alongside of it, then, in order to economize space and obtain very early fruit, adopt the following method: Plant a row the whole length of the wall or fence, and within (say) six inches of it. With this plan I have been very successful in obtaining early ripe fruit before the main crops were ready. This is about the best use you can make of *Black Prince*. As soon as they have ceased to yield good fruit, and you have obtained your runners for the following season, destroy them. In preparing your ground for planting, deep trenching is essential for the well-doing of all the kinds, as the roots descend a great depth, and the deeper you deposit manure, or any other kind of vegetable refuse, so much the better, as the roots are sure to find the desired nourishment. The strawberry thrives best in a mellow loam which is not of a clayey texture. Of course we must in most circumstances do the best with what soil we possess, whether it be the most suitable or otherwise. The best aspect or situation for early beds is decidedly a south border; the wider the border the better, so that a narrow pathway can intervene between it and the wall; but for general crops open plots are decidedly preferable.

Princess Alice Maude.—This is not so generally cultivated as it deserves. As an early strawberry it is invaluable. Those who grow for sale quite understand that, but gentlemen's gardeners seem to overlook its merits. It certainly does not possess the flavour of a Keen's Seedling, but, as a cropper, it is more to be depended on, being very prolific. It produces nice medium but even-sized berries, and the colour is a very rich crimson. This is the variety that is so much admired when displayed in the windows of the fruiterers' shops at the commencement of the strawberry season. It is also a more compact grower than Keen's Seedling, not requiring the room the other does for its growth, which makes it invaluable for small gardens.

Keen's Seedling, like the *Black Hamburgh Grape*, is a very popular and useful variety, and a delicious flavour when fully ripe. But in some soils great numbers of the plants will in some seasons become barren, although they have previously grown very luxuriantly. This is a sad disappointment to cultivators of limited means; but where the soil and situation are suitable to its growth, it is one of the best among the oldest of the principal varieties grown.

Sir Harry.—This with me has proved a very hardy and very useful strawberry for general purposes, being very prolific and of good size, but it requires a warm situation in order to ripen it thoroughly, otherwise the flavour is acid; but when fully ripe, the berry assumes a very dark colour; and the flavour is excellent; with me it has never failed as regards a crop.

Sir Charles Napier.—This variety thrives in almost any situation; its growth is compact, its fruit is cone-shaped, and in colour a bright scarlet, which gives it a very handsome appearance when dished. The flavour is rather acid, but it is a certain and prolific bearer in almost every locality, and large quantities of it are forced throughout the country for market as well as private use, for which it is exceedingly well adapted, and also for preserving.

British Queen.—The merits of this strawberry are universally acknowledged throughout the United Kingdom; therefore it may be considered superfluous for me to offer any observations respecting its general habit. However, I cannot refrain, as I have witnessed it growing and fruiting first-rate in some gardens, and in others the reverse of it. The *British Queen* may be justly styled *The Queen* of all strawberries in respect of flavour; and there may be exceptions in which it is surpassed in size, but they are but few. The best plot I ever saw of this excellent strawberry was that cultivated by Mr. George Taylor, gardener to Miss Williams, of Stamford Hill,—a name associated with the production of some of the best collections of single blooms of *Chrysanthemums* that were ever exhibited in this country. I have had an opportunity for several years past of watching his mode of culture. His method has always been to have two beds of this favourite variety under cultivation, so that when a bed had been planted two years, and finished yielding its crops in succession, the same would be destroyed, and replaced by young plants. But previous to doing so, the ground would undergo the process of deep trenching and manuring. The plants intended for the bed were the strongest and earliest runners he could obtain; these were layered in pots of soil, and when sufficiently rooted were detached from the parent plant and kept watered, and otherwise properly attended to till the bed was ready for their reception. The produce of his beds the first year of their being planted was extraordinary both in quantity, size, beauty, colour; and I think, if I rightly remember, his method was to plant two plants together, so that if one did not succeed the other would, and in the event of both succeeding, of course it would be a double advantage. There is one circumstance in this cultivator's favour, which greatly aids his practice, and tends to preserve this tenderest of all the strawberries in regard to constitution, and also assists to retain the warmth in the soil when most needed, by keeping it naturally drained, namely, that the subsoil of his garden is composed of nearly all gravel. To local influences are many of us, then, indebted for our success, though frequently perhaps unconscious of the fact.

The distance apart which strawberries should be planted must be determined by the length of time they are to remain in the same spot. If only for one year, you would not plant them so far apart, because their growth would not need the space; the greater the width you can afford them from row to row, the more beneficial will it be in quickening the production and ripening of the fruit.

JNO. F. McELROY.

Calendar.

WORK FOR WEEK COMMENCING OCTOBER 12.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—Ground intended to be drained should be drained now, that benefit may be derived from the improvement at once. Wherever *Equisetum* or rushes grow, the cultivator may be sure there is need for drainage, and that the work will soon pay for itself in increased production. This is a better time than that usually adopted for sowing speculative crops. On lands that lie high and dry, sow *Mazagan* beans, and *Ringleader* and *Daniel O'Rourke* peas. Lay down *broccolis* with their heads to the north. Keep plots of cabbago filled by transplanting. Take up carrots, and store only the sound roots, and those to be stored dry. Potatoes are never good if stored in the damp; better give them all away than store them, as some people do, to sodden in wet, which renders them unpalatable and unwholesome. Plant chives, which never fail to furnish an onion flavouring for soups.

Flower Garden.

SPRING FLOWERS.—The following are all exquisitely beautiful, and if not in the possession of the cultivator should be secured at once. Any of the species of perennial Iberis, the flowers of which are snow-white, and magnificent in large tufts on rockwork. *Aubretia purpurea* and *grandiflora*, and *Alyssum saxatile*: showy yellow, impatient of wet, quite hardy elevated on rockwork, and worth growing in pots. *Arabis alpina*. Italian *Coltsfoot*; useful to cover banks, for the sake of its perfume in February; it will flourish in the darkest of town gardens in a mixture of good loam and chalk. *Double Wallflowers*: we only grow two varieties now—the tall double yellow and the dwarf double yellow; and we generally have a lot of each potted to perfume the sitting-room; they should be taken up now and potted, and put in a pit. *Hepaticas*, *Primroses*, *Polyanthuses*, and *Violets* must have a place amongst the best of spring flowers—in fact, the garden will be dreary without them. Of bulbs, secure and plant a good assortment of *Jonquils*, *Snowdrops*, *Crocuses*, *Narcissus*, early *Tulips*, *Hyacinths*, *Dog-tooth Violets*, &c.

CARNATIONS and PICOTEES not yet rooted from layers must be taken off the stools and planted under hand-glasses; those with a few root fibres may be potted; having begun to root, they will soon gain strength. Border cloves may be propagated to any extent from cuttings in spring.

CHRYSANTHEMUMS to have less manure water as they show colour, and to be discontinued (using plain water only) as soon as a few of the first flowers are open. Thin the flowers on plants from which blooms are to be cut. Large-flowering varieties out of doors are liable to suffer from high winds and drenching rains; give them some rough sort of shelter, to prevent the spoiling of the best blooms.

Fruit Garden and Orchard House.

STRAWBERRIES to fruit in pots and troughs ought now to have plump crowns and be quite at rest, the pots full of roots and free from worms. Now lay them on their sides on coal-ashes under a fence or wall, and by means of a few hurdles, or some other rough contrivance, shelter them from rain, and there leave them till taken in to force. Runners well rooted may be planted now in beds to bear next season. Plantations made at this late period should be of carefully sorted plants—the best only of the runners that have rooted farthest away from the parent stools, and these to be taken up with good balls, and planted in the beds directly.

UNFRUITFUL TREES may be improved by commencing at once to root-prune, manure, or drain the soil. The nature of the cure must depend upon the cause of barrenness. If the trees have attained a bearing age, and are over-luxuriant, root-prune by this simple method: Open the soil three parts round each tree, at a distance from the stem of from 2 to 3 feet, according to the size of the tree. The roots must be cut back to a general average of 2 or 2½ feet, except the part where the soil was not opened, where the roots will remain of course their original length. The roots cut back to be carefully laid out near the surface, and a little fresh soil used in filling in. Next season open the soil on the side left undisturbed the year before, and there cut the roots to 2 or 2½ feet, and so on annually or biennially, according to the growth the trees make. Old trees that have borne for many years and are getting weak, to have the surface-soil thinly pared off, and a layer of new soil laid down over the roots, and above that a layer of dung only slightly rotted. Trees suffering from wet at the roots, and on which there is moss and canker, require draining; and without draining they can never do much good.

Greenhouse and Conservatory.

ERICAS can be better wintered in a pit than in the greenhouse. It is certainly best to let them taste as little as possible of fire-heat, though they must be kept safe from frost. A damp still air, especially if a little warmed to suit the growth of soft-wooded plants, is most injurious to these nearly hardy and free-natured plants. Water only on fine days, and then as early as possible; keep the plants hardy, and if they get three or four degrees of frost on them, they will take no harm if kept dark till thawed. The result of such treatment will be short joints and a fine bloom.

VERBENAS and PETUNIAS from autumn cuttings are best kept with *Cinerarias* and *Primulas*, as the same treatment will serve for all, and they will require fumigating more frequently than other plants. All these things should be grown very slowly now, as the worst times for them are yet to come. Give plenty of air.

MIGNONETTE sown now in pots of rich light soil, started with a little bottom-heat, as on a bed of leaves or uraly worn-out dung, and kept in a pit all winter, will bloom early next spring, and a few may be forced. It requires but little skill indeed to flower *Mignonette* at any period of the year; but at this season one important caution must be given, and that is, to grow the winter stock in pots extra well drained, and never to wet the leaves of the plants.

Forcing Pit.

CUCUMBERS to fruit during winter will now be showing signs of fertility, in which they must not be too much encouraged, unless the plants are strong. If allowed to bear too early, they will soon cease to bear, and the fruit will be small and inferior. Keep them carefully trained; take the leaders up their full length before stopping, then stop every side-shoot at the second joint. Pinch off the young fruit till the plants are in a robust state, with plenty of large healthy leaves; if fit to begin bearing, thin the crop moderately. Encourage root action by top-dressing with a mixture of leaf-

THE ORNER OF THE DAY.—The writer of the letters in the *Times*, advocating "The cordon training of fruit-trees" as adopted in France, is to be decorated for his pains—he is to receive the Grand Cordon of the Legion of Honour.

—Punch.

mould and rotten dung. The usual advice to set the blossoms we consider fallacious; there will be just as good a crop without any such waste of time.

VINES.—Where fruit is to hang some time, all decaying berries must be cut out from time to time, and the atmosphere kept dry. Cut away all the sappy and softer ends of the rods, without respect to the system of pruning adopted; this will cause the remaining buds on the rods to swell nicely, and promote their ripening. Vines that are indisposed to go to rest may be assisted by a removal of their leaves, and getting the border as dry as possible.

PINES to have less moisture both to fruiting and growing plants. Give air every day if possible, and keep the beds in a sweet and sound condition. Fruits ripening should have a temperature of 60° at night; day temperature to depend on the amount of light; on dull days 70°, bright days 80°.

WINTER MUSHROOMS.—Large beds, well made, keep such a genial heat that, with good manure and good spawn, success is pretty certain. Small beds cool quickly, and in small places the grower is often obliged to use manure that has become too much fermented, and so his best efforts are in vain. The best prospect of success is where a man can select the manure as it comes from the stable, or, better still, in the stable itself, and the mushrooms ought to be grown in a house adjoining the stable, if possible, or, if there is plenty of room, it may actually be done amongst the horses, and the heat of their bodies will do instead of hot-water pipes. We will endeavour briefly to advise how best to grow mushrooms on a small scale. The best way of all is in a dark, warm, unventilated shed, with a brick wall at the back. The droppings should be raked together in ridges, every day or two, until there are sufficient for a bed. While they are accumulating they should be turned over and drawn up in small heaps or ridges again, every two or three days, to prevent a rapid fermentation. When there are sufficient of these heaps to make a bed, wheel into the shed as much turfy sandy loam as will equal one-third the bulk of the manure, and mix all together, and allow the mixture to remain in one heap for two days, which will cause a gentle fermentation to commence. Provide for the bed some kind of support in front, such as rough boards or turf-sods; make the bed four feet wide, four feet high at the back next the wall, and sloping to two feet in the front. It must be in a condition of equable moisture throughout—neither wet nor dry—and in the process of making, it must be frequently beaten down to render it quite firm. A much-experienced cultivator would know to what temperature, within a degree or two, the bed would rise, and would probably insert the spawn the same day as the bed was made; but for a beginner the safer way is to wait a few days, and then insert a hotbed thermometer, to ascertain what is the heat inside the bed; if it is over or under 80° wait a day or two longer. By that time, if the heat has increased, all is well; you will have a good bed. If it has decreased, you will never get mushrooms, and the best way to proceed is to take it to pieces, mix with it a good fifth or fourth part of fresh droppings—you must always be collecting these, fresh and fresh, and keeping them under cover—and make up the bed as before. The heat will certainly rise now. When at between 70° and 80°, insert the spawn in pieces the size of hens' eggs, about six inches apart and three inches deep. We have known one piece of spawn as thick as a fist suffice for a bed five-and-twenty feet long, and many a good crop has been taken from beds that were never spawned artificially; for, when properly managed, the material itself is generally rich in spawn, which may be seen running through it in the form of gray filaments. When the spawning has been accomplished, spread over the bed two inches of nice clean sandy loam. If the place is warm and rather dry, cover the bed with some clean hay or straw; if the place is damp and cold, do not put on straw, but lay some rough boards over if you have them, supporting the boards on small flower-pots. If hay or straw get full of mildew, the flavour of the mushrooms is impaired. Never water a mushroom bed until you have seen fruit on it; then, if rather dry, water moderately with tepid water. We must endeavour now to suggest how to make one bed serve all the year round without any more spawning. In the usual way, as soon as one bed comes into bearing, another bed should be made to succeed it, and so on for ever. The first mushrooms ought to appear within six weeks, and the length of time the bed will bear will depend on the steadiness of the temperature in the soil and the surrounding atmosphere, and the supply of sufficient moisture. The bed at 60° to 70°, and the atmosphere of the shed at 50° to 65°, will be capital conditions for a profitable result. Now for the recipe to make one bed serve the whole year round, which will be useful to those who have only one suitable spot for a mushroom bed, and in fact can be carried out with such certainty that it is worth the while of any person fond of mushrooms to put up a shed for the purpose, with brick wall at back high enough to allow of head room within, a double roof, that is to say, rough battens, and thatch all over, with a space of air between, and double sides consisting of rough boards and a thick outside lining of furze, or other rough warm stuff, to promote snugness within. You have but to make up the bed as directed, using grass-sods in front instead of boards. Let it be, if possible, not less than 19 feet long, or any multiple of 19, as 38, &c., &c. But any length will do that is convenient, as the plan to be described admits of modifications. As soon as the bed is made, go on accumulating droppings as before, keeping them always under cover. When the fruiting of the bed is on the wane, dig out the stuff in trenches across the bed one foot wide and three feet apart. Suppose the bed to be nineteen feet long, the operation will result in trenches as shown in this section of thirteen feet length of the bed, on the scale of a quarter of an inch to one foot:—

The stuff taken out will be useful in the compost yard, for although the mushrooms extract the principal goodness from it, it will be found capital for fuchsias and flower-beds. If you have a dry warm place in which to store it for use, lay it up in long ridges, and you will get a few more mushrooms out of it. As for the trenches, fill them with a mixture prepared in the same way as the first; they will communicate heat to the bed, and the bed will communicate spawn to them, and the bearing will continue. In the course of a month or so, take out trenches again midway between the last and put in fresh mixture. In the course of another month take out trenches on either side of the last, and so go on removing and renewing, and you will always have mushrooms. There are many other ways of growing them. They may be grown on shelves in carefully-saved droppings without loam, and the beds on the shelves need be only twelve to eighteen inches deep. As they do not want light, the shelves may range one above the other from floor to roof. They may be grown in pots and boxes, in cellars and cupboards; but these make-shift methods are very inconvenient, very liable to failure, and apt to make a mess where cleanliness would be more appropriate. But the rationale of the growing is always the same, and it would be waste of space to multiply particulars. It must be borne

in mind that a certain degree of moisture and warmth are essential, that light is not essential, but they may be grown in full daylight as well as in the dark; but we prefer the dark, because an opaque roof is warmer than a glass one, and in winter we must husband warmth, or be at the expense of heating apparatus.

FORCING FRENCH BEANS.—French beans are generally grown in pots, and sometimes in boxes; but the best of all plans is to grow them in open beds, nicely warmed, and of sufficient extent to give a regular succession of produce. We will, however, first consider their cultivation in pots; and here, as in almost every other thing, gardeners differ in their practice—some obtaining fine crops in a very off-hand way, while others only attain the same object by a comparatively laborious and unnecessary process. These parties sow their beans in 4-inch pots, five or six beans in each pot, and when they have attained sufficient size shift them into the larger, or fruiting pot. For this purpose 11-inch pots are generally used; but for a crop in the depth of winter, if good soil is used, 8-inch pots will be found sufficiently large. The mode of procedure is this: Having drained the pots, place in the bottom of each a layer of good rotten dung, and then fill them two-thirds full with prepared compost. If the soil is warm, and your plants in a fit state, you may proceed to pot them at once, keeping the seed-leaves or cotyledons level with the rim of the pot; but if not, place the pots in the house until the soil gets warmed, and then you may proceed with the potting. The soil should be pretty dry at the time of using; but, if it is not, do not press it too firmly in the pots, as French beans like a free open soil, through which they can receive plenty of water, and yet not have it stagnant in the pots. When the soil in the pots gets full of roots, fill the remaining portion. This will be about the time the plants are in bloom, and will add very materially to the swelling of the produce. With beans in boxes much the same treatment is pursued as to draining, soiling, &c. Some persons use boxes of large size, nine to ten inches square; but boxes six to seven inches wide and deep, and three to five feet long, are the most convenient for general use, and, with a judicious supply of liquid manure, quite large enough for the purpose. A more expeditious plan is to take the full-sized pots or boxes, drain and fill them two-thirds full with manure and soil, and sow the beans at once where they are to stand, using plenty of seed, so that the strongest plants may be selected and the others destroyed. Another plan is to sow a quantity of beans thickly in a pot or box, and transplant them when of sufficient size; and this is not a bad plan. The treatment which the plants require is, first, that the temperature should not fall much below 55° during the night; neither is it desirable that it should much exceed 60°; therefore from 55° to 60° may be considered a suitable night temperature. Through the day, in dull weather, the heat may rise to 65° to 70°, and with the sun-heat to 80° or 90°, taking care to keep the atmosphere moist, and, except in the two darkest months, to syringe copiously both in the morning and evening. Some persons object to syringing while the plants are in bloom; but that is nonsense, for daily syringing will not interfere with a good crop of beans; but you frequently see the want of the syringe result in a troublesome crop of thrips or red spider. As the beans progress in growth, it sometimes happens that a part of the shoots will become spindly and long-jointed; should such be the case, stop them at once to the lowermost joint—indeed, an occasional regulating with the finger and thumb will add materially to the produce. Water, as we have remarked before, must be plentifully supplied, and weak manure water, especially while the crop is swelling. Ventilation cannot be too copious, either by night or day, so long as cold draughts are avoided; but it must be recollected French beans are scarcely more hardy than cucumbers, and therefore the air given must be regulated with caution. Should insects be likely to become troublesome, add some sulphur to the water you syringe with, and for thrips or fly some tobacco water; for, after all, these old-fashioned remedies are both cheaper and more certain in their effect than "Gishurst Compound," which is not to be trusted with tender-foliaged plants. From the preceding remarks, it will be perceived the chief requisite in the successful cultivation of the French bean as a forcing plant is a rich soil, brisk moist heat, and a free circulation of air. With these healthy foliage is a necessity, and free-growing plants are rarely much troubled with insects. On the score of soil it may be remarked, it should be fresh maiden loam. Sometimes the soil of cucumber or melon beds is used; but that is not to be recommended, as in it the plants get full of insects, possibly from ova deposited in the soil; neither do they grow so freely, as in some cases we have seen them refuse to grow in old soil at all, and in one particular instance crop after crop was tried with the same result. A friend of the writer's used to collect mole-hills, and mix the earth with old mushroom soil; indeed, two parts fresh loam and one part the dung of an old mushroom bed, is as good a mixture as can be used for growing this esculent.

Literature.

H. Cannell's *Extending and Pruning Method of Grape-growing*.—This is a short essay on the comparative merits of the vine to a rafter system, and the one vine to a house system. The essay finished, Mr. Cannell fills up the book (to make a shilling's worth in bulk) with reprints of the greater part of the correspondence that has taken place upon the subject. The book is therefore useful as a summary of the discussion, and worth much more than the price charged for it to all who are interested in this question. But we are bound to say that "H. Cannell's extending and pruning method" was known somewhat before H. Cannell had his tender gums rubbed by a tender nurse's fingers, somewhat, indeed, before the advent of such a prophet. We are indebted to Mr. Cannell for all the light he has thrown upon the subject of vine-growing, and more for the life he gave to the recent discussion; but we must object to the extension system being claimed by him as *his* method; there is a spice of shop in the proceeding that will displease all sober-minded people. As to the respective merits of the "rival systems," the vine to a rod system gives quick results, and has rendered so much good service that unreserved condemnation of it is unreserved nonsense. But there can be no question that when a house is occupied with one vine, the labour and anxiety of the cultivator are greatly lessened, the crop is more certain, and the quality of the crop is much better than young vines will afford.

Tall's *Patent Apparatus for Constructing Walls, Houses, &c.* J. Tall, Falstaff Yard, Kent Street, Southwark.—This is an important contribution to social science, and from it we may expect many advantages to arise in the economy of rural life, and especially in the improvement of artisans' and labourers' dwellings. The Tall system of building may be described in a few words. Portland cement is mixed with stones, sand, and other rough waste material, and while wet is formed into walls by pouring the mixture into moulds made of rough woodwork. By inserting a round core where

necessary, a flue for a fire or for ventilation is formed, and the flues are all round and smooth internally, so that smoking and taking fire are rendered next to impossible; or, at all events, if they do take fire, there can be nothing but soot to burn in them, for no bonding timber is used in any part of these buildings. Houses, sheds, and other structures, formed on Tall's plan, are cheaper, drier, and more lasting than the best work in brick. These houses are said to be eight or ten degrees warmer in winter than brick houses.

The *Intellectual Observer* for October contains a valuable paper by Mr. H. J. Slack, on the beautiful *Euplectella speciosa*, with a coloured plate; the story of the opening of old grave-mounds in Derbyshire, by Mr. Jewitt; an elaborate essay on shooting stars, by Mr. Proctor; and an analysis of the extraordinary hypothesis of Gruithuisen of a city in the moon, by the Rev. T. W. Webb. Amongst minor matters, occurs the following note on the action of green light on plants. M. L. Cailletet details experiments on the influence of different coloured rays, and the decomposition of carbonic acid by plants. He observes that green light afforded unexpected results, whether this colour was obtained from a glass, vegetable leaves, or solutions. Under its influence carbonic acid is never decomposed; a fresh quantity of gas seems, on the contrary, to be produced by the leaves. When a glass containing pure air and a leaf was placed in full sunlight, under a green glass shade, after a few hours a quantity of carbonic acid was obtained scarcely inferior to that which the leaf would have evolved in the dark. This experiment, he thinks, may explain the sickly condition of vegetation under large trees.

The *Floral World* for October contains papers on fruit-tree cultivation, the villa kitchen garden, the auricula, the improvement of the rosery, extensive grape-vines, and on the cultivation of various flowering bulbs.

Types from the Hebrew and Greek Scriptures as illustrated in the Colours of the Rainbow. By MRS. KELLY. Darton and Co.—The object of the authoress of this work is to explain and illustrate the symbolism of colours, in so far as may be needful for the purpose of rendering intelligible, or helping out the meaning, or adding to the force and beauty of such Scripture precepts, allusions, and figures, as are most directly associated with colours. For example, we read in the mosaic ritual of coloured curtains and coloured robes; if the colours were symbolical, it is but proper we should have, if attainable, a key to the symbols. Thus we at once and by this example merely justify the idea of illustrating the types of the Hebrew and Greek Scriptures, and the next business in this connexion is to ask how Mrs. Kelly has performed her self-imposed task. We are bound to say that this is by no means a good book. It contains much useful information, and may be found serviceable by many students of the Old Testament Scriptures, but it is too pretentious of learning, too lean in facts, too fervid in imaginary (very imaginary) spiritual interpretations of things quite carnal and commonplace, and everywhere there is such a straining after an indefinable effect, that we can only say of it that in tone and matter it is far below the requirements of the subject.

Correspondence.

ZONAL GERANIUMS AT THE MANCHESTER EXHIBITION [see pp. 383, 424].—I am obliged by your insertion of my letter, also for the *gentle reproof* you have given me. You are not, perhaps, aware that Mr. Watson makes it a practice of depreciating every other collection of plants in favour of his own, and that his manner is becoming very offensive, not only to exhibitors, but to visitors. It is all very well to do all the business one can at an exhibition, but it should be done in a legitimate way. I have always in my reports said all I could in praise of Mr. Watson's energy, but found, in return for it, he was using all his influence to depreciate my plants. It is all very well for you to expatiate upon the weakness you fancy I have displayed, but place yourself in my position, and I fancy you would be troubled with the same *weakness*. I certainly had removed some of my plants after the first day's show was over, and replaced them with others. This, I believe, is not unusual when an exhibition is continued so long as the late Manchester Exhibition was.

October 1st, 1867.

JOHN WILLS.

Mr. Wills had prepared me for an article in your excellent paper from his pen, as he had promised me what he terms a *little one* when at the Kensington show on the 17th of September, but I can assure you, Mr. Editor, that I was quite unprepared for the savage attack upon both myself and the two beautiful plants of which I am the fortunate raiser, for these are the real objects of his attack, although he hides behind the scenes. I am fully aware that Messrs. Wills and Co. have been long aiming to put the extinguisher on them; hence the feverish anxiety of certain parties to get up a show for the simple purpose. Blind indeed must be the individual who cannot see the bitter envy and jealousy existing in certain quarters; yet, in spite of their teeth, *Miss Watson* will sell by the hundred ere 1869 shall have passed away, when Mr. Wills's Florence will not sell by the dozen, and scarcely perhaps by the single plant. As for my plant of Sultan being a disgrace to his green cabbages, it is a *pity*; for truth is truth, and I say, without fear of contradiction, the bulk of the plants exhibited by Mr. Wills were little better than common zonales, and to exhibit them against variegated geraniums is little less than dishonest. As to Mr. Wills's "Florence," of which he says every one who saw it gave it the palm at the exhibition, I beg leave to say, if it is to be a first-class plant, he must get rid of two fatal faults: first, the colours run into each other, and have the appearance of having been in a *paint-pot*; and secondly, the green breaking through the zone, six plants out of seven doing so, as, for instance, the one exhibited at Kensington. And I must say, Mr. Editor, that if what Mr. Wills says be true, those persons were either short-sighted or left their judgment at home. As to the eight plants which took the second prize, I beg leave to say, Mr. Wills never saw cleaner-grown plants in his life; and if Mr. Wills would leave envy, prejudice, and self-interest at home, and not suffer them to becloud his vision, he would acknowledge the truth of this assertion. As to the varieties being too much alike, this is not my fault; we must blame Messrs. Wills and Co. for giving prizes and certificates to plants that are not better than others in cultivation, and no distinguishing mark to recognize them in the distance by a good judge, to the exclusion of those kinds which are distinct, and possess merits such as the prized and certificated kinds cannot boast of. In reference to Mr. Wills's puzzle, I can give him the little piece of information he appears so earnestly to crave in reference to Sultan. To the bar of public opinion the Sultan has been brought, and the result will be, many plants will be sold for growing in collections of variegates. Mr. Wills will, doubtless, have seen

my challenge to Messrs. Smith and Perkins, to exhibit against them for a fifteen-guinea cup. I have no objection to include Mr. Wills in the number, with Florence and Northern Star. But let Mr. Wills, Mr. Smith, and Mr. Perkins bear in mind their plants shall be judged in accordance with the rules annexed, and under no other arrangement will I attempt to exhibit; for let Messrs. Wills and Co. bear in mind we will have no repetition of the Kensington affair. I believe there are to be found eight men who are good judges, who will not be blinded by either prejudice or self-interest, or tarnish their honour for men or money. Let my plants be judged by the annexed rules, and if we should should be, as Mr. Wills asserts, bad cultivators, he will find the merits of my plants themselves will more than make up the deficiency, if he cultivates his to the best of his ability:—

1. Constitution sufficient for a bedding plant.
2. Distinct in character from those in cultivation.
3. Clean edges, the green not breaking through the zone.
4. Brilliance of colouring and novelty of character.
5. To be flat, or if slightly reflexed the better.
6. No plant to be considered *first-class* where the green breaks through the zone in quantity, this being a *fatal fault* in any Tricolor Pelargonium.
7. Each exhibitor shall have the liberty to object to any judges selected by either party.

JOHN WATSON.

St. Alban's, Oct. 2, 1867.

CENTAUREA RAGUSINA FROM SEED.—As I have been successful in the propagation of this useful and beautiful bedding plant, I am induced to offer a few remarks as to the way I proceed, if you think it would be at all useful to any of your readers, who perhaps, like myself, have found it difficult to strike from cuttings. I take up a dozen or so of this year's plants the first week in October, with all the root possible, and great care it requires too in doing so, for the roots are extremely brittle. I pot them in 32-size or five-inch pots, in some sweet loam, and put them in a close frame for a week, giving air gradually to get them hardened before winter, as if they are not well hardened they are very liable to damp off. I keep them in a cool airy place during winter, and water sparingly. They will produce seed in plenty the following summer, which I sow as soon as ripe, in boxes filled with equal parts of loam and leaf-soil with a little sand. As soon as they have made two rough leaves, I pot them up in small-sized pots, and treat them the same as old plants, giving them a shift into larger pots in March; they will then be in fine condition for turning out in May.

W. W.

September 30th, 1867.

Replies to Queries.

J. George.—Your seedling zonale, with large rosy-salmon flowers, in the way of Groom's Miss Martin, is one of the very best varieties ever raised. The flowers are of great size and beautiful in form, the petals freely overlapping, and the habit of the plant noble and striking. Of the trusses sent, No. 1 is a first-rate zonale, the colour intense red, with a slight tinge of violet. No. 2, a green-leaved variety, with large flowers of a deep rich scarlet, with white eye; very fine. No. 3, a good green-leaved nosegay, with large truss of orange-scarlet flowers. Nosesays can only be judged by plants, therefore we can only say of the truss that it is one of the very best. No. 4 is a zonale, with large flowers of a clear reddish-salmon hue. For so large a flower, the top petals are too narrow. You mark it as a nosegay, but it cannot be properly placed in that class.

T. S. Shorman.—Yours is a remarkably robust and handsome scarlet-flowering zonale. The flowers are second-rate in form, the top petals being narrow, but the colour is good, the trusses are immense, and the leaves almost gigantic.

L. Dean, Ealing.—Your selected African marigolds are a very fine strain, the flowers being globular, densely packed with florets, and the colours brilliant and pure.

H. Scott.—Two sorts of celery for exhibition: Northumberland Champion White, Manchester Giant Red. Twelve show dahlias: Baron Taunton, Midnight, Miss Henshaw, Miss Bush, Leah, Lord Palmerston, Hugh Miller, Lord Derby, Delicata, Bird of Passage, British Triumph, Dazzle. Twelve verbenas for pot culture: Alexandra, Lord Leigh, Marie Rendatler, Charles Turner, Duke of Cambridge, Imogene, La Grand Boule de Neige, Mauve Queen, Nemesis, Pallavicini di Brescia, Princess of Wales, Thormanby, Grand Duchess. Two cucumbers for exhibition: Champion of England, Mills's Jewess.

J. E. Dunstable.—You do not require inside borders for ground vinerias. The Black Hamburg will do you more service than the Sweetwater for the ground viney. We do not give the addresses of correspondents unless it is desired on both sides; it would be a breach of confidence.

Subscriber.—Your *Cordylina indivisa* must have good greenhouse treatment, and you must be patient. It will take many years to make a fine plant of it. In some cases plants and flowers are judged by the effect they produce as groups, and sometimes by their individual excellencies; it all depends upon the nature of the class and the terms of the schedule. In the case you put the judgment was wrong. Why should the committee be in any difficulty? If they see that there was a mistake, and the judges acknowledge it, and attribute it to the absence of the schedule when the judging took place, the only real difficulty the committee can have is to avoid repairing the error.

G. F.—For culture of *Alocasia* and *Caladium* see last year's volume, page 393 (September 1, 1866). Your plants must rest all the winter, during which time a temperature of 50°, or even 5° lower, is enough for them, if nearly dry.

Woodford.—You must use your own judgment. If your loam is good, you need not manure for fruit-trees; if it is poor, then manuring is advisable. In the case you refer to the loam was poor, thin, and overlying a bed of gravel, circumstances which rendered manuring particularly advisable.

Mushrooms in a Cellar.—Z.—You will see in this week's Calendar of Operations a note on mushroom cultivation. To grow them in cellars is an easy matter for a practised hand, but it is very seldom that persons unused to horticultural manipulations do any good in that way; and in any case it is questionable if the conveyance of a quantity of manure into the cellar of a dwelling-house should meet with encouragement from those who profess to guide the public in such matters. Our advice to a person living in a house in a West-End Square is, avoid the mess, the risk of health, and the dirt and trouble of growing mushrooms in the cellar. But if you will do it, procure at once about two cart-loads of rather dry short stable manure that has been turned two or three times, and make up a bed according to the directions given in the article in the Calendar.

The Gardener's Magazine.

SATURDAY, OCTOBER 19, 1867.

FREE STOCKS *versus* DWARFING STOCKS has become one of the questions of the day, in the discussion of the principles of fruit-tree cultivation. During the past few years, dwarfing stocks have been in great demand, and there are tens of thousands of trees on such stocks scattered about the country. Fruit-growers of the old school have never had faith in them, and fruit-growers of the new school begin to confess that they have been more or less disappointed. But the disappointment is not wholly the consequence of the adoption of dwarfing stocks. There has been too much said about the necessity of pinching trees on dwarfing stocks, and consequently many who have been led away by such teaching have pinched their trees and themselves too; for pinching carried on to a late period of the season results in the production of mere spray, and not of fruit-buds, as is the case when pinching is practised with skill and judgment. In cases where the possessor of a lot of fruit-bushes has become wearied of pinching, because of the miserable result, and has for a few years left his trees alone, they have made long rods; their vigour, formerly reduced, has been repaired, and they have actually become fruitful through neglect. Thus over-pinching, or summer pruning, has co-operated with the reduction of vigour consequent on the employment of dwarfing stocks to make the miniature fruit-garden more or less of a delusion. Yet there is a golden mean in this, as in other things. Dwarfing stocks have their uses. The quince will hasten the fruitfulness of certain kinds of pears, the paradise stock will do the same for some kinds of apples, and the mahaleb stock the same for cherries. The dwarf trees produced by grafting on these stocks are admirable for small gardens, particularly if summer pruning is discontinued in time for the wood of the season to ripen perfectly; not otherwise. When remarking lately on the uses of cordon training, we laid stress on the fact that this climate is not adapted for any system which promotes a late growth of the wood of fruit-trees; our autumns are usually damp, and sometimes cold. It is not wholly a question of temperature; it is a question also of relative humidity. In a moist atmosphere and a wet soil, trees still inclined to grow are quite disinclined to be fruitful the next season, and the prolongation of the system of summer pruning tends to keep the trees full of useless soft wood, that may be killed by frost, and if not killed is of little use the next season. Therefore, in any case, summer pruning should be brought to a stop by the beginning of July at latest. If any of our readers can tell us of trees that bear well in spite of pinching practised later, we shall be bound to give publicity to the particulars. We take the liberty to suspect that, upon the whole, the advocacy of frequent pinching has done more harm than good; but, in the practice of a thorough horticulturist, summer pruning is a most valuable means of increasing the total of bearing wood, and of aiding as an adjunct to dwarfing stocks in promoting early fruitfulness.

As to the stocks, it is quite certain that the quince, the paradise, and the mahaleb, do tend to render the pear, apple, and cherry trees grafted on them—if they live at all—precocious; and hence an amateur with a limited space for fruit-growing may have much variety in a small compass, and very good though limited supplies of fruit for his own enjoyment. But early fruitfulness is purchased at the expense of longevity. Trees on dwarfing stocks are of necessity short-lived; no one can point us to old, fruitful, healthy trees on such stocks, and as to large supplies, it is confessed they are incapable of affording them, for the trees never attain to sufficiently large dimensions to afford the necessary surface for large crops. Hence for gardens of any extent, for planters who wish for vigorous, fruitful, long-lived trees, Freestocks win the day, after all that has been said on both sides; and as to the matter of advocacy, the Dwarfing stocks have of late years had perhaps the best of it. We shall find in the best gardens of the country the free stocks in use and in favour. Men who have to supply quantities of superior fruits do not trouble themselves about quince, paradise, and mahaleb stocks; they go in the old track, though with no prejudice against improvement. What they want to know first is, if an alleged improvement is

an improvement, and the general verdict amongst the best fruit-growers in the country is, that dwarfing stocks are not upon the whole any improvement, especially when to other objections that may be urged against them, it is added, that some of the best varieties of pears, apples, and cherries stubbornly refuse to live upon them, or if they live, it is only like patients in hospitals, unfit for work, and with more or less of a prospect of death before them. We find at some of the greatest nurseries—as, for example, Messrs. Lane and Sons, Berkhamstead, Messrs. Lucombe, Pince, and Co., Exeter, and Messrs. Paul and Sons, of Cheshunt—the free stocks still in favour as productive of trees that live long, that are commonly healthy and vigorous, and that produce large crops of the highest quality possible for the several varieties, and the climate and soil in which they are grown. The dwarfing stocks beat them in point of time, that must be admitted; that perhaps is the only solid advantage to be derived from their employment. Such we believe to be the true state of the case, and we leave our readers to make their purchases, and order their work in propagating according to their wants and wishes, with this summary of the main points on either side to assist them in their decisions.

SOUTHWARK NEW PARK.—The People's Park for Southwark, situate partly in the parish of Bermondsey and the remaining portion in that of Rotherhithe, is rapidly verging towards completion. The principal entrances are three in number, viz., one on the north side, one on the west side, and one on the south. There are also three minor entrances. The lodges at the principal entrances are designed in a tasteful and decorative style. The aspect of the park, although at present in an unfinished state, attracts a large number of visitors, who appear astonished at the rapid progress that has been made in its formation. A large number of gardeners and labourers are employed daily in laying out the flower-beds and walks, and in transplanting young trees and many varieties of evergreens and flowering shrubs, some of which are extremely valuable and of foreign growth. Three drinking fountains are to be erected within the enclosure, and an ornamental fountain in the centre of a grass-plot, and which will be placed amidst a grove of trees and shrubs. The walks are gravelled and completed, and it is expected that the park will be opened to the public on or about Christmas.

CARNATIONS AND PINKS FOR WINTER FLOWERS.

The Editor has placed in my hand a letter from a correspondent who signs "Flora," in which a request is made for some particulars of the cultivation of carnations and pinks for supplying winter flowers. I very cheerfully render such aid as I can, though, as a grower of flowers for Covent Garden Market, I may not treat the subject in exactly such a way as would best suit the means of a private establishment. However, I dare say any gardener capable of growing a pink or carnation in a pot will be able to adapt my routine to his own range of practice, and I shall be content to describe how I should go to work to produce these flowers for market, where, I need not add, they realize remunerative prices.

The TREE CARNATIONS are those we must look to for winter flowers, and there is but one way of treating them on which we may rely for success, and that is to raise a fresh lot of plants every year, and to destroy the old ones as soon as they have furnished a sufficient number of cuttings.

The plants intended for flowering in winter and early spring should be struck in February, March, and April. There is no mystery at all about the propagating. Take cuttings of two or three joints in length, remove the lowest leaves only, put them into pans or boxes (boxes are *always* best), in sandy peat or sand alone, and shut them up close in a mild moist heat. Nothing like dung-heat for such things; but we strike a good many in the propagating house, over a tank. The first lot may be hastened and made better plants of by putting the cuttings singly into thumb-pots, from which they can be shifted on, and if the cultivator loses the early part of the season, and wants to make up for lost time, he must do them singly in pots, as by this method they have no check. When well furnished with roots, put those from boxes into thumb-pots, and those from thumb-pots into 60-size, and so on, always observing that they should not be shifted till they really need it, nor be allowed to get pot-bound and starving for want of a shift. Soon after the first shift nip out the points, or, in other words, "stop" them. But after this they must not be stopped again; this is very important. The pots must be well drained, and the compost should be turfy loam, with about a third of its

bulk of old cow-manure, and a fair proportion of silver sand. Continue to shift as required till the middle of July, when they may be in pots of eight or ten inches in diameter.

From the time the cuttings are rooted, the cultivator must use his own judgment as to the amount of heat they should be subjected to, the golden rule being to give them as little as possible, and to get them into frames and pits as soon as ever it is safe to deny them the aid of artificial heat. If driven hard, and much roasted, they will be covered with vermin, and more or less spoiled. From the time they have had their last shift, they should be put out of doors in an open situation, to make a stout growth and form their flower-buds. When their pots are full of roots, water them constantly with very weak manure water. It should never be strong, or it will poison them; it matters not what sort of manure is used, whether guano or the drainings of the dung-heap, or sheeps' droppings steeped in water, so long as it is such as you know to be suitable for plants, and so far diluted that it is decidedly weak. By this treatment, and the aid of a little occasional tying and training, you will have fine plants for winter flowers.

About the first of October is early enough to house them, as a rule, but if flowers are wanted extra early, they should be housed about the 20th of September. Keep them near the glass in a cool airy house for a fortnight; then transfer them to a warm greenhouse, and they will begin to bloom in November, and, by judicious management of the succession plants, flowers may be had until the end of March, or even later; indeed, any one desirous of having the flowers all the year round could do so, for a *second stopping*, and a shift in August of those struck in April would ensure blooms in March and April following, and perhaps even to May; but I cannot speak positively on this point, for I should not give them house-room after March, as there are so many other things then that would pay me better.

If the private cultivator has not the courage to throw away the old plants, he may let them remain in their pots without pruning, and with regular supplies of water till June, and then plant them out against a wall, and they will flower in September or October. Even then they need not be destroyed; they may be assisted through the winter with the help of mats, and thus may be kept many years. But if fine winter flowers are required, a fresh batch of plants must be raised every year.

The following varieties are good, and I might venture to say that all the varieties are good; however, these I select as most desirable. The best six are marked thus * :—

- Archimède*, yellow fringed, tipped red.
- Ariadne*, orange-yellow ground, crimson flake, fine form.
- Beauty*, pure white, pink stripe.
- Charles Baltet*, red, striped crimson.
- Delicata*, pure white, margined pink.
- Evening Star*, scarlet, and crimson flake.
- Garibaldi*,* purple, very sweet.
- Gloire de Permillieux*,* scarlet, dwarf.
- Hope*, scarlet, and crimson flake.
- Jupiter*, scarlet.
- La Géante*, blood-red.
- Magna coccinea*,* crimson clove.
- Osear*, canary-yellow, striped rose.
- Perfection*,* white, with bizarre flakes of purple and crimson, equal to a show Carnation.
- Queen of Whites*,* the best white, and a true clove.
- Souvenir de la Malmaison*,* rosy flesh, very fragrant.
- Vandael*, yellow self.
- Victor Emmanuel*, pure yellow, rosy-crimson flakes.

PINKS are easier to do, and we can employ them to fill up the blanks in the seasons when carnations are not to be had. We must include for our purpose the new hybrid or mule pinks, for they are most accommodating; as, for example, I have some splendid flowers now on a hybrid called *Napoleon III.*, which was sent out by Messrs. E. G. Henderson not long since, a rich crimson flower. The plants were struck in May last, and have been in bloom in pots out of doors since the 1st of October, and if taken in before frost occurs continue to flower until December. The way to manage pinks for winter flowers is, first of all, to strike pipings *as soon as you can get them*, and plant them out in well-manured ground as soon as rooted. At the beginning of October lift them carefully, and pot them in 32-size pots, put them in a cold frame until December, then carry them to the forcing house. Some of the hybrid or mule varieties may be struck in May, June, and July, and will afford flowers in winter and spring.

The following are the best varieties for this system of cultivation :—

- Anna Boleyn*,* rich crimson; this and the varieties that have been bred from it are invaluable for forcing.
- Garibaldi*,* crimson, with violet centro; fine.

Most Welcome, pure white, with crimson margin; a capital variety for late autumn bloom, to come in before the tree carnations are ready.

Tennison Pink.—This will be a good companion to the foregoing; the colour is pale rosy-pink.

Plato, light violet-rose, highly fragrant; comes in fine for early spring, and one or two blooms are enough to scent a large conservatory. All the foregoing are of the Anna Boleyn race.

*Napoleon III.**—This is a rich crimson, free flowering; by judicious management may be had in bloom any day in the whole year.

Marie Paré,* pure white; first-rate.

Dianthus hybridus multiflorus, bright carmine.

Prinee Imperial, crimson and white flake.

Rosette, rosy-pink, pure and bright.

Striatiflorus, carmine and pink.

ROBERT OUBRIDGE

Chureh Road Nursery, Stoke Newington.

STORING THE ROOT CROPS OF THE KITCHEN GARDEN.

I have already stated that those who are interested in this subject, should endeavour to understand the conditions it is necessary to secure to maintain the safe keeping of roots in such a state as will render them in a condition fit for table the whole time their season of use can reasonably last. Without some knowledge of this, and at the same time a desire to see it practically carried out, no good result can attend even the best constructed storeroom. It will therefore be necessary for me to endeavour to impress upon the reader's mind some of the conditions essential to the proper keeping of these subjects.

I have previously advised that a small current of air should be kept up in the structures in which they are stored during mild open weather; this is strictly necessary to carry off the obnoxious air which is sure to generate where such subjects are placed, and more especially so when a portion of the building is surrounded with earth. But as all may not understand the necessity of having these structures below the level, I may state for their information, that unless they are so placed they are not always proof against a severe frost; and that it is desirable so to construct them, that the internal atmosphere may not be influenced by the outward elements, and that one of the chief secrets of success is to maintain as near as possible an equable temperature inside the building. As this cannot be done when the building is wholly above ground, unless in very sheltered positions, the necessity for placing it partially under ground must be apparent.

It may be well at this point to direct attention to the condition of the roots of different vegetables when they are stowed away. In the first place, then, we can all understand that when such subjects as carrots, beet-roots, and potatoes, &c., are placed in their winter quarters they are in a state of dormancy. This being the case, we ought as readily to comprehend that it is important that no unfavourable influences should in any way act upon them; or, in other words, they should be safely guarded against any excess of cold, or it may speedily cause them to be unfit for use, and in the end to prematurely decay, while, on the other hand, if they are the least excited by warmth they will commence to grow, and soon become unfit for the table. But cold is not so injurious as heat (although none of them at any time ought to get frozen), but the least excitement brought about by a warm stagnant atmosphere is injurious to a high degree, as an unnatural growth is created, which can only be supported by exhaustion of the store of nutriment laid up in the root, which if allowed to continue any time seriously deteriorates the quality of the roots when sent to table. Hence the importance of admitting a current of fresh air into the structure during favourable weather, which not only keeps it pure, but of a more uniform temperature. I cannot imagine anything more disagreeable than having to enter a dark, dirty, and confined building, in which any quantity of vegetable roots are stowed away. Yet how often is this the case in places where we might reasonably expect better management; for all these kinds of roots give off more or less a certain amount of exhalations, which if confined to a limited space with no means of escape, soon pollutes the air of the room to a degree that no human being can bear with equanimity, until some portion of it has found an exit by the door which admitted him. We may rest assured when such a state of things exists (which it too often does) such a building is the most unsuitable for the purpose.

But while advocating the free use of a current of air through all structures in which these roots are placed, at all favourable opportunities, so that there may be a frequent change of the

internal atmosphere, I must not forget to warn the reader that its direct action upon such roots as potatoes would be an injury. A light covering of brakes or coarse hay should be placed over them, as an exposure to a current of fresh air would probably in time render them green, while the exhalation given off from the tubers would find its way up through any porous light covering. In storing potatoes great care should be taken that they are perfectly dry when brought into the store, as if damp, and they are laid thickly, a sort of fermentation takes place, to the injury of the tuber. This is especially the case when potatoes are taken up in dry warm weather, as then every tuber contains more heat gathered from the soil; and if housed in anything like a damp state fresh from the soil, a degree of warmth is generated when they are laid in large heaps that would surprise an inexperienced person. This fermentation not only acts upon the quality of the tuber, but it favours decay in those that are faulty or bruised.

It is also requisite that carrots be taken up when the weather is quite dry. These may be placed on one of the shelves as shown in the sections of storerooms given at pp. 439-440. They keep best when packed away in dry sand or coarse grit of any kind.

Beet-root requires the same care, but as this is subject to mildew it is best not covered; and the roots should be occasionally turned over, and any decaying ones removed. In fact, this remark applies to all roots when in the store, and a neglect to do so often leads to a greater loss in the bulk, to say nothing of the injurious effects of rotting roots being allowed to remain to create an obnoxious atmosphere in the room.

Scorzoneria and salsify should be taken up at the same time, and receive exactly the same treatment as the beet-root.

Parsnips being more hardy suffer nothing by being left in the ground until Christmas, or a few weeks after; but they will not endure any great amount of frost when taken out of the ground. In fact, they will keep in any place where they are not exposed to frost and the direct action of the atmosphere.

Perhaps the most difficult of all the root crops to keep is the onion; these will endure both light and air to a moderate degree. They should therefore be placed upon the uppermost shelves of the room, and be frequently examined to remove decaying roots.

As a concluding paragraph, I must have just a few remarks more upon the importance of thoroughly cleansing all roots before they are brought into their winter quarters. I do not mean that they should be washed, but such crops as beet-roots, carrots, and parsnips, should be well rubbed with the hands to remove all dirt; for when any quantity of dirt is brought with them into the store, it creates a certain amount of damp, which must at all times be avoided. I will now close by saying, that all the crops above noticed (except parsnips) should be housed by the middle of this month (October), and if possible during dry weather.

J. C. CLARKE.

MY ORCHID HOUSE.—No. XIV.

THE EPIDENDRUM.

This very beautiful and somewhat extensive genus is particularly well adapted for growing in a moderately cool house, for the species and varieties comprising it are happily endowed with a constitution by no means delicate. Amongst the species at present in cultivation are plants unmatched in the orchid house, some for the richness of their fragrance, and some for the beauty of their flowers; whilst *E. vitellinum* and *E. vitellinum majus* are very valuable for blooming at a time when the principal portion of orchidaceous plants are either at rest or their season of flowering is past. A difference of opinion exists amongst cultivators respecting the temperature for growing the Epidendrum species in. Some go so far as to assert that they can be grown with little or no fire-heat, while others are equally as strong in their belief that they do best in a high temperature, such as 65° or 70° through the winter, with a proportionate amount of heat through the summer. My idea of the most suitable house for growing Epidendrums is certainly not one without fire-heat, for I am quite certain, both from observation and practical experience in its culture, that the Epidendrum cannot be grown successfully unless it has the advantages of a house kept to a moderate degree of warmth. Some people, directly they see that such and such an orchid is recommended for growing without fire-heat, run away with the idea at once that it can be grown in an ordinary greenhouse, where the fire is only started on frosty nights; but certainly it is a vain delusion, for it very often happens that after all a temperature ranging from 55° to 65° is recommended for the winter, although the plant is said to do with very little

fire-heat indeed, or perhaps none. I fancy that it is anything but doing away with the necessity of employing fire-heat in their culture, for it requires a stronger fire than inexperienced persons imagine to keep up so high a temperature as 55° to 65° through the winter. Of course, in the summer, when the sun is powerful, fire can be dispensed with, and then people jump at the conclusion that it can be dispensed with altogether. My favourite temperature for the winter is 50°, which I consider is a very suitable one, neither too hot nor too cold. If it is allowed to exceed that (unless in bright sunny weather, when the glass can go up another ten degrees without injury), it is so much fuel wasted; while, on the other hand, if it drops below that, the heat will not be sufficient to dry up the dampness which will exist at that season in the atmosphere, and keep it healthy. Unless the atmosphere of the house in which the plants are growing is sufficiently brisk and elastic (if I may use the expression) to dispel damp, and that musty coldness which characterizes all plant-houses that are kept shut up without fire, it will be a matter of the greatest difficulty to keep the plants healthy and free from "spot;" and this disease is by no means a welcome visitor anywhere, for the leaves once spotted never recover themselves, even if they remain on the plants for years afterwards. A very essential point to be observed in the culture of slow-growing orchids like the Epidendrum, is to keep the atmosphere of the house in which the plants are placed dry during the winter. Another consideration equally important is to prevent the drip from the roof falling upon them, both summer and winter; in fact, if this is not guarded against, it is impossible to keep the plants in robust health. When the plants are in full growth they enjoy a moist atmosphere, but at the same time they are best without being syringed overhead, unless once now and then upon exceptional occasions, and by no means must the plants be syringed regularly, like the dendrobies and plants of that class. It is not of much consequence, certainly, if the foliage does get splashed in the watering during the summer, although it is a bad plan; but care must be exercised to prevent it happening through the winter, particularly if the plants are subjected to a very low temperature. In fact, during the winter, which may for our purpose commence now and terminate at the beginning of March, very little water will be required. About the middle of March the plants will begin to push, and as the growth increases so must the supply of water, and when the growth for the season is finished water must be as gradually withheld. If the plants have a glut of water in the spring, before they are able to absorb it, the roots will be sure to go, and when they are gone a whole host of evils will surely follow; while, on the other hand, if the water in the autumn is too suddenly withheld, and before the young bulbs have attained their proper size and maturity, they will shrivel to a certain extent, and it is useless to expect a strong spike of finely-shaped blooms from a dried-up bulb. Whilst on the subject of watering, it may be as well to observe that the plant in question will not stand being overwatered at any time of the year with impunity.

The Epidendrum can be grown in either pots or baskets, as the cultivator's taste may dictate. In either case, rough fibry peat suits it best. If all the fine stuff is shaken out of the peat it does not get sour so soon, and the roots run better. Of course the fine portion need not be wasted, as there are many uses to which it can be applied. The base of the bulbs must be kept well above the level of the pot or basket, and the soil packed well about the roots to keep the plant firm. If pots are used, the drainage must be first-rate to ensure a free healthy action of the roots; at least two-thirds of the pot should be filled with large pieces of crocks. A good time for propagating this plant is just as the young buds begin to push. The process is effected by division. I prefer that time also for repotting. The following species are first-class: *E. aromaticum*, *atropurpureum roseum*, *bicornutum*, *macrochilum roseum*, *verrucosum*, *vitellinum*, and *vitellinum majus*.

GEORGE GORDON.

A DESPERATE KILL.—Murdoch M'Aulay was once stalking with a gentleman, whose name shall be nameless, and who wounded a royal apparently to death; it was by a broadside. M'Aulay went on to bleed the stag, and had taken him by the antler, when he struggled up, and, making a rush, pinned him against the bank of the burn, leaving him only time to secure the other antler. Thus, with his back to the bank, and holding on by main strength and with great determination, he kept the beast from goring him. In vain did M'Aulay call to the gentleman to take his knife and kill the deer. My gentleman gave him words of encouragement, but little else, and at last ventured near enough to give the stag a little prod, which made him only more savage. "I shall be killed," said M'Aulay, "if you go on this way, for I have not strength to hold on much longer. Leave the stag alone, and just put my knife on the bank close by me, with the point towards the deer." It was with difficulty the cur—for he could not have been a gentleman—was persuaded to do even this. At last he did, when the gallant fellow, watching his opportunity, dropped his right hand, seized his knife, and buried it in the stag's heart.

FLOWERS AT PARIS.

BY ALPHONSE KARR.

Louis XIV. liked flowers with a strong perfume; he wanted an orange-tree in each chamber of his palace. Madame de Sevigny speaks of a *fête* given in honour of the "Grand Roi" where there were a thousand crowns' worth of jonquils.

A smell which did not please the king, but which made its way none the less, was the smell of tobacco, which Jean Nicot, ambassador of France in Portugal in 1560, sent to the Queen Catharine de Medicis. The names "Queen's herb" and "Medicean herb," under which it was at first known, recall that origin. At first we were content to smoke it, after the example of the savages, but ended by stuffing it up our noses. Boileau speaks of "tobacco kisses" (*baisers au tabac*).

It is strange to compare the lot of two sisters of the vegetable kingdom, the tobacco and the potato, both of the same family, and of the genus *Solanum*. The one, a violent poison, has spread itself over the whole world in spite of kings and the severest ordinances. In England they confiscated snuff-boxes, and King James I. made a poem against tobacco; Urban VIII. excommunicated snuffers, and I know not what Emperor of Russia cut off their noses. But the French Government having taken it into its head, first to put a tax upon tobacco, and then to take the monopoly of it and draw from it a large revenue, the other states were mollified, became tolerant, and protected this poison.

The potato, on the contrary, one of the highest gifts of Providence, since it produces "rolls" of bread ready made, met for a long time with insurmountable obstacles to its acceptance. In vain Louis XVI. caused them to be served at his own table, and carried a bouquet of its violet flowers in public. Parmentier only succeeded in enrolling it among our ordinary aliments through two circumstances.

He sowed it and gave it away; they would not have it. He caused a field of it to be protected, and published numerous prohibitions against pulling it: that was the first step; they stole it, and began to eat it.

But the famines, partly real, partly fictitious, which desolated France a little after, necessitated a recourse to potatoes for food.

So long as the potato was suspected they called it *Parmentiere*, but when it was accepted they did as was done with Christopher Columbus's discovery which was called America, and that of Niepce which was called daguerrotype.

One word more on tobacco. So long as it was only taken as snuff it was only a half-evil, for, after all, one is not obliged to embrace; above all, if, as Boileau says, one has a weak stomach. But tobacco smoked spreads itself all around, and poisons the promenades, public places, and carriages.

Individual liberty has a limit: it is the liberty of others. Could not those who love the odour of tobacco enclose this perfume in scent bottles with emery stoppers, which it might be lawful for them to smell at without imposing it on others.

The Queen Marie Antoinette was very fond of flowers; it was to flowers that she probably owed the last agreeable sensation of her life.

Shut up in a damp and infected chamber at the Conciergerie, she had no dress but an old black gown, and stockings, which she took off to repair with her own hand, meanwhile remaining with bare feet. I do not know if I should have loved Marie Antoniette, but who can help adoring such profound wretchedness?

A brave woman, Madame Richard, the portress of the prison, found means of giving a happiness and a luxury to her whom it was not permitted to call otherwise than the Widow Capet. She brought her every day, and not without some danger, a bouquet of the flowers which she loved—pinks, tuberoses, and, above all, rocket, her favourite flower. Madame Richard was denounced, and put in prison.

We see in a letter of Marie Antoinette's, recently recovered, that one of the circumstances which offended her the most cruelly in that unhappy affair of the "Diamond Necklace" was the audacity of the Cardinal de Rohan in saying or believing that he had "offered a rose" to the Queen, and that she had accepted it. "What! a man who had supposed that he had a rendezvous from the Queen of France! from the wife of his King! that the Queen had received a rose from him! I little merited that outrage." (Letters from Marie Antoinette to the Archduchess Marie Christine).

Later, another woman, who had been upon the throne too, Josephine, in her retirement at Malmaison, sought consolation from flowers. With the help of an intelligent gardener named Dupont, she brought together all the species and varieties of roses which France, England, Belgium, and Holland possessed.

Dupont several times raised roses from seed, and augmented the catalogue of rose-trees. We owe a portion of the roses which we now possess to the Empress Josephine. It is a crown which I prefer to the crown of laurels of her husband.

I was well acquainted with a pupil of Dupont, Hardy, who, at the Luxembourg, had created a *rosarium*, celebrated throughout Europe. Hardy was my master, and it was he who received me while still a very young bachelor of roses.

I saw long afterwards his vexation, at a period when the trees and the flowers encumbered the garden, and when it became necessary to replace them by stone balustrades.

He received the order to cut down the white and rose-flowering hawthorns, the laurinum trees with their golden clusters, and the service trees with their coral fruit, all at least one hundred years old, which were planted in great numbers on the terraces.

It is another of the souvenirs of my infancy destroyed; it is another of my first steps effaced in this Paris so embellished, I am told, but where, if I were to return, I should find myself as much lost as Tom Thumb in the forest, when the birds had eaten up the crumbs of bread which he had scattered on the way—

Dans les fleurs des lilas et des ébeniers jaunes
De mes doux souvenirs cachés comme de faucons
La troupe jeune et rit.

Hardy refused to give orders for the massacre of his trees, and absented himself for some days to avoid assisting at it.

The hawthorn, that pure and sweet attire of the hedges, is a flower which again plays a part in the history of Paris.

"On the 24th of August, 1572, King Charles IX. permitted that the Huguenots who were in Paris should be slain by the Parisians, and the other towns which copied the example of Paris put to death those of that religion who were among them. That blood-letting, although apparently somewhat cruel, prevented a great flux of blood." It is thus that St.

Bartholomew is spoken of in a book printed at Paris in the year 1640, with the privilege of the king, Louis XIV., then eight years old, and already in the book of which I speak represented with a crown of laurels, because the Duc d'Enghien had taken Thionville, because the Maréchal de Gassion had taken Gravelines, which was called the triumph of the arms of the king.

In a sadly different sense, I remember that one night, on leaving the house of I do not know what Parisienne, I reconducted home a very charming woman to the door of her own house: it was the first time that I found myself alone with her. Arrived before her house, we stopped before ringing; she had commenced some remark which of course had to be finished, then I commenced another so quick. It was such a beautiful moonlight, that we set to walking backwards and forwards for a space of some twenty paces before that door, she from time to time saying to me, "Good night, I must go in," and I, "a moment longer, it is not late."

It was very late, and we both knew it—so late that at this moment the infected odours produced by certain nocturnal works began to exhale.

This was so odious that she said to me, "Come, I must go in," and I no longer made any objection.

Only I can never separate that charming woman from that horrible odour, and I cannot think of her without fancying that I smell it yet, so that a journey having caused me some time after to quit Paris for a month I have never seen it again.

While, on the other hand, there are some of my souvenirs which, when I evoke them, exhale, the one a perfume of hawthorn, another of lilac, another of violets, lily of the valley, or honeysuckle.

I had often thought of the destiny of those poor daughters of the people who pass their whole life in the centre of the town in its infected and obscure quarters, and never hear the first words of love in their ears, and in their hearts, except in staircases smelling of rotten oahages, or under carriage-ways exhaling a mixed smell of mud and adulterated wine.

Thanks to these places planted with trees, to these public gardens established in each quarter, it is no longer so.

These squares, since the name is adopted, have other advantages. The games of workmen's children will no longer have the gutter exclusively for their arena, and, what is of still more importance, the square may re-establish "the quarter," which the omnibuses and the always increasing extent of the town have suppressed.

Now, here is the importance which I attach to the quarter.

Here, in the first place, is the way in which the squares may reconstitute it. In place of going to take the air by walking to a distance from their domicile, every one will take his walk and will come to take his seat in the summer evenings in the garden of his quarter. They will make acquaintance there, and, what is more, they will know one another; they will presently know that that pretty blonde is the daughter of a clerk in the administration, that that brunette is the daughter of a shopkeeper in the neighbourhood, that her companion is a dressmaker or laundress, that that woman that comes with a child is the wife of a professor in the Lycée, &c., &c.

Knowing themselves to be known, the women would have no longer any reason to adopt, to the great ruin of their family and household, these disguises, which no longer would deceive any one but themselves. They will dress in conformity with their station, their income, and their occupations.

At the same time that a pretty girl is met with it can be known whether she is honest and laborious. Marriages will no longer be made on the hazard of a chance meeting, or after a mutual falsehood, for one of the inconveniences of large towns is, that in changing his quarter one may also change his personality.

In two hours one may get rid of a bad reputation by merely quitting his street. A lazy drunken blackguard may go into another street to establish himself anew for some time as an honest and respectable man. It is something also to think that we may now see a fine young girl look at and admire flowers, instead of stopping before the stand and the shop windows of jewellers and mercers, these true looking-glasses for larks, where they are taken almost ready roasted by the fire of envy and ambitious desires.

It is singular that Paris does not possess a suitable flower market, or one simply covered-in like the other market places. Why is there not a well-stalled market for flowers, like the vegetable market or fish market?

There is another idea which I submit to the Parisian edility; then I shall stop—

The different royal and imperial chateaux, &c., possess a large number of orange-trees growing in boxes.

A round on a square! that might appear fine when the Parisians had never seen living orange-trees; but nowadays, when, thanks to the railroads, Nice is so near them, and when they all come to it, I declare that they will return to Paris very much disgusted with such an ugly magnificence. Every year these orange-trees are brought to the Tuileries and to the Luxembourg in their green boxes (what another horrible thing to paint in green the boxes, the benches, and all the furniture of the garden, this mineral green coarsely disagreeing with the vegetable tints!), then they are carried back into the glass-houses.

What should hinder that operation to be reversed?—for example, to plant the orange trees in the open ground in each of these gardens, to make of them a little wood or shrubbery, and in the month of October to enclose and cover them with a movable glass-house, which would be removed in the month of May?

Well, then, on the day of St. Bartholomew, the report was spread that a hawthorn tree that had been supposed dead was suddenly covered with leaves and flowers.

It was a text for the preachers of the time to say very fine things, and to prove how agreeable this massacre, this hecatomb of men, had been to God.

The fact is reported by De Thou, who laughs at the preachers.

A Parisian fashion for some time has been to wear a red pink in the button-hole of the coat. At ten paces off this made us fancy that the wearer was decorated with the legion of honour; at three paces it made us see that he was an ass.

In the successive embellishments of Paris, gardens at the windows have come to be definitely prohibited. These gardens were the subject of a struggle which dated from far back between the citizens and the police. There exists on this subject decrees against these poor gardens dated from the reign of Louis XIII. Some exist even of the Roman magistrates.

Martial speaks of a garden even more than that, even of a country, of an estate which he had himself in his window—

Rus est mihi in fenestra.

In return for the abstraction of this pleasure from the Parisians, and for having enlarged the town so much that all the neighbouring country has been engulfed and suppressed, the squares were due to them, only they need not have given it an English name. It is almost the only objection which I have to make to that idea, which is excellent.

The Egyptians singularly held to the air which was breathed in towns being corrected by perfumes, and caused them to be burned on the public places; there were day perfumes and night perfumes.

Aristotle says that the agreeable odour which is exhaled in the perfumes of flowers and prairies does not contribute less to health than to pleasure.

That has been for me individually one of the causes of my removal to a distance from great towns; and I have this happiness, that many of my happy recollections are impregnated with the sweet odours of the country and gardens—so much so, that the perfume of certain flowers tells them over again to me to this day. The smell of the furze in flower on the steep coasts of Normandy, the smell of cut hay beginning to dry, the smell of the rain of the thunder-storm, have all long stories to tell me.

REPORT ON TRIAL CULTURE OF LETTUCES AT STOKE NEWINGTON, 1867.

(Concluded from page 432.)

The only classification of lettuces attempted hitherto has recognized two classes, namely—

1. CABBAGE LETTUCES.
 2. COS LETTUCES.
- Each of these may again be divided into—
- A. Green-leaved.
 - B. Red-leaved.
 - C. Brown-leaved.
 - D. Spotted.

Synopsis of Lettuces grown in this Trial.

CABBAGE LETTUCES.

Green-leaved (A).—Berlin White, Batavian White, Berlin King's Head Brunzul, Coquille, Crisp Small Early, Crisp German, Drumhead, Early White Spring, Early Simpson, Emperor's Head, Early Silesian, Large Green, Versailles, Mogul, Neapolitan, Normandy, Imperial, Royal White Summer, Small Cutting, Stonehead Frame, Pas de Calais, Perpignon, Prince's Head, Turkish Butter, Triator, Stone Tennis Ball, White Tennis Ball, Tom Thumb, Switzerland, White Stone.

Red-leaved (B).—Bigotte, Blood Red, Blood-red Dark, Large Red, Mousseronne, Spotted Red, Red-eyed.

Brown-leaved (C).—Batavian Brown, Geneva Brown, Large Brown.

Spotted-leaved (D).—Snedeshead Early, Spotted Red Cabbage, Spotted White Cabbage, Spotted Large Cabbage.

COS LETTUCES.

Green-leaved (A).—Florence Cos, Giant Green Cos, Paris Cos, Giant White, Brunoy, Ivery's Nonsuch.

Red-leaved (B).—None.

Brown-leaved (C).—Brown Bath, Monstrous Brown Cos, Magdalen, Red Cos.

Spotted-leaved (D).—Spotted Cos, Improved Spotted Cos.

* * * The colour of the seeds affords no grounds for useful classification.

A Selection of the best Varieties,

Arranged in the order in which they became fit for use in this trial, the seed being sown on the 15th of April.

Cabbage Lettuces.—Early White Spring,* June 20; White Tennis Ball, June 20; Crisp Small Early, June 24; Stone Tennis,* June 25; Berlin White, June 27; Neapolitan,* June 27; Stonehead Frame,* June 27; Drumhead, July 1; Crisp German,* July 1.

Cos Lettuces.—Florence,* Paris,* Bath.

Varieties especially adapted for hot climates and dry soils.—Batavian Brown Cabbage,* Blood Red Cabbage,* Coquille,* Large Red Cabbage, Spotted Large Cabbage, Improved Spotted Cos, Red Cos.*

Varieties lasting longest after attaining perfection.—Berlin White,* Batavian Brown,* Brunzul,* Crisp German,* Drumhead,* Early White Spring,* Large Red Cabbage, Neapolitan,* Normandy, Royal White Summer,* Spotted Red Cabbage, Stonehead Frame,* Spotted White Cabbage, Florence Cos,* Red Cos.

NOTES ON SUCCESSIONAL SUPPLIES.

Some twenty or more of the varieties sent here by Messrs Barr and Sugden were set aside for trial in the open ground during winter, and were long since sown. It is not likely, however, that a trial of winter lettuces on our cold damp soil can be of any value, and therefore we shall, in all probability, refrain from reporting on the behaviour of those now on the trial piece. During the winter of 1865-66 we had fine breadths of the Hardy Hammersmith and Brown Dutch, but in the winter of 1866-67 even these hardy kinds were entirely destroyed. A dry sandy soil is best adapted for lettuces in open quarters to stand the winter, and shelter is of much less importance than dryness of the soil. But to keep up the supply of lettuces during winter and spring, frame-culture must be resorted to, and a considerable amount of skill and care must be exercised.

Lettuces for Winter and Spring.—There is a certain degree of risk attending the cultivation of lettuces in winter, no matter what is the nature of the soil or climate, or the varieties of lettuces employed; but the following routine will be found successful, as a rule, if followed with judgment and caution.

About the 20th to the 30th of August, the exact date to be determined by considerations of climate, soil, &c., sow two or three sorts of cabbage lettuce, such as *White Silesian, Tennis Ball,** and *Hammersmith.** As soon as large enough to handle, plant out the forwardest of the Silesian at nine inches apart each way, the others at six inches, but leaving in the bed all the smaller ones. Next prepare a sheltered border of light soil, raised above the level in a sheltered spot; fit it with frames and lights, and take the next forwardest plants, lifting them out carefully, and plant in the frames. The lights are not to be put on until frost or snow compel, and the winter treatment is to be such as to keep the plants as hardy as possible. There will still be some left in the seed-bed; thin them to about six inches apart, and leave them to

finish their growth where they are. By this method of procedure nice lettuces may be cut during the whole of December, January, February, and March.

Lettuces for April and May.—Some time between the 15th and 30th of October sow on raised beds in frames, put at a sharp angle, such sorts as *Wheeler's Tom Thumb Cabbage,* Early White Spring,* and *Stonehead Frame.* Also *Brown Bath Cos,** and *London Market Cos.* Keep the lights on till the seeds have started, and then give as much air as possible, taking off the lights on sunny mild days, and guarding chiefly against severe frost and damp. Should the plants get long-legged, or if they begin to damp off, sprinkle dry peat-dust, or dry silver sand (or both), amongst them. Keep thinning as fast as they crowd each other, never allowing their leaves to overlap. The thinnings may be planted out in other frames, if such conveniences are available, and from the time the plants have four or five leaves they will be fit for use for dressed salads, though of course too small to place on the table as lettuces. Begin to plant out from these frames in February, and continue planting throughout March, but leave a fair sprinkling of plants in the frames, if possible, to heart thro. Thus will be obtained capital supplies during March, April, May, and June, but the glut will come in during April and May.

Supposing some of these should fail, or the crop be insufficient, then sow in February and March a few pans of *Berlin White Cabbage, Early White Spring Cabbage,** and *Paris Cos.** Place the pans in a gentle heat; be very careful as to the amount of water given after the plants have got beyond the seed-leaf, or they will damp off. Keep them warm, and close to the glass. Prick out into pans or boxes as soon as they stand an inch high, or earlier than that if possible. Keep them growing freely, but do not push them so fast as that they will get drawn or sickly. Towards the middle of April give them more and more air, so as to be quite hardened for planting out, and thereafter during mild moist weather transfer them to rich sunny borders, and they will furnish fine lettuces from the middle of May till the end of June.

Lettuces for Summer use.—Sow in the open ground, from the 15th of March to the end of April, choosing a light friable soil for the purpose, such sorts as *Drumhead Cabbage, Tom Thumb,* Normandy Cabbage,* and *Florence Cos.** Plant out as soon as large enough to handle, on rich firm soil, selecting if possible for the later kinds, such as *Florence Cos,* a shady place, to prolong the season of supply. Any other of the many good varieties reported on may be treated in the same manner. There are two important points to be attended to, namely, to plant them out as early as possible, for if they stand too long in the seed-bed they will "bolt" as soon as the sun shines powerfully upon them. Another point is to give them room enough; the large-growing sorts, such as *Florence* or *Bath Cos,* will require to be eighteen inches apart, and the smaller kinds nine inches apart. They may be planted thicker, with a view to draw them before they have hearted, for lettuces are very well adapted for salads as soon as they have formed a little tuft of light green leaves three inches long.

Lettuces for Autumn.—Sow in the open ground where they are to remain, from the 15th of May to the 30th of July, such sorts as *Drumhead Cabbage,* Berlin White Cabbage, Florence Cos,* White Cos,* and *Brown Bath Cos.** Thin out and plant in odd places, but leave all the most thrifty plants to stand where sown. In damp cool seasons those planted out will make fine hearts, but if the autumn is dry and hot they will not be worth much. But those left to heart where sown will be first-rate, no matter what sort of weather they have, and some will be good for use even as late as Christmas.

To catch the market when Cos lettuces meet with a ready sale at good prices, sow in January the best Cos kinds, *Gray Paris* being perhaps the best, as it is the earliest to heart, and of first-rate quality. Put the boxes in a warm place to start the seed. Plant them out in beds, in pits, or frames, close to the glass, where they will have the benefit of the full sunshine. Thin them out in March and plant, but leave the beds well covered with plants to heart there; thus will be obtained very early supplies of spring-sown Cos lettuces with little expense or trouble. The nice point in the management is to secure quick growth without drawing them into a spindly character, in which case they never heart well.

In the foregoing particulars, wherever an asterisk occurs it is intended to mark the variety as one of the best of the series in which the name occurs. Endive-leaved and oak-leaved lettuces are not classed in this report, for they do not appear to be worth a place anywhere except in the *hortus curiosus,* or garden of curiosities, and there no doubt they would be valuable. S. H.

MR. H. CANNELL'S FUCHSIA NURSERY, WOOLWICH.

If we were to write a history of the origin, and to recite the progressive steps by which some of the founders of our most celebrated nurseries have ascended the ladder of fame, we fear that many of their present owners, in lineal descent, would become abashed at the recital of the difficulties which they had to contend with in their endeavours to develop their present resources. Perseverance and constant energy combined surmount many obstacles; therefore, however insignificant may appear the earlier stages of a work, yet if those qualities are inherited by the individual who has the conducting of it, we may have confidence as to the accomplishment of something more than ordinary results. We believe all this is inherent in Mr. H. Cannell, and we should surely have proof enough if it were only in connexion with the recent introduction to public notice by him of the benefits that accrue from adopting the extension system in the culture of the vine.

We did not anticipate, in our visit to the nursery, to find that it occupied a large area, abounding in all that is choice belonging to horticulture and floriculture. On that score the visitor will be disappointed, for at present the limits of this nursery are circumscribed within a very narrow compass. Though true to his motto, in respect to his advocacy of the culture of the vine, so is Mr. Cannell seeking to extend the sphere of his labours. Already he has obtained a plot of ground that covers a portion of the embankment in a line with the Woolwich Dockyard Railway Station, so that passengers by the North-Kent Line, at that spot, are afforded a beautiful floral treat, as the whole of the ground is covered with flower beds, forming at once a complete flower-garden, abounding, during the bedding season, with some of the rarest gems of floriculture. As one of his chief objects is here to test the qualities of the different kinds of plants that are supposed to be adapted for bedding, or rather for improving the effect of the flower garden, the beds for the most part were planted with the various dwarf tropeolums and verbenas, descriptions of which are to be found in his catalogue. Of the latter, we would say it is something more than a list; in fact, it is a treatise in brief on the growth of many interesting florists' flowers. For the cultivation of the fuchsia, there can be no safer guide, for

I know somewhat about his achievement in that respect, having at one period been a rival competitor with him at our leading metropolitan exhibitions.

Of his nursery stock there is nothing remarkable for size, as his present space will not admit of it; but it embraces every variety of both new and old fuchsias that are really worth growing. Verbenas, petunias, both double and single, mimuluses, heliotropes, lobelias, antirrhinums, and every thing else that is worthy of being cultivated among florists' flowers, may be found here in plenty. As he purchases the stock of many new and valuable flowering plants, of course through him they are issued to the public for the first time. He also obtains every novelty of note as soon as it is to be had in the market, from which large quantities of the said varieties are afterwards propagated for sale. But one very novel but useful feature in his dealings, is the sale of small seedlings of the various kinds of popular greenhouse florists' flowers that are generally treated as annuals, such as cinerarias, calceolarias, primulas, &c. This is a great boon to many who are disappointed in the rearing of their seedlings, or otherwise do not trouble themselves to sow the seeds. The same, in large numbers, can be forwarded through the post. In closing these few hasty notes, we have only to say, that should Mr. Cannell continue to be favoured with his health, we believe, under such circumstances as now influence its direction, that this nursery will attain a place in the foremost ranks. JOHN F. McELROY,

ROSES AND ROSES.—No. IX.

ROSES ON THEIR OWN ROOTS FROM AUTUMN CUTTINGS.

It is not generally known that the hardier kinds of roses may be raised in any quantity from cuttings taken now, and planted in the open ground or in frames. This mode of propagating is described at length in the "Rose Book;" but, as all our readers do not possess that, a few simple directions may be appropriate here, as this is the season for the operation. This mode of propagating has been pursued here during several years past, as a regular item in the autumn work, and several attempts have been made to collect from our own practice a few statistics which might prove useful to others. But the statistical part has been neglected, solely through want of time to reduce to form the particulars furnished me by the garden book. On several occasions the cuttings have been carefully labelled, and a fixed number—as, for example, say a hundred—of each variety have been inserted, and in the following summer a record has been taken of the number of plants resulting from the hundred cuttings in each case. These records are somewhere; but it is quite possible they may never be found. But it matters little, after all; for the varieties of roses in favour change so regularly and frequently, that by the time we have discovered that a particular sort is very shy of rooting from autumn cuttings, that particular variety will perhaps be superseded; and so, after all, the *general case* is that which really interests us. It is to the general case, then, that I shall now address myself.

To strike roses from autumn cuttings, one of the first essentials is that the cuttings should have plenty of green leaves on them. The next essential is that the shoots selected should be growths of the same year, quite hard and stout, and pretty well ripened. Old wood is no use, and quite green, sappy, soft wood is no use. To have ripe shoots that have done growing, and on which the leaves remain quite green, we must go about the business in the month of October; and this very day, the 19th of October, is the best date possible for nearly every district in Great Britain. Down south and far west they may go on taking cuttings till Christmas, perhaps; but even there it is not advisable to postpone the job, because spring will come, and start the sap into motion before the cuttings have had time to form a callus, which usually is all they do during winter. It is with the first movement of the sap in spring, when the leaves begin to push, that roots are formed; and hence it is desirable to allow the cuttings to remain a whole year in the spot where they are in the first instance planted.

Let us consider the simplest mode of all. Dig over a piece of ground favourably situated for the purpose—that is to say, that is not quite a marsh all winter, and that has a little shelter of some sort. When the ground is moderately dry, and may be trodden down without making a paste of it, put in the cuttings, and tread between them to make them quite firm, and then leave them for the winter. It may happen that the ground is too wet now for the business, and you may fear that the season will be lost, seeing that the 19th of October is pronounced the best date for the work. Now, there is no excuse for losing the season at all; for the cuttings may be taken, say, to-day, and be stuck into the ground or into a heap or bed of cocoa-nut fibre, and left there for a month or more, and may then be planted where they are to remain. The object of cutting them at once is to give them a chance of forming a callus while they still have green leaves upon them, which they are less likely to do when the leaves have fallen. I think I once proposed the 15th of October for taking the cuttings; the fact is, a few days either way is of little consequence; but if the cuttings are not made before October is out, you must not expect any of them to produce roots. It

has been our custom to put in a few thousand cuttings every year, and, as remarked above, they have been carefully tallied, in order that we might have exact particulars of the percentages of successes and failures with the several varieties. But the records have never been overhauled, and I can only speak generally, and say that, if properly done, and if robust-habited kinds are cut from, open ground plantations will yield about 30 per cent. of all the cuttings inserted in the shape of fine thrifty plants. Some kinds, such as *Madame Vidot*, will perhaps never make a single plant, even out of thousands of cuttings; other kinds, such as Jules Margottin and General Jacqueminot will give 90 per cent. The records that we have somewhere of experiments with some two hundred varieties, would be valuable to tell us how some favourite sorts behave, but it is quite possible we shall never find them.* Dr. Denny, and our frequent and much-valued contributor, W. D. Prior, Esq., have seen our plantations, and I think they will agree that when I sum up the total result at 30 per cent., I am fairly under the mark, and might have ventured so far as to fix the ratio at 50 per cent. But one in three is worth having, seeing that they may be planted four inches asunder in the rows, and the rows six inches apart, at which rate a rod of ground will hold 1633 of them.

To make the cuttings properly is half the battle. Look amongst your roses now, and you will observe, if they are at all like mine, two sorts of wood. One sort consists of long fat rods like willow wands. If they are soft and pithy, they won't do. Another sort consists of rather wiry shoots of moderate length; these are hard, not so green as the fat rods, and are woody, not pithy when cut through. It is from these the cuttings should be taken. Now observe, little bits such as would do in a gentle heat in summer are of no use at all for this work; they will simply die. Take a medium-sized firm shoot and cut it into lengths of six to nine inches; it matters not at all about cutting to a joint; the prevailing theory about cutting to a joint causes a great waste of wood in making cuttings. Do not remove any more leaves than will suffice to leave two clear joints to thrust into the soil; let all the other leaves remain, and the longer they remain the better. Whether the bed is or is not ready to receive them is of no consequence at all; the grand thing is to make the cuttings and properly prepare them at once, and stick them in a bed of cocoa-nut fibre in the open air, and there let them remain until they can be planted properly, which should be done some time in November.

So far in respect of the simplest method of procedure. Let us say that by this system we get 30 per cent., taking the sorts commonly in cultivation, and with none of that judicious selecting of varieties which might be practised had we but the statistics, so carefully made and so unfortunately lost, to guide us at this juncture. Alack! alas! &c., &c., &c., &c. Now for a safer way, and one that will pay for extra trouble, and that is to do the work in frames; and the way to go about it is as follows: Select a dry well-drained border, and if you have not such a border, make one. It must be, to use a country wife's expression, "as dry as a bone," and the way to make it so is to form a bottom of rubble, and on that to put eighteen inches depth or so of good sandy loam—if half sharp grit and half friable loam, perhaps better than anything else. Now let us consider why we use frames. The employment of glass preserves the leaves for a great length of time, consequently the callus is more quickly formed, and in spring growth begins early and roots are produced long ere those in the open quarters have made the slightest move. Therefore, every way the use of frames is desirable, and the result will be 60 per cent. if the varieties are taken indiscriminately from a good collection, and the management is good. As to the preparation of the cuttings too, there is an advantage in the employment of glass, that a rod capable of furnishing two cuttings for the open ground will furnish three for a frame, for they may be shorter; in fact, good cuttings containing two or three joints are quite long enough. The way to go about the business is to make the cuttings instanter, and if the bed is not ready, to put them in a bed or box in sand or cocoa-nut fibre *under glass*, where there is no artificial heat, until they can be put in the bed prepared for them. Supposing the bed and the frames to be ready, plant the cuttings as close together as possible, even if their leaves intermix considerably, and put the lights on and keep them on, giving no water at all. The lights will keep them green for six or eight weeks after the roses in the open ground have become leafless, and there will still be time for them to shake off their leaves and go to rest, preparatory to a good start in spring.

Now, I haven't done with this subject; there is a way yet to make sure of ninety per cent., and this with scarcely any

* If this should meet the eye of Abel Hoyle, who had the management of the rose cuttings two years in succession, he may be able to throw some light on the subject.

regard to the peculiarities of varieties. Make your cuttings at once; short wiry wood of this season is the best, fat pithy shoots won't do. Tie them in bundles of about half a dozen each, and heel them into boxes filled with cocoa-nut fibre, or failing that pure sand. Stick in the bunches aslant and press them firm, and then tilt the boxes so that the cuttings will be nearly horizontal. I wonder if I am understood? A cutting placed upright does not form a callus so soon as one placed horizontally; the law of the movement of the sap explains all this; but the fact must suffice for the present, as we are dealing with practical matters only. Now you can put them into a nearly horizontal position by sticking them in this way ; and pressing them as firm as possible, and then tilting up the boxes so as to bring them to a lower angle thus: . A cool light greenhouse is the proper place for them, and soon after the turn of the year, when their points begin to show a fresh green colour, indicative of growth, the boxes should be carefully tilted in an opposite direction, so as to bring them nearly upright. You will learn by practising this process how much position in reference to the centre of the earth, or in other words, how much the action of the law of gravitation has to do with the life of plants. When puthorizontal, growth of leaves is checked, and the formation of a callus promoted. When changed from this attitude to the perpendicular, the growth of leaves and roots is promoted: this is a bit of horticultural conjuring, as simple as all other conjuring, but it is not for every fool to understand it. And talking of fools fills me with a strong desire to extinguish for ever that race of would-be practicals who, because they cannot strike a dozen roses from autumn cuttings, have the impudence to pronounce the feat impossible. I thank God I have no power to annihilate anybody, else I am sure my temper would compel me to obliterate a gang of grumbling idiots who have tried my plans and failed. How coolly some of these have civilly told me that roses on their own roots are impossible! and with what wonderful stoical indifference and Brummellian politeness have I allowed them to have their say, even in my drawing-room, which is within two hundred yards of the spot where for ten years past we have raised thousands of roses on their own roots by the plan first described here, and have exchanged them with the trade for other things required for our own experiments! A great swell once got into our fruit garden, where this business is conducted, and offered me thirty pounds for five hundred of them, but I told him I would give him one as a sample, and as for the rest it was quite a mystery what

could supply roses of the same pattern cheaper than I could, for they do not pay at the rate of thirty to sixty pounds an acre for land, as I do. But I don't mind adding, for the encouragement of rosarians everywhere, that, at the enormous price of land in this rural suburb, I could make a good income by growing roses from autumn cuttings; let every reader interested in the matter deduce conclusions for himself therefrom.

The own-root system has been strangely damaged by the utterances of fools. Generally speaking, fools have small influence, as a man who has lost his gravity has but little weight in society. But some very respectable people have played the fool in this matter. They have made use of soft pithy rank wood, or of miserable mites of good ripe wood, and have planted these late, when the leaves were falling, and have taken care to plant them loosely in wet soil, and have lost all, and then raised a hue and cry about the absurdity, &c., &c.

Bah! yah! It was absurd for Columbus to sail westward; it was impossible (see Lardner somewhere) for a steamship to go to America, for the weight of fuel necessary would be more than a ship could carry,—and the impossibility of own-root roses belongs to the same category of fooleries. Let those who are too stupid to strike a rose on its own roots hold their tongues; all they say about the impossibility is simply a publication of an addition to the pedigree of asses. This remark does not of course apply to our friends who make no pretensions to skill in horticulture. Many people know, or believe, they cannot succeed in propagating, and they never try. I confess I cannot drive a nail straight, so I take care not to boast of my skill in carpentry. If I professed to be an amateur carpenter, and failed to drive a nail straight, I should deserve to be called an ass; and it is for the pretenders, the people who talk much and do little, that I wind up this seasonable paper, with the advice, that henceforth the less they say about roses on their own roots, the less is their risk of betraying themselves as proper candidates for the cap and bells. This was written for the especial service of O P Q, who wishes to be referred to as seldom as possible. He is getting on, and we shall see by and bye—if the Crystal Palace does not shut up, as it ought to, for the rose shows there have become mockeries and shams—that O P Q can do something in the way of growing and showing; and I should not wonder but some time in 1868, if we are both spared, he will present me with a well-bound copy of the 25th edition of the "Encyclopædia Britannica," in acknowledgment of the service rendered him in these papers. I wish he would, but I never put my trust in princes. S. H.

ROSE CUTTING PREPARED FOR PLANTING.
(To be planted as deep as the line A.)

would become of them; I should never sell them, and yet they would disappear without being destroyed. Messrs. Paul and Son, of Cheshunt, or Messrs. Lane and Son, of Berkhamstead,

WHAT is the difference between a honeycomb and a honeymoon?—A honeycomb consists of a number of small "cells," and a honeymoon [often consists of one great "sell."

Calendar.

WORK FOR WEEK COMMENCING OCTOBER 19.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—There is nothing to be done now but to keep the ground clean by the use of the hoe in dry weather, and to lay down broccolis as directed last week. Plant cabbage, collards, endive, potato onions, cauliflowers, under hand-glasses, Hammersmith and other hardy lettuces. Vacant plots to be trenched two spades deep, and laid up in rough ridges for the winter. Move all refuse to the rot-heap, to prevent litter and waste; whatever will rot into mould is of value as manure.

ASPARAGUS BEDS must now be dressed for the winter. Cut off all the tops, carefully weed the beds, slightly break the surface with a hoe, taking care not to injure the roots, and cover the bed with four inches depth of rotten dung. Do not disturb the alleys.

BROCCOLI.—Those heading now must be protected in case of frost. A very simple way of accomplishing this is to snap the midribs of a few of the outer leaves, so that they will fall over and cover the head without being quite separated. Plants that will have to stand the winter must be treated according to the climate of the district. In the southern and western counties broccolis stand ordinary winters without harm, but in many places they are so frequently killed that some assistance must be rendered them. A very simple and effectual method is to heel them over with their heads to the north: this checks growth, and enables them to resist severe frosts. But if the plants are forward and strong, it is advisable to lift them and replant them, and lay them in trenches with their heads to the north, and with earth covering their stems as high as the leaves. They help each other much when planted close, and that is why a few weeks back we advised planting them a foot to fifteen inches apart.

CABBAGE may be planted in vacant beds during fine weather. As for the sorts, it must depend on what the seed-beds offer. If plants have to be purchased, secure if possible plenty of *Rosette Colewort*, *Enfield Market*, and *Dwarf Early York*.

ENDIVE.—Plant the last lot on a warm dry border. Blanched endive will be in demand now that most other saladings are scarce, and a few plants should be covered every eight or ten days to keep up the supply.

SEAKALE for forcing may be taken up now and laid in under cover, but in a cool exposed place. This will give it a cheek, and cause the crowns to ripen preparatory to forcing.

BEEF must be taken up and stored.

CARROTS must be taken up and stored.

ARTICHOKES must be cleared of flower-stalks, and have a little protection at the roots; the amount of protection to be increased as the winter advances.

SCORZONERA AND SALSIFY.—Take up and store.

PARSNIPS.—Take up and store if the ground is wanted; if not, let them remain, and dig them out as required. They are much more buttery and sweet when cooked if but recently taken out of the ground.

Flower Garden.

AMERICAN PLANTS may be moved now better than at any other period of the year. *Rhododendrons*, *Kalmias*, and hardy *Azaleas* are in splendid condition at the nurseries this season, full of flower-buds and strong wood of the year, so that *malgré* accident of weather there will be a grand bloom next spring. Whoever plants these must be sure in the first instance that the soil is suitable. Many of the natural loams about London suit them admirably, and, on the other hand, there are many otherwise good loams in which they will not grow at all. It is only to be determined by experience on the spot, and where there is any doubt, the only safe course is to cart in peat from the nearest source of supply in the district. We use a mixture of yellow loam and peat from Wanstead, equal parts, and prefer it to all other soils for fine-rooted plants. *Pontic Rhododendrons* and their varieties are the least particular about soil of any of the race. Some of the best hybrids will grow in any leafy mixture with plenty of sand. Mr. Standish has one—and a beauty it is—named *The Gem*, which grows best in pure sand. Clay or chalk will never do for any of the race, but loamy turf and leaf-mould are of great service either to increase the bulk of peat where it is an expensive article, or to take its place entirely where it is difficult to obtain it. In any case American plants must have a soil in which their fine hair-like roots can run, and quite free from salts of lime, which poison them; good fibry peat is the only material in which any great variety can be grown, and that is abundant in almost every part of the country. As they never root deep, an excavation of two feet is plenty in the making of a bed.

CHRYSANTHEMUMS are opening well and early this season. All delicate flowers should be bloomed under some sort of cover, to protect them from heavy rains. While the various varieties are in bloom, make up the list of what you intend to grow next season; and for specimen culture begin to insert cuttings at once.

DECIDUOUS TREES may be planted now *ad lib.* No occasion to wait for the falling of the leaf; never mind if they are as green as in July; take them up, and dispose of them as required; the shift will do them more good than harm. Fruit trees, roses, forest trees, ornamental shrubs, and all such things may be ordered in from the nurseries, and planted at once; and from this date every day gained is a real gain for the future well-doing of the trees, which will begin to make roots directly, for the ground is *now warm*, but from this time will get cooler every day, and the longer planting is delayed the longer will the trees require to make more new roots, on which their vigour next season will depend. Never plant while the ground is in a sodden state; if it does not crumble freely, wait a bit; meanwhile lay the trees in by the heels, to prevent injury to their roots by sunshine and drying winds.

HARDY HERBACEOUS PLANTS.—This is the best time in the whole year to form and plant collections, and this is a fortunate circumstance, because in arranging them for effect various hardy bulbs may be planted at the same time. Such things as primulas, polyanthuses, daisies, &c., &c., may be parted and planted, and will be sure to make new roots immediately if the earth is pressed firmly to them.

RANUNCULUSES AND ANEMONES.—It is full time to prepare for planting these showy subjects. Autumn planting is certainly to be preferred except in special cases, such as a wet soil, a very bad climate, or a compulsory prostration through stress of weather, or some other circumstance. These bulbs require a well-drained, rich, mellow loam. It is a matter of fancy and convenience how and where the bed should be placed, except that an open sunny spot is imperatively necessary. When grown in collections, they are

planted in four-feet beds in rows five inches apart, and the tubers five inches apart. Some growers allow six to eight inches every way, in order to secure finer flowers. When effect is thought more of than exhibition qualities they may be four inches apart every way, and will do well. In preparing the bed, let it consist of two feet depth of mellow turfy loam, with a sixth of its bulk of quite rotten cow-dung added. Prepare the bed a few weeks before the time for planting, if possible, and in any case let it rest a few days to settle. The best way to plant is in drills. Some growers simply lay the tubers on the bed claws downward in lines, and then cover them with two inches depth of sand; others dibble them in as beans are sown by farmers. It matters not which way the planting is accomplished, so that the tubers are not more than two inches deep, and are arranged regularly. As to sorting them in colours, that is a matter for the cultivator alone to consider, but it may as well be remarked here that if planted without any consideration as to colours, the effect when they are in flower is likely to be as good as if the most elaborate pains had been taken. The ordinary bulb lists contain the names of the showy kinds, which are most useful in gardens, but persons forming collections would do well to consult the lists published by Mr. Carey Tyso, of Wallingford, Berks.

MYRTLES require protecting in almost all parts of Britain, though in the southern counties we find them hardy on south walls. There is no plan so good as to mat them, but a few branches of spruce or any other dense evergreen thrust in the ground in front of them will screen them very effectually from severe frosts. There will probably be no need for any protecting till after Christmas, but there will be no harm in thinking of the matter now that frosts are to be expected. Myrtles in pots can be kept anywhere out of the reach of frost; even a dark shed suffices, and for the window there is scarcely any plant more welcome.

Roses of all kinds may now be planted—provided, of course, they have already been growing out of doors. People who obtain recently-made roses on Manetti stocks full of luxuriant growth, through quick cultivation under glass, must not plant them out, for the first frost will kill many, perhaps all. Brier and bush roses from open plantations may, however, be lifted without any risk; the leaves will flag, of course, but that is no matter; they have done their work for the season. The work now to be done in the rose garden consists in pruning, renewing stakes, cutting out suckers, heading back rods that have been budded, and in deep digging and liberally manuring plots intended to be planted this season.

HARDY HERBACEOUS BEDDING AND BORDER FLOWERS.—Now that the beds are being cleared of their summer occupants, we may again say something of hardy flowers. To grow herbaceous plants in a satisfactory manner, a good deep sandy loam and an open sunny position are the first requisites. To be sure, many beautiful subjects will grow in the worst of soils and the worst of situations; as, for example, *Solomon's Seal*, one of the most elegant plants in English gardens, will thrive in the deepest shade and the most trashy soil. So of many other things. Nevertheless, for anything like a collection, the beds and borders require to be exposed to all the winds of heaven; they should not be overshadowed by trees; they should be well drained, yet naturally retaining a certain degree of moisture all the summer, and in the first preparation a liberal dressing of manure should be deeply dug in, and the soil left quite rough until the time of planting. The month of October is the best in the whole year to prepare the beds and borders, because bedding plants can then be taken up, and, if desirable (and it is *very* desirable), a variety of early-flowering bulbs may be planted with the herbaceous plants; and November is the best time to plant both classes of subjects. Just in time, therefore, for everything needful. If the work cannot be done now, the preparation of the ground may be attended to any time during winter, and the planting may be performed in February; but we say emphatically, now is the time to prepare for a display which shall begin with the dawn of spring, and change continuously all the summer long, and even show some gaiety in the gloomy months of late autumn and winter. There are two points of the utmost importance—first, as to the disposition of the ground; and, second, as to the order of the planting. The elaborate parterre is not adapted for such mixtures as we contemplate in our herbaceous garden, though many of our hardy herbaceous plants are invaluable in the parterre—as, for example, *Delphinium formosum*, *Alyssum saxatile*, *Aubrietia purpurea*, *Iberis saxatilis*, *Arabis albidia*, *Tritoma glaucescens*, and others, which may be used as true bedding plants with the most splendid effect. But the majority of garden lovers enjoy these things best when mixed without plan, when thrown together as Nature plants her wild flowers in the hedgerows, and with a background of shrubs to give relief to their colours, and with clumps of trees to separate the different borders and clumps from each other. By this method, there is always something to charm the eye, and every separate spike or umbel is seen to the best advantage. Long experience in the midst of every kind of floral display has made us rather indifferent to gorgeous effects of the true bedding school. They are too much like fireworks, and it would be better, perhaps, if they were as evanescent, for it is very wearisome to see for months together the same great patches and belts and mixtures of dazzling colours, composed of a few varieties of plants that have really no grace or interest at all to recommend them. For a good collection, then, I should prefer an irregular garden, with patches of green turf, clumps of trees and shrubs, broad and narrow borders, isolated patches, a few mounds rising to belts of shrubs, so as not to look like mere heaps of dirt, and one or two large beds, on which to make a special display of plants notable for beauty, yet so different to things commonly used for display as to be at once novel, peculiar, and interesting. As to the arrangement of the plants, that, like the disposition of the ground, must be matter of taste. There is, in fact, only one serious remark to be made upon this subject, and it is this, that at the time of planting the planter must know what height the several subjects will grow to, or some little things will be lost, and some large things will be made obtrusive and inelegant. When *Tritoma uvaria* is seen at some distance, and its fiery flowers glowing like a burning torch ("torch-lily" is a good name for it) against a background of shrubs, its appearance is stately and magnificent; but when leaning forward in the front of a narrow border, it is far less beautiful, and gives one an uncomfortable idea of the danger of being burnt in passing it. Not much can be done to contrast colours in these collections, because plants in the same row, of different colours, will for the most part bloom at different seasons. However, as a large proportion of these plants bloom in June and July, it is well to arrange them so that they contribute to each other's beauty. The scarlet *lychnis* show well beside a clump of *Lysimachia thyrsiflora*; blue and white *anemones* help each other; the gorgeous *prunias* show to great advantage in clumps unmix'd with other flowers, or in the fronts of borders which have backgrounds of shrubs or ivy. To regulate all these matters is impossible, and, fortunately, not desirable, as it is the employment of the mind in inventing and arranging that ladies and gentlemen desire, quite as much as the gratification of the eye by various displays of

colour. Next to the foregoing considerations, the most important is the protection of the plants from vermin. This subject may appear to belong to the after details of individual cultivation, but in reality it must be thought of *now*, and for this reason, that herbaceous plants may be planted in positions where it is impossible to protect them from the ravages of vermin, and in such a case the labour and money are lost, and a most interesting subject is brought into discredit. We will cite an example. An amateur holding a pretty garden, which was divided from another by an old privet hedge, determined to plant a collection of the best herbaceous subjects. He knew the hedge was inhabited by thousands of snails, and he thought that by vigilance he would gain the mastery over them, and save his plants. So perhaps he might have done, if the hedge had been all that he had to deal with. He forgot that the next garden received but little attention, was almost run wild, and was in fact a great nursery for snails, slugs, earwigs, woodlice, and every other plague that brings death to choice plants. He planted his collection on a border, to which the dividing hedge served as a background; the vermin found out his treasures, they poured in, and devoured nearly one-half of the collection, which comprised several hundred choice species and varieties. Such things as *Fraxinella*, *Saponaria*, *Delphinium*, *Antirrhinum*, *Lycnis*, *Pentstemon*, and *Phlox* are devoured at once and lost for the season, and when those are gone less palatable things suffer. In such a spot, however, many charming things can be grown. Snails and woodlice care very little about priuresses, so that a collection of the choicest double kinds may be planted in the midst of hungry vermin. Lily of the Valley, Solomon's Seal, *Anemone Japonica*, *Callirhoe digitata*, *Ranunculuses* of many kinds, and a hundred other good things, will not be harmed by snails, and are therefore useful in gardens unhappily circumstanced in respect of vermin. An open sunny spot, removed from the shade of trees, and exposed to all the winds of heaven, is that which will best suit the majority of the plants, and in such a spot there will be less vermin of all kinds than near walls, fences, rockeries, rooteries, and other such harbours for marauders. There are many hardy subjects adapted for bold clumps, and, if well managed, produce a splendid effect. A dry, sandy, sunny bank covered with clumps of *Sempervivum*, *Sedum*, and *Antirrhinum* would make a beautiful change as an interruption to the formality of beds and borders. But in planting a long border for effect, a systematic plan should be followed. Let us first determine how many and what kinds to have of showy *Phloxes*, *Delphiniums*, *Paonies*, *Pentstemons*, *Lilies*, *Tritomas*, and other plants that are distinct and striking, and mark off places on the border in order to repeat them all through. For example, if we have a border a hundred feet long, we may plant ten clumps of white *Lilies* at ten feet apart; midway between them, ten clumps of *Phloxes* ten feet apart—these to be nearly the same height, and selected for colour rather than form; midway between these, clumps of *Delphiniums* and *Aconites* of tall growth; and so on, filling in with all sorts of odd things of the same, or nearly the same, height. So in a line in advance of those, we may have ten clumps of herbaceous *Paonies* at ten feet apart; midway between them, ten clumps of *Dielytras*; and so on again, filling with odd things, of which one or two specimens are sufficient. These repetitions will have a fine effect in the season of flowering of each kind, and hard formality would be prevented by the admixture of all sorts of things with them; patches of scarlet *Lycnis*, dark red *Fraxinella*, yellow *Enotheras*, and so on. After one special display has waned another will follow, and the changes of the border will charm the possessor a thousand times more than the most elaborate bedding display, at only a thousandth part of the cost for a similar extent of ground. We might, indeed, match a line of *Alyssum saxatile*, glittering like gold, alternating with *Aubretia Campellii* and *Morei*, against the best geranium composition ever seen. Patches of *Campanula carpatia*, alternating in the same line as the last, give blue in autumn not to be surpassed for purity and depth; and *Campanula rotundifolia*, white and blue of such exquisite beauty in the summer as to render such a border a place of delightful resort for mere admiration of its colours or for quiet meditation.

Fruit Garden and Orchard House.

ORCHARD TREES may be better pruned now than later in the season, as the dead and dying branches can be easier discerned while the trees are still in leaf than when they are quite bare. There is no mystery as to the pruning of standard trees. Never lop off large branches if it can be avoided; their removal is a positive injury to the tree; never cut carelessly, or allow a bough to snap off when half sawn through. Remove a branch where two cross each other; remove those that screen the boughs below them from the sun; keep the heads of the trees open, so that every part is equally exposed to air and light; and remember all through that bearing trees very seldom grow too vigorously, or make wood where it is not wanted, and the less use of knife and saw the better.

PLANTING may proceed without regard to the leafiness of the trees. They will soon shake their leaves off after being lifted. If the operation is delayed, bad weather may render it impossible to plant until perhaps late next spring, and the trees will lose a period of four or five months in making roots in their new quarters. Every practical man can call to mind having lost the early period of the planting season, and having to wait till March or April following in consequence of rain, frost, snow, and other little incidents of the British winter.

Greenhouse and Conservatory.

CINERARIAS are growing freely, and must be encouraged by giving them a shift on, using a rich, light, fibrous soil. Do not put any in heat, and keep as many as possible for the present in cold pits. A few, however, may have a place on a shelf near the glass in the greenhouse for an early bloom. See that they get enough water.

VERBENAS must not go dust-dry, nor yet be made very wet. Do not encourage growth unless there are indications of mildew, in which case, if the plants are of any value for cutting from, put them in a good heat and propagate at once. This is better than tampering with mildew, for if it once acquires ascendancy among verbenas, it generally ends by killing them all off.

HEATHS are generally speaking so hardy that a good pit suits them as well as the greenhouse. Where they have to be mixed up with other plants, let it be borne in mind that they must have abundant ventilation, plenty of light, and only a moderate amount of water. The heath house at this season is rather dull. Give abundant ventilation, and avoid the use of fire-heat until the actual occurrence of frost.

MIGNONETTE sown now, and put in a heat of 70°, will soon make a start. Sow in rich light soil, in pots extra well drained. When the plants are up, thin them to three in a pot, and keep them in the greenhouse, where they will flower from the middle of February to the end of March, and be much valued. Any excess of moisture during winter quickly kills mignonette.

PELAGONIUMS must have all the light possible, and be kept almost dry, with plenty of air in fine weather.

FUCHSIAS must have fire-heat and weak manure-water to keep them in bloom. When fuchsias are allowed to go to rest, it is good to put them out of doors for a time, as the exposure promotes perfect ripening of the wood, and when housed under stages they will want no further attention till spring. Now that yearling plants are most encouraged at exhibitions, cultivators wish to know how best to produce fine specimens in a brief space of time. It is a question altogether of growing: they must be kept growing fast, with a humid atmosphere and a steady heat, and with occasional stopping and shifting on. The fuchsia can bear rough treatment, but it can also enjoy a life of luxury; and those cultivators who have not yet succeeded in producing good yearling plants are advised to try a higher temperature, with an increase of moisture to the roots and overhead.

TUBEROSES AS WINTER FLOWERS have been the subjects of a succession of experiments at Stoke Newington during several seasons past, and it is now an established fact that they may be made available to furnish winter flowers. Messrs. Barr and Sugden have supplied for the purpose bulbs of the several sizes and qualities known in the market, and one result of the experiments is to prove that the smallest and cheapest bulbs will not flower at all. Unlike hyacinths, the smallest bulbs of which produce flowers, the small tuberoso bulbs do not contain flowers, therefore cannot produce any. The practice with the heaviest selected bulbs has been to pot them in successive batches, and reserve for the latest supply of flowers the heaviest bulbs of all. Some are started in gentle bottom-heat in January, and flower beautifully in June; the large bulbs, measuring nearly two inches across, producing fine flowers, those an inch and a half produced flowers less fine, and a few of these fail to flower; the smaller bulbs produce leaves only. To buy such bulbs is to throw money away. So far good; we learnt definitely the cause of the failure so often complained of by our readers, but that was not sufficient. We reflected that tuberoses would be valuable from October to Christmas, or later, whereas in June there are so many flowers that we are not much in need of them. So we keep back a large lot of each of the several sizes, and have them potted the first week in April, in a mixture consisting of equal parts old dung, loam, and leaf soil, with a half part of silver sand added. The soil is nearly dry, and no water given. The pots are all placed on the path of a Paxtonian house, and they have a little water during the six weeks they remain there, but enough only to moderately moisten the soil; generally speaking, they are nearly dust-dry during the six weeks they remain there. Then they begin to show little green points at the crown of each bulb, which is a proof they are growing. They are then placed high up on a shelf to benefit by the heat of the sun acting on the pots, and have water twice a week. By the middle of June they are growing freely; they are then removed from the shelf and stood on inverted pots on the bed of the house full in the sun, and have plenty of water. By the middle of August the flower-spikes of all the large bulbs are pushing freely, and towards the end of September many of them are showing the white of their flowers, the spikes being three feet high; others are about half grown. The next point of importance is to prevent them being injured by cold, for a certain degree of warmth is necessary to induce the flowers to open. We now put a few at a time into a warm house to expand the flowers nicely, and if the weather should become too cold for those still advancing, the Paxtonian house must have the benefit of a little warmth from the hot-water pipes. Thus it is proved that they may be flowered in autumn without bottom-heat, and that the only way to be sure of bloom is to obtain the largest bulbs. Since these various experiments we have referred to several essays on tuberoso culture, and are bound to say that, with very few exceptions, what books say on the subject is sheer nonsense. We are now enjoying the rich spicy perfume of freshly cut flowers of tuberoses, and should have no difficulty in commanding a supply till Christmas.

Forcing Pit.

CUCUMBERS for winter fruiting must be kept growing freely with a steady heat. Damping and mildew are the plagues that trouble young cultivators at this time of year. Both may be prevented by affording sufficient heat, and carefully regulating the degree of atmospheric moisture. If mildew appears, apply dustings of sulphur immediately. If the plants show fruit before they are strong enough to bear, nip the fruit out.

MUSHROOMS.—Beds made now will begin to produce at a time when the fruit will be much valued. Let the stuff be beaten firm in making up the bed; make a large bed in preference to a small one, and have it four feet deep if possible; mix turfy loam with the dung, both to moderate the heat and secure a longer state of bearing; do not spawn the bed till the heat has declined to a moderate point, and take care from first to last that the bed is never too wet and never too dry. For other matters in this practice refer back, and abundance of information will be found.

PEACH-TREES in the early house must be pruned at once, and the house must be rendered clean before starting them. Begin gently, to allow of a steady increase of heat, and take care the border is moist enough in the first instance.

VINES.—Grapes intended to hang must be well aired, and the house must be kept dry. Generally, various plants are kept under vines, and these want more or less water, and the humidity occasioned thereby causes the grapes to rot. Gardeners are too often expected to perform impossibilities in the keeping of ripe grapes. All that can be done where there are plants is to watch for fine mornings to give water, and occasionally to let things go drier than is good for them, and to use a little fire-heat so as to allow of ventilation and dry the atmosphere. When vines are at rest the loose bark should be taken off and burnt.

FROS carrying a second crop are often a cause of some anxiety. The larger the fruit the less likely is it to survive the winter, and the best way to save some is to remove all that are larger than peas, and then mat up the trees loosely, so that there will be a circulation of air amongst the wood to keep it hard, yet so that in the event of cutting winds they will have a fair amount of shelter.

SQUASHING HIM.—Sheridan used to be annoyed by a silent Member who would interrupt him constantly with "Hear, hear," *usque ad*. One night he took an opportunity to allude to a well-known political character of the time, who wished to play the rogue, but had only sense enough to play the fool. "Where shall we find a more foolish knave or a more knavish fool than this?" "Hear, hear!" was instantly bellowed from the accustom'd bench. The wicked wit bowed, thanked the gentleman for his ready reply to the question, and sat down.

Correspondence.

PHILIP MILLER ON THE GLADIOLUS.—An old folio volume last week came into my possession: "The Gardener's Dictionary: adorned with copper-plates, by Philip Miller, gardener to the Botanick Garden at Chelsea, and F.R.S. 1731." Some of the articles are very interesting. As a specimen, I have transcribed the one on the Gladiolus, which I thought might amuse your readers. Do you know whether this work is scarce? My copy is beautifully printed, and in excellent preservation. W. D. SUTTON.

[It is not at all scarce, being frequently entered in the catalogues of the second-hand booksellers.]

"Gladiolus (takes its name of Gladius, Lat., a sword, g. d. little sword, because the leaves of this plant resemble a sword), Corn-Flag. The characters are: It hath a fleshy, double, tubercose root; the leaves are like those of the Flower-de-Luce; the flower consists of one leaf, and is shaped like a lily, spreading open at the top into two lips, the upper one being imbricated, and the under one divided into five segments; the ovary becomes an oblong fruit, divided into three cells, which are filled with roundish seeds wrapt up in a cover. The species are:—1. Gladiolus; utrinque floridus; corn-flag, with flowers on both sides the stalks. 2. Gladiolus; carnei coloris; flesh-coloured corn-flag. 3. Gladiolus; floribus uno versu dispositis, major, floris colore purpureo-rubente; great corn-flag, with reddish-purple flowers ranged on one side the stalk. 4. Gladiolus; major Byzantinus; great corn-flag of Constantinople. 5. Gladiolus; utrinque floridus, floribus albis; corn-flag, with white flowers ranged on each side the stalk. 6. Gladiolus; maximus, Indicus; the largest Indian corn-flag. There are some other varieties of this plant which are preserved in some curious botanick gardens, but these here mentioned are what I have observed in the English gardens. These are all propagated by their tuberoso roots, which the first, second, and third sorts produce in great plenty, so that in a few years, if they are suffered to remain unremoved, they will spread very far, and are hardly to be entirely rooted out when they have once gotten possession of the ground. These roots are in shape very like those of the large yellow spring crocus, but are somewhat bigger, yellower within, and have a rougher coat or covering. The small offsets of these roots will produce flowers the second year, therefore when the old roots are transplanted, the offsets should be taken off from them, and planted into a nursery bed for one year, by which time they will be fit to transplant into the borders of the pleasure-garden. These roots may be taken up in July, when their leaves decay, and may be kept out of the ground until October, at which time they should be planted into the borders of the pleasure-garden, intermixing them amongst other bulbous-rooted plants. But if you plant them in large borders in wilderness work (where they will thrive and flower very well), they need not be transplanted oftener than every other, or once in three years; whereas in borders of a pleasure-garden, if they were suffered to remain so long, they would overrun the ground, and be very troublesome. The third and fourth sorts are the most valuable, producing taller stalks and fairer flowers; nor are these so apt to increase, which renders them fitter for the borders of a flower-garden; so that since these have been introduced and become common, the other sorts have been rejected, unless in some old gardens, or for large wilderness quarters, where they will grow better than the two last mentioned. These plants may also be propagated by seeds, which should be sown in pots or tubs of light fresh earth soon after they are ripe. These tubs should be placed where they may enjoy the morning sun until eleven o'clock, in which position they should remain until October; at which time they must be removed where they may have the sun during the winter season, and the March following the young plants will begin to appear; at which time the boxes or pots should have a little fine earth sifted over the surface of the ground, and be removed again where they may have only the morning sun, observing during the time of their growth to refresh them with water in dry weather, as also to keep them clear from weeds. The Michaelmas following, if the plants are very thick in the pots or boxes, you should prepare a bed or two of fresh light earth, in proportion to the quantity of your young plants, and after levelling the surface very even you should spread the earth of the pots in which the roots are contained as equal as possible upon the beds (for the roots at this time will be too small to be easily taken up), covering the bed about half an inch thick with light sifted earth, and the spring following, when the plants begin to come up, you must stir the ground upon the surface to loosen it, and carefully clear the beds from weeds. In these beds they may remain (observing in autumn to sift some fresh earth over the surface) until the fourth year, by which time they will begin to show their flowers; therefore you may now observe to mark out as the best kinds as they blow, which may the succeeding year be transplanted into the pleasure-garden, but the poorer kinds should be thrown away all not worth preserving, for the good sorts will soon multiply and furnish you with a sufficient stock from offsets. The Indian Corn-Flag is tender, and must be preserved in a warm greenhouse or a moderate stove during the winter season. These roots should be planted in pots filled with a light sandy soil. The best time to transplant them is any time from May, at which time their green leaves decay, until September, that they begin to shoot again; and in October the pots should be removed into the greenhouse; and during their season of growth, which is chiefly in winter, they must be frequently watered, but you must not give it them in large quantities; but during the summer season, if they are suffered to remain in the pots, they should have little moisture, but only be removed to a shady place, for much wet at the time their roots are inactive is apt to rot them. This plant but rarely flowers with us, but when it doth it makes a beautiful appearance in the greenhouse, especially coming in January, when few other flowers appear, which renders it worthy of a place in every curious garden."

CATALOGUES.

EUGENE VERDIER FILS AINE, 3, RUE DUNOIS, GARE D'IVRY, PARIS. *List of New Roses for the season 1867-68.*—A lengthy list, the contents of which will have immediate attention in these columns. English rosarians are referred to Messrs. Betham and Blackith, of Cox's Quay, Lower Thames Street, London, as the agents for M. E. Verdier.—*Trade Catalogue of Gladioli, Paeonies, and New Roses, 1867-68.*—M. Souchet's gladioli are here, those now let out for the first time numbering twenty-five varieties.

JABEZ J. CHATER, GONVILLE NURSERIES, CAMBRIDGE. *General Descriptive Catalogue, 1867-68.*—This contains a good selection of herbaceous and alpine plants, Dutch and Cape bulbs, a remarkable collection of pelargoniums of the large-flowering, zonal, and other sections, a good selection of roses, and all the other several classes proper to a general catalogue, inclusive of hollyhocks, for which the Chaters have long been famous.

Replies to Queries.

Eugenia ugni.—R. II.—This plant requires the same treatment as a myrtle, —a good rich loam, rather liberal pot-room, plenty of water when growing, and a rather shady place in a cool greenhouse, except during July and August, when it is better out of doors in a rather shady place. The tree is nearly hardy, but is quite unequal to our severest winters.

S. B.—Hays's Constant stove will answer admirably for your small house.

A Bee.—No Ipomea can be taken into consideration as a substitute for ivy. In making the ivy border, dig deep, add manure if the soil is at all poor, and plant strong established plants. You may obtain plants five or more feet high, well furnished, from any good nursery, and when these are planted and pegged down a good border is formed at once. For information on Moule's Earth Closets, write to Mr. Evans, 29, Bedford Street, Covent Garden, W.C.

Young Gardener.—Your heliotrope was shrivelled almost to dust, so we can give no opinion of its merits.

Gloxinias.—Subscriber.—Yours have gone wrong through being too cold. The white worms about the hyacinth bulbs are probably owing to the decay of the bulbs. Probably they were damaged bulbs in the first instance, and in the second have been kept too wet.

R. J. W.—Joyce's stove will not hurt the plants, but in the event of very severe weather we should doubt if one would suffice for a house 30 feet by 10 ft. Such a house should be heated with a small boiler and 3-inch pipes.

J. W., Whitby.—It will do no good to give the vines fire-heat now. When the leaves are down, cut them back, so as to leave only one bud of the new growth on each. Surely your border must be very faulty to account for so poor a growth.

G. B. P., Cottingham.—The leaves of "Lucy Grieve" and Lady Cullum sent are remarkable examples of colouring. The leaf of Lady Cullum is particularly rich, the disk being only half green, so that the green constitutes only about one-seventh of the entire leaf, the remainder being a rich gold-yellow with a broad unbroken zone of brilliant carmine-scarlet. Plants well furnished with such leaves are calculated to take one's breath away.

E. G. Henderson and Son.—Your double-flowering pelargonium, "Prince of Novelties," is exceedingly rich, and a most pleasing flower. Their thorough doubleness must render the flowers long-lasting and extremely showy on the plant, though so dreadful a violation of the orthodox properties.

Old Subscriber.—We cannot inform you where to apply for Hays's Constant Stove; it appears that the agent has gone, leaving no address.

W. B. B.—You may force the strawberries in the vinery admirably. Give them a shift at once, and they will fill their new pots with roots before you take them in to force.

P. Q.—The person you inquire about grows for sale, and sells what he grows.

THE PEAR AND ITS PARASITE.

Frequently during the last few weeks we have had complaints from correspondents and others with regard to the injured condition of the foliage of pyramidal and other pear-trees. In some instances the trees are said to look as if the leaves were dried up or scorched; in others they are browned with rusty-looking spots. In some cases injury takes place to such an extent that numbers of the leaves die off, and leave the trees partially defoliated. Some, satisfied to note effects without taking thought or pains to look for causes, attribute this to "hlight"—a very general term, always at hand, and too often a stumbling-block in the way of that close observation and inquiry so necessary and so useful in matters of this kind. Others more observant, rightly attribute the evil to the voracity of what they call small black leeches or slugs found on the leaves, and as these appear in greater numbers and carry on their depredations more vigorously in close showery weather, some have gravely assured us they are brought down with the rain! Well, the pest in this case is neither atmospheric nor pluvial but the leech, or rather tadpole-like larva of one of the saw-flies—Tenthredinidae. In the larva state it is familiarly known as the slimy grub of the pear. The perfect insect is known to entomologists as *Tenthredo* or *Selandria Aethiops*, or black-winged pear saw-fly. For the benefit of those of our readers who may be interested in detecting these destructive little leaf eaters, and checking their ravages another season, but may have failed to pay any particular attention to them during their period of activity during the past weeks, we give a few descriptive particulars. When at its full size the grub or larva is about half an inch long, the body slender and tapering, the head in appearance proportionately very large and tadpole-like. We say in appearance; for it is not exactly the head is so large, but the little creature has the power of inflating and expanding over the head the thoracic or upper segments. On the belly or under side it has numerous feet—about a score; the colour dirty yellow; the upper portion black or nearly so; the entire surface is covered with a slimy secretion, whence the popular designation. During the day they remain at rest on the leaves, but towards its close, more especially if it be after rain or a moist evening, they may be seen actively at work on the upper surface of the leaves. When feeding, they remain in the same spot until they have devoured every portion of the upper surface, and the underlying green portion, or parenchyma, within reach, leaving the cuticle of the opposite side of the leaf untouched and transparent as an eye-glass. When this slaying and fleshing of the leaves is carried on uninterruptedly, and with the extraordinary dispatch which characterizes the operations of these pests, our readers can well understand the permanent injury it will do the trees, apart from that to the fruit-crop of the current year, and from the unhappy scorched look of the foliage. About the middle, or towards the end of the present month, the larvae spin and encase themselves in their cocoons, and bury themselves in the soil, where they remain dormant for about ten months, the fly or perfect insect emerging into active life about midsummer following. The female insect deposits her ova on the upper surface of the leaves, and in a very few days the larvae are hatched, and these tiny but most destructive enemies of our pretty pyramidal commence operations. With regard to the remedies for the pest, syringing the trees with lime-water, or dredging the leaves with powdered caustic lime, are sometimes, but not always, efficacious. Hand picking and destroying them may be a little tedious, but it is effectual. Instead of applying remedies to actual disease, it is always better, if possible, to prevent it, and in this case it might be done to a great extent if pear-growers were able to recognize the perfect insect and its ova, and have recourse to means for destroying the one or removing the other.—*Irish Farmer's Gazette.*

The Gardener's Magazine.

SATURDAY, OCTOBER 26, 1867.

EXHIBITIONS OF SEVERAL DAYS' CONTINUANCE have become the rule in those cases where great gatherings of horticultural productions are attempted. From the financial point of view, the long-continued shows are eminently desirable. The monetary success of the International of 1866 was the result of the extension of the time beyond the term originally determined on. The great shows at Edinburgh, Manchester, and Kensington, of late years, have apparently succeeded solely because time was afforded for success; and we may take the converse view, and say that failure in respect to fiscal returns at exhibitions of only one day's duration is owing to the want of time to gather in the money. It matters not how much may be expended on advertising, and however energetic the promoters may be in giving publicity to their proceedings and intentions, a large portion of the public never know of anything until it has become notorious; and a flower show, if good of its kind, and reasonable, appears to increase in popularity and attractiveness just in proportion as the flowers fade and the plants lose their freshness and beauty. There exists a class—created for some wise purpose no doubt—who never go anywhere until everybody else has been; and as the promoters of exhibitions wish especially to benefit that class, and to receive in return their acknowledgments, exhibitions designed on a great scale must be kept open more than one day. Wealthy societies may be well able to adhere to the one-day system, but a great appeal to the general public requires more time to bring forth its fruit, and we must expect the extension system to triumph over the restriction system, in respect of horticultural exhibitions as in the cultivation of grape-vines. As a rule, financial success satisfies all parties, and it cannot be denied that money is a potent lever in moving the horticultural world.

But the convenience of the sight-seer and the consideration of monetary returns are not the only points involved in the consideration of this subject. The exhibitor is an important personage. If he suffers many inconveniences, and if his plants suffer by too long absence from home, long-continued exhibitions must be deprecated by the horticulturist in exact proportion as they are appreciated by the public. Without plants and flowers there cannot be much success; it is not the announcement of a show which brings the money, it is the fact that a show is in existence, and the interests of the exhibitor must therefore be taken into account. Now it must be obvious to those who know nothing practically of the carrying out of an exhibition, that exhibitors are severely taxed when their contributions are detained several days in place of one, and that there is great risk of injury to the plants. At an exhibition of only one day's duration, the exhibitors and their assistants remain in readiness to remove their goods the moment they can be liberated; but in many cases of long-continued shows, they must be left entirely without special protection, and many of the exhibitors must make long journeys twice over, and devote twice as much time to the affair as in the other case. As to the plants, those that are of tender constitution must suffer more or less in a draughty tent, where the temperature is far below what they are accustomed to, and their value at the close of the show must oftentimes be considerably less than it was at the beginning. The problem for promoters is to reconcile these difficulties with the advantages that result from the extension of the time, and on the solution of the problem rests the prospects of success in the future.

One of the first essentials is to give the exhibitor a due share of the benefits resulting from the enlarged period of the exhibition. Prize-lists must be liberal, and there seems to be wanted some more certain way of rewarding merit than the customary award of first, second, and third prizes. It is hard upon a man who takes a fine collection of plants a distance of many miles, who leaves his plants to do well or ill as the case may be, and who is compelled to make two long journeys, or else sacrifice several days on the spot looking after his plants, and who loses the third place by just a point or two, and obtains nothing at all to compensate him. But in some cases, as at the Crystal Palace and Kensington, the winners get so little, that it is a matter of constant surprise to those who are

familiar with the costliness of exhibiting, that at those places flower shows are possible at all. It is true that trade exhibitors think less of winnings than of publicity, and every honour gained is for them an advertisement. But the private cultivator looks at the matter from another point of view: to him honour is the more acceptable if accompanied with a substantial reward, and a larger scale of prizes than that which prevails is essential to the success of long-continued exhibitions. Then as to the plants: cultivators of orchids and other delicate habited stove plants must be assured of a better protection for their pets than canvas. It is not at all an uncommon thing to see valuable plants almost blown away before the termination of an exhibition, and such an event is surely to be deplored. Owners of valuable plants are not likely to expose them frequently to the risk of injury, and it should be the aim of promoters of exhibitions to remove every possible objection to the contribution of the most valuable subjects, or great flower shows must become great gatherings of things belonging to the category of commonplaces. The International Exhibition of 1866 afforded a fine example in this respect, in the heated "annexe," wherein the orchids were staged. Such a building cannot be provided on every occasion of a three or four days' meeting, but something approximating thereto is needful, if only a better sort of tent than such as is commonly used. These are matters which lie at the very foundation of success in the management of great exhibitions, and they must have practical consideration, or great exhibitions must come to an end.

HULLETT'S CHINESE GRASS, which was to supply us with a fabulous abundance of bread of far better quality than wheat bread, and afford a valuable fodder for cattle, and materials for wine and sugar from the juices of its stems, has proved exactly the sort of mare's nest we predicted it would,

SORGHUM TARTARICUM (so-called).

when the nine thousand correspondents of Mr. Hullett were beseeching him for seeds. Subjoined is a figure of a tuft selected from several which have been grown at Stoke Newington. The tuft figured is one of the commonest varieties of Sorghum, the one that was ushered into public notice a few

years ago, as *S. saccharatum*, as a valuable fodder plant, but which has never acquired a fixed place in the round of farming operations. Other samples have resolved themselves into the well-known *Andropogon sorghum*, and several other samples never vegetated at all; so it is impossible to say what they were—most likely the seeds were dead. So far as we know, no one within the boundaries of Britain has harvested a handful of ripe corn from any of the seeds that were given or sold in the past spring. Mr. Hullett no doubt meant well, while he knew little. That is a kind view to take of his part in the business, and we make him a present of the kindness. But for those members of the trade who profess to be the heads of "respectable" houses we entertain a quite different feeling. We doubt if they meant well; and if they knew little, they were bound to learn before puffing a thing of this sort. The probability is that they knew much—perhaps too much.

THE GARDENS OF SHAKESPEARE.—Mr. T. O. Halliwell writes to the *Times* as follows: "Four years ago, the gardens of Shakespeare being in danger, and no person of influence coming forward, I ventured to solicit your aid in saving them from the hands of the builders. It was mainly owing to the great prominence given to the subject in *The Times* that a large sum was subscribed, and the site of New Place, with the greater part of the gardens originally attached to it, purchased for £3,400. Since then the very interesting remains of the poet's residence have been discovered and exposed to view. A small but important portion of the gardens, which will cost at the lowest estimate £800, still remains to be secured; in addition to which a considerable sum is required for putting them into order, and for a large extent of outside fence. At least £1,200 is necessary for these objects. I am not in a position to give much more than my time, but I will gladly advance a quarter of the sum, £300, on the chance of being repaid in the future, if the remaining £900 be subscribed; or I will give £100 if eleven others will do the same. If it be added that nothing is allowed for salaries, personal expenses, &c., it is merely to justify the liberality of the public and your kind sanction. In fact, the only extraneous expenditure will be upon a promised memorial in the ground recording the names of all donors of £100 and upwards."

THE VICEROY OF EGYPT'S VISIT TO ENGLAND.—Mr. William Bull, of the Establishment for New and Rare Plants, King's Road, Chelsea, writes to us as follows: "It occurs to me that it may be worth recording, as an instance of the effect on foreign potentates of horticulture as carried out in England, that the Viceroy of Egypt, when recently here, was so struck with it, and the plants and flowers he saw, that I have received a commission to send him out a thoroughly proficient flower gardener; one capable of carrying out horticulture in a similar manner to the style adopted in this country. As is generally known, the Viceroy already has an English gardener; but the one I am sending out goes exclusively for the cultivation of flowers, a new and entirely separate appointment, brought about by the Viceroy's last visit to this country."

MONSTER PEARS.—There were exhibited in the shop of Messrs. Le Cornu, seedsmen, St. Helier's, Jersey, last week, four pears which for size and splendour excelled everything of the kind hitherto known in Jersey, renowned as that island is for the quality of its pears. These four specimens weighed respectively 19½, 21½, 24½, and 30½ oz., making the almost incredible total weight of 96¼ oz.! The three first-mentioned, weighing 65¾ oz., had grown on a single eye. They are of the far-famed species known as Chaumontelle, which is peculiar to Jersey, and were grown in the grounds of Mr. G. H. Horman, her Majesty's Solicitor-General for the Island of Jersey.

COWPER'S SUMMER-HOUSE AT OLNEY.—A movement has been set on foot for the restoration of Cowper's summer-house at Olney, and from the way in which the proposal has been met by persons acquainted with the matter in all its bearings, the proposal appears to savour of both Vandalism and jobbery. Mr. Collingridge, of the *City Press*, writes to a daily paper as follows:—"Correspondents have over-estimated the value of the names pencilled on the walls of the summer-house at Olney. Some of them are, it is true, 'familiar in our mouths as household words,' but I am very doubtful if all these are genuine, while the majority are unknown to fame, and many are undoubtedly of the class referred to by Cowper, when speaking of the alcove. He says:—

Not all its pride secures
The grand retreat from injuries impress'd
By rural carvers, who with knives deface
The panels, leaving an obscure rude name,
In characters uncouth, and spelt amiss.

There are, no doubt, some autographs that are worth preserving, but it is obvious that to restore the summer-house, which is only a lath-and-plaster erection, in the way that has been suggested, would very effectually get rid of all these signatures at a stroke. Nor is this renovation really needed. The late Mr. Anthony Morris, who held that part of the garden containing the summer-house (which was divided many years since from the dwelling-house, in which, in all probability, most of Cowper's productions were penned), took a just pride in keeping it in good order; and having been to Olney during the past month, I can testify to the fact that it is far from being in the ruinous condition that might be imagined from the statements made respecting it. If, however, it is thought desirable to raise a memorial to Cowper—and I as an 'Olney boy' certainly think so—why should not the suggestion thrown out some time since be adopted, and a memorial hall be erected? Places that are identified in any way with celebrated men generally have something to show for the fact; and why should the town where 'Newton preached and Cowper sang' be worse off in this respect than others similarly situated? The inhabitants of Olney are not deficient in public spirit; and as the Earl of Dartmouth, who is lord of the manor, has made a good start by offering £100, I venture to hope that ere long something tangible will be accomplished. The vicar and the ministers of the Independent and Baptist chapels would, I feel sure, be found quite ready to co-operate, and I would suggest that any one wishing to aid in the work would do well to communicate with those gentlemen. Mr. Osborn, the present occupier of the garden in which the summer-house stands, and Mr. John Sleath, the occupier of 'Cowper's house,' are at all times most obliging in their attention to visitors who may be desirous of seeing these classic spots."

THE THOMPSON TESTIMONIAL progresses in a more promising manner than heretofore. Many head-gardeners have acted on the suggestion we made on the 28th of September last, and have sent in, with their own subscriptions, gatherings from their foremen, assistants, and the garden lads; so that the half-crowns and shillings are beginning to appear. There are 70,000 gardeners in Great Britain, and if these all contributed one shilling each, the total would be £3,500. Then how many

lady and gentleman amateurs are there who owe Mr. Thompson five to ten pounds each for the part he has done to advance the art of horticulture to its present enjoyable perfection! Here is an undeveloped million no doubt—not wholly undeveloped either, for many who read this amongst persons of good means will at once, pleased with the reminder, send off their one, two, or three guineas, and many more will gladly contribute half a guinea each. An opportunity of this kind is not likely to occur again to the present generation, for there is scarcely a horticulturist living save and except Mr. Thompson, forty years superintendent at Chiswick, for whom the press could unite in its appeals without coldness anywhere, and without the shadow of unseemly rivalry or party spirit. Mr. Thompson's labours have secured for him this universal testimony of esteem and this common sympathy. Surely the testimonial ought for the same reason to move briskly and swell rapidly, and become a matter for general congratulation and rejoicing.

AN ASTONISHING TREE.—A Williams's Bon Chrétien pear-tree, in the garden of William Sharp, a working gardener in Arundel, has, he informs us, borne four crops this year. The first crop was gathered at the beginning of September, and the pears were of the size that fruit of this description usually are; the second was gathered on the 13th inst., being about two-thirds as large as the first; the third and fourth crops are still growing, and are respectively of the size of walnuts and filberts. There was rather more than a month between the budding of each crop, and when the first was gathered the fourth was in flower. With the view, if possible, of accounting for this phenomenon, he will be pleased for any one to examine the tree.—*West Sussex Gazette*.

MESSRS. CLAUDET AND HOUGHTON, of 89, High Holborn, London, have engaged to cater *in extenso* for cultivators and exhibitors of plants and flowers who require elegant receptacles in glass or porcelain. They have given a new character to "Tye's hyacinth glasses," by adopting a series of original and exquisitely beautiful embellishments, and they have prepared an almost endless variety of patterns of épergnes, bouquet-holders, Marchian vases, &c. In fern-cases and aquaria they appear to be as busy as in smaller and more fanciful articles. Therefore, we can with pleasure refer to them any of our friends who may be in want or difficulty in respect of such things.

EXTENSIVE KNOWLEDGE.—In a letter which appears in the *Daily Telegraph* of Tuesday last, Mr. George Cruikshank declares the mineral waters of Buxton and Harrogate "of far more power and benefit than any others in the universe."

AVICIDE IN A NEW SHAPE is practised by Frenchmen on the coasts of the Mediterranean. They spread nets for the swallows when they are on the way southward in their migration, and catch thousands of them when they come down to rest before taking the long passage of the sea. They catch them to cook them and eat them as choice delicacies! If Peris were to wing their way near the omniverous Gaul, he would look for his peashooter, in hope of winging a seraph and eating it on toast. But let us have patience; Frenchmen will take to eating rats, mice, moles, and centipedes ere long, and the passion for universal appropriation of everything digestible may prove in the end as useful as for the present, and especially in the eating of robins and swallows, it is abhorrent to right feeling and injurious to mankind. Swallows, in common with other small birds, have been scarce of late years; if the French follow their new and childish pursuit, perhaps we may lose the swallows altogether.

WALL FRUIT, AND HOW TO GROW IT.

By J. R. SCOTT, Esq.

The extreme variability of our climate, as exemplified in the summer season of the past year (1866),* has brought prominently to the attention of pomologists the necessity of guarding against the effects of the constant change to which the British climate is exposed, and its prejudicial influence in the growth and maturation of fruits the denizens of warmer latitudes than our own.

The full effects of a warm climate, mainly the result of absence from excessive moisture, have during the three preceding years, 1863-4-5, been fully exemplified by the promotion during those seasons of that which is very rare in this country—viz., of three successive abundant fruit crops, and crops in which fruit has attained a greater degree of perfection and flavour than is consistent with the usual climacteric conditions of Great Britain.

During the seasons above referred to, when the rainfall, taking one year with another, was considerably below the average, the maturation of the peach and apricot, and the ripening to perfection of the French and Belgian pears, were attained without difficulty in England south of the Trent; and this simply from the fact that the summer and winter seasons were, from the absence of excessive moisture, warmer in the mean by four or five degrees than the geographical position of the country would lead us to expect, by reference to the statistics of former years.

As all things in nature find their balance, thus hot seasons are counter-balanced by cold ones; seasons of excessive drought by those of extreme moisture. The moisture by evaporation producing cold, and the absence of moisture and evaporation inducing heat and dryness of the atmosphere, these in their turn producing a clearness of sky and preponderance of sun, with its beneficial effects of light and heat on all living things.

In these reflections there is nothing new; a few words may, however, be said as to the results produced by the variability of the climate of England, and the manner in which its more prejudicial effect on the cultivation of fruits of a warmer and more congenial climate may be ameliorated or prevented altogether.

Amongst the fruits indigenous to this country are the apple, pear, plum, cherry. The wild varieties of these may be found in every part of England, and the climate has little effect upon them, the cultivated kinds, however—the denizens of our gardens, descendants for the most part of varieties imported by the monks and carefully nursed in monasteries and the gardens of the wealthy in bygone times—are constitutionally more delicate, and require a warmer and drier climate than England usually possesses, to bring them altogether to perfection without artificial appliances beyond the reach of the millon; the effect of this, as shown in the deterioration through the unsuitability of climate, is particularly noticeable in the Ribston pippin and the old Golden pippin, which, with all the stimulus of increased knowledge in

* This paper was written in the spring of 1867, and was intended chiefly to explain the uses and advantages of "Scott's Glass Walls," which have been brought under public notice by the St. Francis Iron Work Company. The author's well-known ability and experience in fruit-culture afford sufficient reason, we think, for the insertion of the essay in the pages of the Magazine.—Ed.

cultivation combined with modern improvements in drainage, are far short both in size and flavour of those apples of our younger days. As the fruits named, together with the bergamots and the jargonelles amongst pears, are exhibiting yearly in their decadence the effect of climate upon them (after an existence in our gardens approaching to a century), so in their turn will each successive generation of the best varieties of our fruits now in cultivation deteriorate year by year, unless that deterioration be averted by artificial or other means; the same principle, viz., the effect of our climate on the cultivation of exotic fruits, is being felt, and will eventually prevail, as in the case of the potato, which, although acclimatized to a certain extent, would soon die out in this country if not preserved by superior cultivation.

The peach and its first cousins, the nectarine and the apricot, are foreign to this country; and although it is difficult with certainty to state from whence the peach was originally imported,—some maintaining that it is a Persian fruit, others that it is simply a cultivated form of the Jordan almond, to which botanically it is doubtlessly allied—yet, at all events, we are justified in saying that, save in the most exceptional of seasons, and under conditions quite as exceptional, it is only once in every ten or twelve years that we can fairly see in this country, in the open air, that most delicious of fruits in a state bordering on perfection.

As these fruits attain a perfection only in countries the mean temperature of which is five or six degrees warmer than the south of England—say in the south of France, on the northern shores of the Mediterranean, and in New York, where, in addition to the air being warmer, a less degree of moisture prevails, and it may be borne in mind that every geographical degree southwards represents one degree of heat—so only can these fruits be brought to the same degree of excellency here, and maintained without deterioration in a prolific and healthy state, by assimilating the climate of this country to that in which they are found to flourish by artificial if not by natural means.

The writer has given this subject great attention, and has endeavoured by means of drainage and by the best of cultivation and attention to counteract the effects of climate altogether, but has hitherto failed in producing more than a partial effect, altogether incommensurate with the trouble and expense to attain it; and it was not until he determined to cover in an old garden wall of 250 feet in length (against which grew sixteen peach and nectarine trees) with glass, secured in iron rafters so constructed that they could be removable at pleasure, that he was conscious in one season of the immense superiority of this plan over his neighbours', from securing a crop of magnificent fruit, nearly 1,200 in number, and which, if he had taken the precaution to assist with a single flow and return hot-water pipe, and by its means to ripen the fruit some twelve or fourteen days earlier than he did, he might have anticipated the arrival in the London market of the fruit from the south of France, and thus have paid in one season the cost of covering his wall with glass.

In no structure of glass, whether the trees are in pots or planted in the open ground, is the flavour of the peach, or its size, at all comparable with those trained to a wall and covered with glass. The result is due to the large amount of latent heat that radiates night and day from a brick wall, and to the protection and support afforded, for which the peach and its kindred allies, the apricot, the nectarine, and greengage, have an especial liking.

THE CHRYSANTHEMUM AS AN EXHIBITION AND DECORATIVE PLANT.

A flower garden is, of all the luxuries that mankind enjoy, the most pure and elevating, for it presents us with each varying season a constant change of forms and colours, eye, and of sights and sounds. The first buds and opening flowers of spring have a fascinating charm, and, ere the summer months have advanced upon us, all nature is clothed with a robe of gaiety; but with the return of autumn, how enriching are the many-coloured hues of the now changing foliage of the trees! their soft but mellow tints afford a feast to the beholder. As for the winter, it is not quite devoid of its floral attractions, for wherever there is a glass structure erected, there is, even in the most dreary months of the year, some variety of plants in bloom. With these remarks we introduce a few notes respecting the history of Chrysanthemum Exhibitions, and the mode practised at the present period, with the object of attaining large and superb blooms both for exhibition and home decoration.

The Stoke Newington Chrysanthemum Society claims, I believe, to be the parent of the many societies that have been originated within the last few years, and I think they may be truly proud of their offspring; for they have provoked such a laudable spirit of emulation wherever they have been established, as to gain for the Chrysanthemum a higher state of cultivation, and that too in gardens where they do not grow for exhibition. But to say that attention was not given to the production of large single blooms of this favourite autumn flower previous to the formation of the Stoke Newington Society, would be to detract from the merits due to other growers; for I can remember Mr. Widnall, a nurseryman then at Cambridge, exhibiting at one of those then popular autumn meetings of the South London Horticultural Society, a box consisting of single blooms of the then many leading varieties in cultivation, and I am satisfied the same would not now disgrace an exhibition table. On that occasion various were the conjectures among the gardeners present as to the means by which such fine blooms were obtained. Some attributed them to the soil, others to the atmosphere, and so on. But there can be no question but Mr. Widnall, who at that period was a very extensive grower of dahlias, both for sale and exhibition, had adopted the same system as that pursued for procuring large blooms of the dahlia, viz., that of thinning the buds and liberal feeding. However, as I was present at the first and second exhibition of the Stoke Newington Exhibition, I can say that, at that stage of the society's existence, they had not equalled Mr. Widnall's flowers, though they very soon afterwards made such marvellous strides in their cultivation as led to the production of those monstrous blooms, which were the wonder of crowds of gardeners, and others interested in horticulture, who were attracted to their annual exhibition, from various distant parts of the metropolis and the country. The result of these annual visits was that numbers of them returned not only pleased, but instructed. This then led to their originating societies in their own localities; thus the number of visitors to the parent society from a distance gradually decreased with each returning exhibition. But, notwithstanding all these deductions from the interest now felt in the Stoke Newington Society, I believe I am not exaggerating when I say that no other society that has hitherto been formed has ever brought together such a number of competitors at one time as they have, especially in the classes devoted to cut blooms. It might be perhaps considered invidious on my part to enumerate some from the long list of names of those who have been foremost in this field of honourable rivalry,

but I cannot avoid repeating those of Messrs. Tait, James, Crockford, Merry, Shields, Taylor, Scruby, Holmes, and Argent; these with others were instrumental in promoting its prosperity, and though the most of them are no longer active members, I anticipate there will be nothing lacking to make its twenty-first anniversary, next month, as interesting as any of its preceding exhibitions. But for those who are anxious to see the Chrysanthemum previous to its being placed on the exhibition table, it would be neither time nor money mispent for them to visit the collection of Mr. Forsyth, nurseryman, of Stoke Newington. There is perhaps no other grower for sale who has devoted so much space and time to producing superior growth and flowers. Others may exceed him in numbers of varieties, but not in quality of bloom and size of plants. A few hours spent in viewing this collection would, to an acute observer desirous of excelling in their cultivation, be a profitable lesson, far exceeding in value a season of individual experience. Mr. Forsyth is not actuated by a selfish spirit, for he is very communicative in reply to all inquiries respecting their treatment, of which his catalogue presents a striking example, for, in addition to the usual details of a list, it contains a concise treatise on their general culture.

To those who as yet are but novices in the art of preparing and obtaining large blooms and plants for the exhibition table, let me offer a few hints, which, by the way, are not intended for those who are at the top of the tree in all that belongs to their cultivation. If I err, then, in my advice, let me ask such persons, through these pages, to correct me. The Chrysanthemum is a very accommodating plant, because it is "everybody's flower," whoever chooses to grow it, whether he possess glass structures or not. Of this we have ample evidence, for in a murky atmosphere they thrive under careful attention; for example, Messrs. Broome and Dale's collections at the Temple Gardens, the very centre of the smokiest city in the world. But of course the blooms of the large varieties need protection from wet and severe weather—that is, if you wish to preserve them. Mr. Broome's plants—that is, those that are not bedded out in the open spots of the ground—are screened from the weather when in bloom by a wide canvas tent, extending a great length; and certainly the sight is a flower show in itself. But any person who has the advantage of a wall or fence can afford them this kind of protection as their flowering season advances; but I should not think of using it, only when the weather required. In the earlier years of competition, many of the best flowers cultivated for the purpose were grown against walls and fences, and received no other protection in frosty weather than a garden mat. Of course, the contrivance was such that it did not injure the flowers. Some also would adopt another mode—that of fixing a small platform, of a few inches in width and length, to the wall, allowing an aperture for the stalk of the flower to pass through. This then would admit of a propagating or any similar glass being used for protecting and assisting in the development of the bloom. But for all ordinary purposes a temporary coping of boards would afford the means of carrying off any excess of rain. The greatest enemy the flower has to contend with as it gradually develops its innumerable petals is damp. I have seen a stand of remarkably fine flowers thrown entirely into the rear of the awards, and that alone by the beauty of the under petals being destroyed through damp. If grown in pots in the houses, fire-heat is occasionally used during wet and cloudy weather, so as to balance the temperature. To those who are not conversant with the practice which is adopted for producing those great and perfect blooms that take the lead at exhibitions, let me inform them that some of the plants are not allowed to produce more than three or four blooms, although their roots may have filled an eleven-inch pot, and their height in many instances may be betwixt five and six feet, and sometimes they will exceed that. Many persons do not grow more than one plant in a pot, removing all laterals as they appear, but never stopping the main stem. Where the object sought is flowers of extraordinary quality, then all flower-buds are pinched off the shoots as they appear, save the centre bud, and this, if perfect, is preferred beyond all the others. The number left generally is in accordance with the strength of the plant. As the buds expand, they require to be carefully examined, to see that no earwigs are secreted; for this insect will in a night commit such destruction as no after-treatment can restore.

The habits or constitutions of the several varieties are well understood and discussed among the regular chrysanthemum growers for competition; in fact, their opinions are canvassed among each other as much as the qualities of a race-horse are elsewhere. Let the young beginner understand also that the petals are not so naturally arranged in their growth as they are produced on the competition stand; for they have previously to undergo the process of what is termed "dressing." As some persons are very clever at this work, they can remove damaged petals so as not to be detected, as sometimes to restore a damaged or deformed flower, when it possesses the other requisite qualities.

Passing from this to the specimen plants for exhibition, we have a word to say in regard to the practice adopted in order that they may obtain plants which shall be admired for their magnitude and abundance of flowers. The rules of most of the societies say that the plants so grown shall be cultivated on single stems, or, in other words, there shall not be more than one plant in a pot. Many of the varieties are of slow growth, yet they are very desirable, and make a grand display, combined with quality of flower and unique habit, when large specimens can be realized,—a glorious example of which was *Little Harry*, as exhibited by Mr. J. George, at the Stoke Newington Exhibition last year. A common observer on that occasion would suppose that the plant was but of one year's growth; for the general treatises on their cultivation that have hitherto appeared do not, as a rule, contradict the supposition. But let me inform my readers to the contrary; for many of those that are choice varieties and of slow growth are at least the stools of the previous year's plants, or perhaps older, unless exhausted by age. They are, after they have done flowering and rested for a short period, cut down and reported into small pots; in fact, treated exactly as you would a specimen pelargonium.

My object in this brief outline has been, as the chrysanthemum season is advancing upon us, to afford the beginner such hints as will aid in maturing his inquiries; at the same time, let those who consider themselves and friends the most competent to impart the required information remember that others who are not exhibitors do not view plants with their eyes shut and ears closed.

JOHN F. McELROY.

HAVING A CALL.—"Sir, you have been to college, I suppose?" said an inspired cobbler to a clergyman.—"Yes sir," was the reply.—"I am thankful," rejoined the former, "that the Lord has opened my mouth to preach without any learning."—"A similar event," replied the latter, "occurred in Baalam's time; but such things are of rare occurrence at the present day."

CONSTRUCTING A VINERY.—No. III.

MAKING THE BORDER.

Having recommended that there should be a concreted bottom for all vine borders, it will perhaps be some assistance to those who are not experienced in the work to give the details of making the concrete. In the first place, it should be understood that fresh lime and some other hard substance, such as coarse gravel, sea-beach, or small broken stones, are the only substances required. Gravel or sea-beach is preferable to stones, and when either of these is used, two barrow-loads of lime to three of the other will suffice, and make an excellent hard bottom; but when stones are used, owing to their coarseness, they require the same quantity of lime to obtain a close and solid bottom as of stone. The lime should be had in quite fresh, and laid in a heap to slake about four hours before it is used. The lime, and whatever kind of stone is used, must be well mixed, and water applied freely as the work of mixing goes on, until the whole acquires the consistency of mortar. It is then in a fit state to be laid down, which must be done immediately. Where a fine material is used with the lime, a thickness of three inches will be sufficient, but with a coarser stone five inches is not too much. From ten to twelve barrow-fuls is enough to mix up at one time, and as soon as this is laid down, give the surface a gentle sprinkle of water, and then beat firm with the back of a spade, and avoid all treading upon it until it is well set, and when no impression of foot-marks is left behind. If the weather is fine with a drying wind, it will get sufficiently firm in about four clear days; but with dull damp weather it will sometimes take a week, or more. Having shown, in the sections of houses before given, the position of the concrete, as well as the drain and drainage, it is only necessary for me to add under this heading, that eight inches of rough stones or brick-heads, with just a sprinkle of finer material on the top of them, will form an excellent drainage for the roots, when placed on the concrete.

Soil for the Vine Border.—An open porous soil, in which the roots can work freely, and air and water find no impediment to their beneficial action, is undoubtedly the best for the vine. A free unctuous loam, containing a good quantity of fibrous matter that has been previously laid by in a heap for at least three or four months, should form the principal staple of the border; to this ought to be added old mortar and broken bricks in the proportion of one cart-load to two of loam, then should follow a liberal quantity of broken bones, the whole being well incorporated before being taken to the border. No animal manure will be required. For my own part, I object to the use of dung in vine borders, when the above ingredients are obtainable, because I am satisfied that it promotes a too vigorous growth, and it is always preferable to have a short-jointed, well matured cane rather than a sappy succulent one, as the former will prove far more productive and satisfactory in the end. Granting that the vine is a gross feeder, and needs an abundance of nourishment, nevertheless, much depends for ultimate success upon the form in which the food it requires is given. If it be of a powerful forcing character, the growth will be correspondingly vigorous, indeed so vigorous, perhaps, that all its energies will be directed to the production of prodigious leaves and branches, and no fruit. But if it be milder, and of a more lasting character, there will be no early excitement, and no falling-off of the supply when the vines in a fruitful state are called upon to perform the part required of them—the production of fruit.

It is no difficult matter to make a border so rich that the vines will be up at the top of the roof, and, if you like, half-way down again, in one season; but borders so made get exhausted before the vines can be said to have arrived at a fruiting condition, and, more than this, they become in a few years a soddened mass of manurial matter, from which all the nourishment has long been exhausted, presenting a barrier against the action of sun and air; consequently the border ultimately gets water-logged, and the soil sour and ungenial for the roots.

Such is not the case when a border is made of the soils above recommended; it will remain for years in a free open state, and will retain for a long period abundance of nourishment for the vines. There will be no early excitement and no sudden falling-off of food for the roots.

Such are my reasons for not advocating the use of manure in making new vine borders, and so satisfied am I of its important bearing on the ultimate success of the vines, that in two new vine borders which I have just completed, altogether about ninety feet long, I have not used any; but I have been careful for the last four months past to collect several cart-loads of brick rubble, besides many loads of the top surface from a pasturage, as well as old mortar which had lain in a heap for years. From these materials I am, so far as human foresight can penetrate, confident of success; and I am sure a

careful examination of these borders, or others made in the same manner, with the same materials, would reveal in a few years' time a perfect network of fine, healthy, active roots, ramifying and extending themselves on every side.

For several years past I have been trying to understand why people will not use more porous materials for vine borders, and the only conclusion I can come to is, that many cultivators like to see them in a close damp soil, in fact, in a soil suitable rather for aquatics than vines, and they seem to think they are in their right element. But surely this is simply for the want of observation. If people would but take the trouble to examine the roots of their vines more often than they do, they would find in borders composed only of loam and dung that after the first few years the roots have made no progress except those just under the surface. All those below this point annually die back, that is to say, they make a fresh effort every year, and push forth a few roots only to be killed on the approach of winter by the action of cold and damp, so that from living roots they soon become nothing but a black mass of decaying matter.

But I must not be hard upon those who have made mistakes in this matter, as many who have advised the reading public have committed the mistake in not giving more precise information. To tell an amateur to use loam for his vine border, and then to leave him to make his own choice, without some specific rules to guide him, is worse than having said nothing at all. The characters of many loamy soils differ so much in their adaptability for the purpose, more especially when not used in conjunction with some opening substance, that they are positively injurious to the roots of vines. Some loams of a tenacious character will get so close and firm, that the roots of vines cannot possibly thrive; and these kinds of loam, when they have lain in one position for years, will sooner or later get water-logged, and become impervious to the action of both sun and air. The natural consequences attending this state of things is a weak growth and the shanking of the fruit; but when no better soil is to be had, the cultivator should add an equal quantity of brick rubble and old mortar, and then the above misfortunes will in great part be avoided. In many parts of the country there is a kind of sandy loam that is more open, and consequently less binding in its character, and eminently suitable for vine borders. The worst of all loams, or rather what inexperienced people would accept for loam in dry weather in summer, is a kind of clay. Such a loam is by exposure to the atmosphere rendered friable and kind to handle all the time it is in a dry state, but immediately it comes in contact with water all the small particles quickly become united into a sort of paste. If a soil of this sort is covered so that the air cannot reach it in a direct manner, it will remain in that pasty condition, and become a serious enemy to the progress of root action.

In connexion with this part of my subject, I have only now to add that a depth of two feet of soil must be given in every case. With a greater width than ten feet, two feet six inches will not be too much next the house. In every case an allowance of at least four inches should be given when the border is made for it to settle down, as recently moved soil of the depth stated will be sure to sink that much. If possible, let the border be made during dry open weather.

J. C. CLARKE.

THE NEW ROSES OF 1867.

Are there no rose-growers who read the Magazine? Is Mr. Prior the only one who has a word to tell us about the new varieties of 1867? Why, we shall soon have the fresh batch from France, and our attentive hopes will be directed to them before we have had any critical information about those that were introduced last autumn.

In default therefore of others who have better opportunities of seeing more specimens of the new varieties than myself, and in hopes that many growers will send their several experiences for insertion in your periodical, mentioning those that they know to be real acquisitions, I venture my own opinions, grounded on what I have seen, and what I have heard on reliable authority, coupled with good rose judgment.

But first of all, Mr. Editor, I have a crow to pick with you, which ought to be a pheasant as it is October. Don't let me hear again of your intention to jilt Madame Vidot to take up with Madame Hosto. I don't mean to question the excellence of the latter, but to cast off the former would be rosarian coquetry. Mr. Radelyffe may write to the papers, and declare that Madame Derreux Douville is worthless; Mr. Flitton may assert that Maréchal Niel and Xavier Olibo are failures; but don't you commit yourself in like manner about Madame Vidot—that's my humble advice.

I have seen but few of the new roses; and, although it is

hardly fair to stamp a rose either as a good or bad one from one or perhaps two blooms, in all probability cut from a small plant, still what have we to judge from except what we do see?

I place *Charles Verdier* first, because not only is it a good rose, but it has novelty of appearance.

Thurin comes next, and seems a general favourite; after the style of *C. Ronillard*.

Horace Vernet is perhaps rather like *Fisher Holmes*, and is not very full in the centre; but English climate and cultivation may make it first-class; for I have seen lovely specimens of it.

Annie Wood is a beauty, much like *Olivier Delhomme* I thought.

François Treyve a capital rose, but the old *Jacqueminot* colour.

Felix Genero was shown a good light globular rose.

Jeanne Marix I also liked; and *Eugène Seribe*, which I have since heard was worthless, certainly showed one good bloom of novel colour.

We can hardly speak of Mr. George Paul's *Duke of Edinburgh*, or Mr. C. Turner's *Miss Ingram*, because they are not yet sent out; but the former is evidently a splendid high-coloured rose, and the latter a pretty addition to our light hybrids.

What can we say of Mr. Robert Ward's lot? We ought to make much of our English seedlings, and they have been very good in many instances; but the raiser of John Hopper stands in such high estimation that his three new seedlings have been so cut to pieces, I guess for the purposes of propagation, that we have had no chance of seeing blooms. On the plant I got of *Mrs. Ward* there was a promising large bud, and good foliage (by the bye, many of the new French roses have unusually good foliage), but, after all, I hear that *Mrs. John Berners* is by some considered the best of the two, which I can hardly credit.

And now I'll name those of which I have seen poor samples, though, as I have said already, it may not be fair to condemn them thus early on such scanty trial.

Two blooms of *Antoine Ducher* were bad indeed. I was told that the rose was really good, and that the specimens exhibited were no indications of the true character of the variety, which I quite hope and believe.

Madame Hoste was as bad at the Crystal Palace as it was good at Birmingham.

Madame Rival thin and washy.

Madame de Falloux insignificant.

Madeline Nonin confused

Bellenden Ker nothing worth.

Sœur Theele and *Comte Litta* both bad, as I saw them.

All the above I have seen, and I have given merely my own opinion, as the report of my own observation.

Next I shall mention what I have heard of other roses not yet alluded to.

Madame Pulliat is recommended to me as of perfect form, and good deep rose colour, though rather small.

Paul Verdier, *Monsieur Woolfield*, *Madame Eleanor Grier*, *Mrs. George Paul*, *Souvenir de M. Boll* and *Madame Margottin* (Tea) are spoken of as promising candidates for favour. *Monsieur Noman* is described to me as very pretty, whilst *Gloire de Montplaisir*, *Triomphe de Soissons*, and *Baronne Haussmann* are condemned as of apparently little or no merit.

Every one, I fear, is disappointed that *Napoleon III.* is not a better rose; the name, the character given of it before it appeared in England, and the lovely plate of it which we all admired, led us to expect more than we have yet seen.

And now may I ask if others will favour us with their experience amongst the new roses, if only they can help rose-growers to secure one additional acquisition, or to avoid a bad rose under a new name?

Although not upon the same subject, still it is closely enough connected with it to allow me to use the present opportunity of mentioning it.

I do not suppose we shall ever induce the French raisers of roses to use more moderate language in describing their new seedlings from year to year; sensational adjectives seem part of their nature. They never will understand that in England we like "deeds, not words." The best auctioneers seldom puff the articles that come under their hammer; but the worst and least successful ones do so be-mouth their wares that they sell for all the less, instead of all the more. But I advocate rather a fuller description; and, as to colour and form, we have surely sufficient samples with which to compare any new roses.

One day this last summer I cut a great many roses of different varieties, and arranged them according to their several shades of colour, from *Prince Camille de Rohan* and

Pierre Notting up to *Niphotos*; and the intervals of colour, so to speak, are few and small, so that instead of being told that all the roses are vivid red, or tender rose, why could not the colour of another well-known rose be named, as that to which the new flower the most nearly approached? The same as regards the description of shape. Thus, for instance, if the French nurserymen will not, I should like our English ones to describe a rose somewhat thus:—

Editor.—Colour of *Xavier Olibo*, shape of *Madame Victor Verdier*; smooth wood, bright large foliage, good strong habit; flowers freely.

We should in such terms see a description which we could understand, and should be better able to know the character and appearance of the rose, when described as after the style of another well known variety, than when shrouded under the indefinite exaggerated verbosity of a French raiser, who is alarmed by the idea that his own beloved seedlings may possibly lack purchasers and notoriety for want of a splendid description.

At any rate, let English growers, when they got them on their soil and prove the foreign roses, give us the benefit of simpler and more faithful descriptions, which are likely, as far as words can, to give us a clear idea of their several and respective appearances. EDWARD N. POCHIN.

SEAKALE.

There has been so much written about seakale, that it is about the last subject I should touch had I not something to say which may be new and useful to many of our readers. In many instances this delicious esculent is regarded as an expensive luxury troublesome to grow, and demanding a great length of time to bring it to perfection. It is time all popular errors in respect of the cultivation of this plant were abolished for ever, for it is one of the easiest and most profitable crops that can be afforded a place in a kitchen garden. During several years past, careful attention has been given it in the experimental ground at Stoke Newington, and every mode of cultivation spoken of in books or thought of in dreams has had fair trial; and we are fully prepared to obliterate from garden literature more than nine-tenths of all that has been written on the subject. We have determined that to grow seakale from seed is absurd, and to be thought of only when there is no other method possible for the cultivator. An emigrant may take seed with him to some wild place, and do right, perhaps, in sowing it; but when once he becomes possessed of roots he ought to think of seed no more. As for English gardeners of all classes, the employment of seed is a deliberate waste of the rental of the ground. It is slow to germinate; it requires much attention in weeding and thinning in its early stages; and it is quite a chance if, at the end of the first season, the roots are large enough to be taken up for forcing. Mr. Clarke has shown how to grow seakale for forcing in one season; but there is another method, one that never fails if carried out with spirit, and which results in the production of roots with crowns twice as thick as the very best that can be grown from seed in one season. Nine-tenths of our readers have guessed at the purport of this paper, and may say already, "Oh, yes, cut up the roots; well, nothing new in that." The guess is both right and wrong. It is true that what we call the "prize" way of growing it (because by this we grew some extraordinary roots that were exhibited on a trade stall at a cattle show, and were the best samples there) consists in propagating from the roots, but it is not true that we follow the old method of procedure; for experiment has taught us that the very part of the root which appears to be the best for the purpose is the very worst, and therefore the majority of those who practise root propagation go the wrong way to work about it.

Seakale roots are now being taken up to force, and we may consider the cultivation to begin from this time. Now, on the subject of forcing there are many errors afloat. We say 50° to 60° degrees is heat enough. Well, so it is. But what will seakale bear, and yet be good? Does any one know the correct answer to that question? I do not hesitate to say that seakale can be forced wherever there is heat, moisture, and darkness, unaccompanied by poisonous or nauseous gases; and it matters very little whether the temperature be 50° or 150°, for the plant will bear the last extreme, and all that is needful on the part of the cultivator is to see that, as fast as it becomes fit for use, the tender elegant shoots are cut, and the roots taken out, and others are put in to succeed them. I force 400 roots annually for my own table, and to give to friends. There is no better seakale ever seen in the district than ours; and there is no better sent to Covent Garden market, or any other market; and it is all grown in the space of seven months, and all forced in a heat of about

100° Fahrenheit. I will suppose that at the present time there is not a root in the place, though I am glad to say, as a matter of fact, that we have plenty. But there is none, say. My first step would be to order a sufficiency of some first-class house, and pay at the rate of 12s. per hundred for it. It would be stacked away in a shed in some dry earth or litter till wanted, and when forcing began a few dozen roots would be packed in cocoa-nut fibre refuse, close beside the two-inch hot-water pipes that connect the lean-to with the Paxtonian, in the long box shown at page 57 of the volume for 1866.* We never shorten in the roots, for that would ruin our scheme. We never bury them, but merely cover them loosely up to the neck with damp fibre close beside the pipes, and leave an empty space above for the fat shoots to rise into. For the shoots to rise through any material is bad practice. Sometimes they acquire a bitter flavour from tan; sometimes the shoots become black at the base, and more or less rotten, through constant contact with damp (and perhaps sometimes cold) material. A space filled with warm air only is by far the best, and this we obtain by putting rough wooden covers over the trough in which the roots are forced. It need not be proved that in this curious contrivance the roots are exposed to a great heat. The small pipes have to feed large pipes when they get beyond the trough, and the object of employing small pipes for the transit from one house to another is to promote a *quick* flow, so that the waste of heat shall be the least possible. Very well; it will be believed that when we mean to make the Paxtonian warm the pipes in trough are at some point above 100° Fahr.; and the seakale is simply quicker in its growth, and, if possible, more tender and delicate when on the table; at all events, we are prepared to back our seakale against any and every sample that can be compared with it, no matter by what process grown.

As the stalks are cut, and the roots are thereby used up, they are taken out, others are inserted in their place, and these used-up roots are taken care of in this way: all their lower roots are covered with some protecting material, such as leaf-mould, cocoa-nut refuse, or whatever else may be most handy; but the thick part of the roots is cared least about, and the packing and keeping is done in such an off-hand way, that it may be said to demand neither time nor space; the fact is, all we do is to take care of the *extreme rootlets*, for out of these we make our plants.

Take a complete root of seakale fresh from the earth, you will find, first, a club-like stem, with a crown one to three inches thick. This stem branches off into fork-like divisions of less thickness, and these again send out long whip-like roots, and from these again proceed the feeding fibres. Now, the *whip-like roots* that do not exceed in thickness a common black-lead pencil, but which average in thickness that of a wheat-straw, are the best parts of the whole roots to propagate from, and make the finest plants possible by *any mode* of propagation. Prepare a good bed, dig it deep, use abundance of manure, make it fat, almost to grossness, with manure, and any time in March take out the roots, cut off the whip-like or pencil-like rootlets; do not rub off or injure more than can be helped the white fibres with which perhaps they will be studded, and cut them all into lengths of two to three inches; nay, if you are hard pressed, and want to plant an acre of ground with the produce of a hundred roots, pencil-like bits an inch long will answer. Before planting, the bed should be dressed up neatly, and raised slightly *above the general level*, except perhaps on some very hungry sand and chalk soils, in which case I should be tempted to sink it *below the general level*. Put down the line, and by means of a bit of hard stick dib the holes fifteen inches apart, and drop the sets in proper end upwards if you can, but it does not much matter, for if wrong way up they grow as well, but are a little later in starting; cover them quite an inch, or even two inches deep, and go away; your work is done for the season. About a month after the planting the little purple leaves will come wrinkling through. Before the weeds have time to get hold of the ground, these leaves will spread, and by the middle of June the bed will be covered with leaves two to three feet long, and all who see the bed will be astonished if told that *that* is the way you do seakale for forcing in one season. The practical reader will think of the necessity of frequent hoeing, and of the too close proximity of the plants. A few bits of groundsel may appear in the early stage of the business, and these the hoe will chop down; but, really, the growth is so fast that there is scarcely a chance to use the hoe, and the thickness of the plants, being only fifteen inches apart, does not at all interfere with the growth of perfect roots, provided the ground is as good as it should be. Land is too dear here to allow of far apart planting of anything that will bear crowding. Let those who can afford the ground put their sets

in two feet apart; here, at all events, we can get fine roots at a foot apart, but the plantation we are now taking up was made at fifteen inches, and the roots are grand.

Very much of course depends on the quality of the soil in such a matter as this. Ours is a deep, fertile, sandy loam lying rather dry, so that in the event of a wet spring the sets are in no danger of rotting. As to the abundant use of manure, if that may seem to upset my argument on the profitableness of this crop, I have to say that when the roots are taken out, the ground is still in good heart for any crop that requires a rich soil free from recent manure. Ridge it up for the winter, and next February plant Ash-leaved kidneys, or sew onions or lettuces on it, and there will be better crops than by the use of fresh manure: the fact is, manure is never lost; if a plant will bear it, as seakale, cauliflower, broccoli, and celery will, my plan is to use plenty—such, indeed, as some of our practical men here consider extravagant. But I reckon on two years' growth from such heavy dressings, and in the second season the ground is in a better condition for many crops than if just dressed with fresh manure. Let me not forget to say, that on the system of growing seakale now advocated, the plant never flowers; so the cultivator has not to go picking out flower stalks, and the plants lose none of their vigour by making seeds. Dig deep, manure heavily, break up the surface well, and plant properly, and you scarcely need look at the bed again, except to admire, and utter exclamations of astonishment, until the time comes, as it has now come, to take up the roots, and thereafter you may have seakale on your table any day you please until the month of March, or even until May, if desirable. We get tired of it always by the beginning of March, and so never take pains to secure a late supply by cool treatment and retarding. In a garden where seakale can be grown, they can also grow something else worth having after March is out. S. H.

THE NEW CONTINENTAL ROSES.

M. EUGENE VERDIER'S LIST OF NEW ROSES FOR 1867-1868.

THOSE LET OUT BY HIMSELF.

TEAS.

Clotilde.—Habit vigorous, having some analogy to "Bougère;" flowers very large, full of colour, changeable, ordinary transparent rose or violet rose, or clouded brick-red.

Laure Fontaine.—Habit vigorous, flowers large, full, well made, creamy white, centre more lively; very free flowering.

HYBRID PERPETUALS.

Aristide Dupuis.—Habit vigorous, flowers large, full, well formed, and of good carriage; superb slate colour, flamed or ribbed fiery; very free flowering.

Aurore du Matin.—Habit very vigorous, flowers very large, of a pretty colour; the reverse of the petals silvery.

Champ de Mars.—Habit vigorous, flowers large, full, in corymbs; lively crimson shaded with violet; very fragrant.

Charles Turner.—Habit vigorous, flowers large, full, very well formed, fine lively red; very bright.

Clotilde Rolland.—Habit vigorous, flowers large, full, having the shape of "Madame Furtado;" fine tender rose cerise; superb.

Comte Raimbaud.—Habit vigorous, flowers large, full, well formed; rose clouded mauve.

Impératrices Charlotte.—Habit vigorous, very perpetual, and full of flowers; flowers large, full, imbricated, in corymbs; tender rose, bright, and very fresh colour.

Madame Rolland.—Habit vigorous, very perpetual, and full of flowers; flowers the form of "Baronne Prevost," of which variety it is a seedling; superb rosy flesh, very distinct, and resembling at a distance "Souvenir de la Malmaison."

Merveille d'Anjou.—Habit very vigorous, flowers very large, very full, opening perfectly; very fragrant and enduring; fine.

Meyerbeer.—Habit vigorous, flowers very large, full, with folded petals; brilliant fiery red purple, clouded.

Reine du Midi.—Habit vigorous, very free flowering, having some analogy to "La Reine;" flowers large, full, well formed; fine soft rose; superb throughout the season.

Sophie de la Villeboisnet.—Habit moderately vigorous; flowers very large, very full, well formed: fine glacé rose; very free flowering.

Souvenir de Caillat.—Habit very vigorous; flowers large, full, in corymbs; violet purple and fiery red; much superior to "Lord Clyde."

Souvenir de François Ponard.—Habit very vigorous, and flowering continual; flowers large, globular, full, well made; petals large, fine lively rose; very fragrant.

Souvenir de Redouté.—Habit vigorous, flowers large, full, well shaped; red purple, shaded with vermilion and scarlet.

Souvenir du Champ de Mars.—Habit vigorous, and flowering abundantly; flowers large, full, well formed; red purple shaded with brown.

Thumbberg.—Habit vigorous, flowers large, full, well made; purple violet; red.

PERPETUAL MOSS.

Madame Charles Salleron.—Moderately vigorous, flowers large, full, glowing red crimson suffused with scarlet, having some analogy from its colour to H. P. "Monte Christo."

SECOND SERIES.

VARIETIES SENT OUT BY OTHER RAISERS.

TEAS.

Jean Pernet.—Habit vigorous, and continuous blooming, and abundant; flowers large, nearly full, fine clear yellow.

Reine de Portugal.—Habit vigorous, flowers large, very full, very well

* Vide article entitled "Heating on the Level," in the issue for Feb. 10, 1866.

formed, and enduring, fine deep golden yellow; very striking, sometimes copper clouded rose.

Souvenir de Maximilien.—Habit very vigorous, flowers large, full, fine red carmine, often marbled with white.

BOURBONS.

Madame Luzet.—Habit very vigorous, flowers large, very full, rose brightly shaded with orange and salmon; very pretty.

Marie Larpin.—Habit vigorous, very free-flowering, flowers medium size, full, very well formed, fine rose, very delicate, reflexed whitish.

HYBRID PERPETUALS.

Abbé Yénière.—Habit moderately vigorous, flowering constantly, flowers medium; full, well-made, superb bright rose.

Alice Dureau.—Habit vigorous, nearly thornless, seedling from "La Reine;" flowers large, full, globular, keeping well; fine fresh bright rose.

Bavillet Deschamps.—Habit vigorous, seedling from "Comte de Bobrinsky" (shades of the heroes of old!), flowers large, full, well shaped, round, fine rose; very brilliant.

Baron Haussmann.—Habit very vigorous, flowers large, full, well-made, poppy red; of grand effect.

Baron Lassus de Saint Genies.—Habit very vigorous, seedling of "Triumpho de l'Exposition," flowers medium, full, lively red crimson. (Has there not already been a rose let out of the above name?)

Baronne de Beauverger.—Habit vigorous, flowers large, full, in corymbs; fine bright rose; very fresh in colour, very sweet.

Baronne de Rothschild.—Habit vigorous, seedling of "Souvenir de la Reine d'Angleterre;" flowers very large, nearly full, well formed, fine rose, deeply shaded; superb.

Christina Nilson.—Habit very vigorous, flowers large, full, globular, well formed, bright rose shaded with poppy colour, edged white; reverse of petals clear satin rose.

Curé de Charentay.—Habit very vigorous, flowers large, full, in corymbs, deep purple; very fine.

Deuilde l'Empereur du Mexique.—Habit very vigorous, very free flowering, flowers large, full, well formed; blackish purple clouded and shaded with fiery red.

Docteur Hurta.—Habit very vigorous, seedling from "Baronne Prevost;" flowers very large, full, flattish, lively rose shading off to purple.

Duchesse d'Aoste.—Habit vigorous, flowers large, full, flat; fine bright glossy rose.

Elie Morel.—Habit very vigorous, very perpetual; flowers very large, very full, lilac rose, white at the edges; very fine.

Enfant d'Ameugny.—Habit very vigorous, flowers large, full, well formed; delicate rose striped white.

Ernest Boncenne.—Habit vigorous, seedling from "Madame Laffay;" flowers medium, full, globular; brilliant rose in the centre, the exterior rose marbled with carmine red.

Général Barral.—Habit very vigorous, flowers moderate, full, well shaped; fine violet rose.

Général Dessaix.—Habit very vigorous, flowers very large, very full; glowing fiery red shaded with poppy.

Jean Brosse.—Habit very vigorous, flowers medium, full, cupped; deep rose.

Jules Bourgeois.—Habit vigorous, flowers medium, full, well formed, deep velvety red.

La France.—Habit very vigorous, flowers very large, well-made, and enduring, scent exactly that of the cabbage rose; the petals are large; silvery in the centre, fine striking violet rose at the exterior.

La Sirène.—Habit vigorous, flowers large, full, red amaranth purple passing to rose-purple.

Lisette de Beranger.—Habit vigorous, flowers moderate, full, well shaped, globular; fine fresh rosy flesh, resembling the colour of "Bourbon Queen," and passing afterwards to full white bordered rose.

Louis Bulliat.—Habit vigorous, nearly thornless; large, full, keeping well, rich colour; red crimson clouded velvety black.

Madame Adèle Huzard.—Habit vigorous, flowers medium, full, globular; lively rose bordered whitish.

Madame Barriot.—Habit very vigorous, flowers very large, full, clouded carmine rose; very fine.

Madame Chirard.—Habit very vigorous, seedling of "Souvenir de la Reine d'Angleterre," flowers very large, very well formed, full, fine live y rose.

Madame Gonod.—Habit very vigorous flowers medium, fine clear satin rose, reverse of petals nearly white.

Madame Grendier.—Habit very vigorous, flowers large, full, fine salmon rose.

Marie Girodde.—Habit very vigorous, seedling of "Triomphe de l'Exposition," flowers large, full, well imbricated; fine fresh rose; magnificent variety.

Madame Noman.—Habit vigorous, flowers medium, full, well shaped, pure white.

Pitford.—Habit vigorous, flowers large, full, well shaped; fiery red, centre pansy velvet; very fine.

Président Villermoz.—Habit very vigorous, flowers very large, full, well-formed, clear clouded rose; superb.

Prince Humbert.—Habit very vigorous, flowers very large, full, well shaped, velvety, violet red; very bright.

Princesse Henri des Pays-Bas.—Habit moderately vigorous, from "Madame Recamier," flowers medium, full, silvery white shaded flesh.

Souvenir d'Adrien Bahivét.—Habit vigorous, flowers large, full, globular; velvety reddish crimson, clouded purple and violet carmine.

Souvenir de Madame Corval.—Habit very vigorous, flowers medium, full, very well formed, fine yellowish rose.

Souvenir de Ponsard.—Habit very vigorous, flowers large, full; fine metallic rose brightened with fiery red.

Tournefort.—Habit very vigorous, flowers very large, fine poppy red.

Vicomtesse de Vesins.—Habit vigorous, seedling from "Triomphe de l'Exposition;" flowers very large, very full, like a rosette in centre; fine fresh bright rose; superb.

HYBRID PERPETUAL NOISETTES.

Boule de Nieve.—Habit vigorous, flowers medium, full, well formed, pure white.

Coquette des Alpes.—Habit vigorous, flowers medium, well shaped, centre white shaded carmine.

PERPETUAL MOSS.

Souvenir de Pierre Vibert.—Habit very vigorous, flowers very large, full; very deep red shaded carmine and bishop's purple; very free flowering, and blooming freely and continuously; superb.

W. D. PRIOR.

NEW GLADIOLI, HYBRIDS OF GANDAVENSIS, FOR 1867-68.

The following is M. E. VERDIER'S List, just issued.

Bavillet Deschamps (Paulin).—Flower very large, very open, fine scarlet red, very large carmine spots upon deep white.

Bernard de Jussieu (Souchet).—Flower large, very open, well formed, deep clouded violet tinted cerise and purple, blotches purple upon dense white; colour new, indescribable, and of remarkable beauty.

Etendard (Souchet).—Flower very large, very open, well formed, white lightly flamed (or flaked) with lilac or bluish violet, spike very long, measuring about 36 inches.

Eugénie Scribe (Souchet).—Flower very large, very open, well formed, very soft rose, flaked red carmine.

La Fiancée (Souchet).—Flower large, well formed, very pure white, little spots of violet blue; very pretty.

Marie Verdier (Paulin).—Flower very large, very open, deep salmon rose, very large white blotches, traversed with a line of violet.

Mozart (Souchet).—Flower very large, very open, spike very full, bright rose lightly tinted with violet, very freely flaked with deep carmine, very large spots, pure white; magnificent variety.

Norma (Souchet).—Flower medium, spike very full, pure white, very rarely and very lightly flaked with delicate lilac.

Princesse Alice (Souchet).—Flower very large, very open, well formed, delicate lilac lightly tinted with rose, very large white blotches clouded; charming and novel, variety dwarf, and altogether of first-rate merit.

Rossini (Souchet).—Flower large, well made, very long spike, deep purple red, lined and spotted white.

Scmiramis (Souchet).—Flowers very large, very open, well made, spike very long, carmine rose to deep white, extensively flaked with bright carmine; a brilliant and splendid variety, without a rival.

Ulysse (Souchet).—Flower large, well made, very fine glossy rose, very fine colour.

Uranie (Souchet).—Flower large, very open, pure white, freely flaked with lively carmine rose; very fine and brilliant variety.

Alexandre (Souchet, as are all the following, this series being of less merit or less novelty than the preceding).—Flower large, well formed, very fine lively red.

Citrus.—Flower medium, upper divisions clear yellow, lower divisions very deep yellow.

Henriette.—Flower large, well made, tinted and flaked lilac; a dwarf and charming variety.

Isabelle.—Flower medium, very fine spike, pure white, large blotches of very deep carmine.

La Favorite.—Flower large, rose flaked carmine, lower petals clear yellow.

Leonora.—Flower large, well made, red cerise, lightly tinted orange.

Mébul.—Flower very large, well formed, spike often in whorls, clear currant red, lined and flamed with white.

Molière.—Flower very large, very open, well made, cherry red; very large spots of pure white.

Oscar.—Flower large, well made, very brilliant, bright cerise, white spots.

Stella.—Flower large, well made, dense white, lightly tinted yellow and rose, flaked carmine red.

Thalie.—Flower large, well made, white flaked lilac, striped carmine; fine vigorous variety.

Thunberg.—Flower very large, well made, very clear orange cerise, very large pure white spots.

GREEN LIZARDS.

These interesting little pets are quite ready to banquet on a variety of delicacies, such as meal-worms, caterpillars, planet-bees, butterflies, small pieces of meat, and some kinds of fruit. Water sweetened with a little sugar they do not object to, but sup daintily of. A well ventilated glass house or case will be found a convenient residence for them, and a small flower pot with a notch broken in its edge, inverted, and covered with rock-work and ferns (which may be planted in the interstices), forms a snug retreat into which the lizards can retire when seeking to avoid the wear and tear of too much society. It will be found a good plan to establish a meal-worm preserve, from which to draw from time to time game for the saurian epicures. This will be found especially valuable as cold weather comes on, and outdoor insects grow scarce; and thus the affair is arranged. Take a medium-sized earthenware preserve jar, half fill it with bran, bury a number of mutton chop or other bones of convenient size in it; then place a goodly number of meal-worms, the larvæ of *Tenebrio molitor* or *T. obscura*. In due time, as changes in insect life go on, other meal-worms will appear on the scene, and like rabbits in a warren, will be at hand when wanted. Place a perforated cover on your jar, and put it in a dry place. It is somewhat curious that these bronze-green little creatures should at times show such determined animosity towards each other. Some short time since a friend of ours kept a male and female lizard in the same case, formed a nice little matrimonial establishment for them, and confidently looked forward to their future as certain to be one of uninterrupted domestic bliss. But, alas for the mutability of affairs, saurian as well as human! the demon of discord established himself in their bijou residence. Flinks and tosses were rapidly succeeded by sulks and snaps, until matters were brought to a culminating point by Mrs. Lizard's nipping a piece of her husband's tail off; and although it was the end of the caudal extremity, it was by no means the end of the quarrel, for, as the periods of connubial storm and estrangement grew gradually longer, Mr. L.'s tail became most alarmingly shorter, until it scarcely deserved the name of a tail at all. Then our friend, thinking matters had gone quite far enough, stepped in, sternly resolved to do his duty; so he at once became a sort of Cresswell Cresswell of private life, and ordered a separate residence and maintenance, when all that remained of Mr. L. soon recovered its wonted briskness and activity.—SALAMANDER, in *The Field*.

A LADY asked her gardener why the weeds always outgrew and covered up the flowers. "Madam," answered he, "the soil is mother of the weeds, but only step-mother of the flowers."

Calendar.

WORK FOR WEEK COMMENCING OCTOBER 26.

Kitchen Garden and Frame Ground.

KITCHEN-GARDEN crops to be kept clean, all dead leaves removed, the ground frequently hoed between cabbage, &c. Thin winter spinach, clear off Brussels sprouts in compartments as used, and dig the ground over as soon as vacant.

LETTUCES.—Treat as recommended for cauliflower.

CAULIFLOWERS potted for keeping over winter should be kept rather dry, and as much as possible exposed to the weather, to keep them stocky and hard. Keep the lights or glasses on always at night from this time forth, removing them every morning, except during frost or drenching rains. In wet muggy weather, tilt the lights upon blocks of wood or bricks, so as to create a circulation of air amongst the plants, and yet keep them from being soddened with water.

DRAINAGE.—About three-fourths of the complaints that reach us of the misbehaviour of fruit-trees, and the failure of vegetable crops, and the unsatisfactory blooming of roses and many other things, have one common origin—the want of drainage. We see people labouring away at the surface, raising the level by additions of soil, manuring liberally, removing plants that have not prospered, and planting others in hope of better luck; and we can tell them, when all is done, that until they secure the first essential of success—a rapid removal of surplus water—there can be no success to their efforts, manure and plant as they may. At this time of year you have but to open a hole one spade deep, and in less than ten minutes that hole will be filled with water, which proves that the whole surface soil is saturated, and that any cavity, tunnel, or opening would immediately draw off the surplus water, according to the capacity of the opening, and that therefore very simple and inexpensive means would suffice to enable the soil to get rid of the water which is in excess of its power of absorption. A two or three inch pipe laid at a regular fall, at about three feet beneath the surface, will effectually drain a breadth of from 20 to 100 feet in width, according to the nature of the soil, and its relative level. Generally speaking, the drains should be three feet deep and twenty-four feet apart; but in a wet clay they will not be too close at twelve feet apart. In districts where there is any apprehension of the disturbance of the drains by moles, one-inch pipe should be used. On very flat land a fall of one in fifty will suffice to keep the water moving; but a rapid fall is preferable if the outlet is low enough to admit of it, as in times of sudden heavy rainfall a quick removal is very desirable. Of course we cannot here enter into the details of the subject; but, as this is as good a time as any to drain land that requires it, we again remind our readers that good drainage promotes the warmth and fertility of the soil; and, on the other hand, a water-logged soil is almost poisonous to every kind of plants that come under the care of gardeners.

Flower Garden.

AURICULAS must be kept clean and dry; any drip from the frames will do incalculable mischief; at no time, not even during frost, should the roots be dust-dry; it causes an exhaustion of the plant which will tell seriously on the bloom hereafter.

CARNATIONS will often be found beset with green-fly during damp warm weather at this time of year; in which case fumigate at once, and again a few days afterwards, and they will probably remain quite clean till they begin to grow again in spring.

CULTIVATION OF SHOW TULIPS.—Let us say very little here about the value of tulips. There are some now catalogued as high as twenty guineas each, but beginners need not be afraid of prices, because the good old cheap kinds, the names of which are celebrated in the annals of tulip culture, are beautiful and indispensable even in the most costly collection. Those who will pay twenty guineas each for tulips this season must have such cheap sorts as Polypemus, Strong's King, Rose Baechus, Gloria Mundi, Brilliant, &c., &c.; and bulbs for a bed of sixty rows can be obtained of such growers as Mr. Lawrence, of Hampton, and Mr. Turner, of Slough, for from fifteen to twenty pounds. As there are seven bulbs in a row, this is at the rate of ninepence or tenpence each all round. This statement may be information to many readers, who suppose a fortune to be required for the purchase of a bed of tulips. Of course, at such a price rare kinds cannot be had, and many first-class sorts average five shillings to twenty-one shillings each; nevertheless the named kinds are all good, and when obtained at such a cheap rate will make a splendid display; and when the cultivator has become used to them, other varieties of more costly quality can be added as desired. A few pounds spent every year in improving the collection will bring a good return in the interest that will be created in watching for the flowers of the latest acquisitions, and in admiring them when they are out. There need be no quackery in the growing of the tulip. It is quite hardy, and well able to take care of itself, if provided with reasonable accommodation. There are a few points, however, of great importance. The bed should be in an open sunny spot, with some kind of shelter from north-east winds; and there is no better shelter than a mass of trees and shrubs, far enough off to cast no shadow on the bed, yet near enough to break the force of the blast and warm the air that passes through. A belt of shrubs twenty feet wide will raise the temperature on the lee-side of them four or five degrees on a keen windy day in March, solely by checking the movement of the wind. In a coppice it will be found to be quite mild and pleasant on a day when in open meadows the wind cuts like a knife, and the frost is unbearably severe. Shade will not do for tulips; the drip of trees will not do; fresh air and sunshine are indispensable. But there is a matter of still more importance, and that is drainage. If the position is naturally well drained, he content; but if not, make use of pipes to carry the water away. Do not trust to a substratum of brick-hats, as some foolish people do; brick-bats below a bed do not carry the water away; they simply hold it for the injury of whatever the bed contains. The soil best suited to the tulip is a free, fertile, sandy loam. If there is no suitable soil in the place, procure, if possible, the top spit of a good pasture. This ought to lay in a heap for three years, and it is then first-rate for tulips. You will see near field gates in most parts of the country great heaps of grass turf, twich, and other gatherings from the field. Generally speaking, when these heaps are well-decayed, they are unequalled for a tulip bed. If the loam contains plenty of decayed fibre, animal manure is not wanted; but if it is poor, a fifth part of very old hotbed manure may be mixed with it with perfect safety, but it must be thoroughly decayed, or it will do mischief. In making the bed, if the soil on the spot is suitable, dig it two feet deep, and

break it up well. If it is not suitable, take out the soil two feet deep, and fill in with the selected soil. The bed must be four feet wide, and of any length you please. It is a good plan to make a short bed, and lengthen it from year to year as the stock increases. This is better than aiming at too much in the first instance. If you should be persuaded to soak the bed with strong manure-water before planting, you may expect bad flowers. In some parts of the country a fallacy in favour of this process prevails, and is very injurious. The tulip does not require stimulants. The best way to keep up the bed is to enclose it with boards placed on edge; these boards should be one inch thick and four and a half inches wide; they are to be fixed half an inch deep in the ground, so as to stand four inches above the level, and the bed is to be made up to the level of the boards, within an inch or so; in other words, the bed is to be raised above the level and enclosed in a sort of box. Before planting let the bed be forked over again, and raked to a nice convex outline.

The first thing preparatory to planting is to mark the edge of the board both sides of the bed at intervals of six inches. At each mark there will be a line of bulbs six inches apart, consisting of seven bulbs. The rows are counted lengthwise. The flowers next the edge are the first row; those next towards the centre, the second row; the next the third row; and the centre flowers form the fourth row; thus:—

It will be understood that the fourth row should comprise the tallest flowers, the third the next tallest, and so on, to the edge. On referring to a tulip catalogue it will be seen that figures are attached to the names; those figures are to indicate which row the variety should be placed in, but the rule need not be followed strictly, for second-row flowers may often be put in first or third row, third-row flowers in second row, and so on. As a rule, however, the figures are a guide to the heights, but a strong bulb of a first-row kind will generally grow taller than a weak second-row, and so on.

It is necessary now to say that tulips are divided into three classes, namely, *Roses*, which have a white ground and crimson, pink, or scarlet marks; *Byblæmens*, which have white grounds and purple, lilac, or black marks; *Bizarres*, which have yellow grounds and marks of any colour. There are various ways of arranging them, but the best is to place them alternately from the first to the fourth row, and then to reverse the order to the other side, so that one side of the bed is a counterpart of the other. This may be illustrated by a table, thus:—

Rose	Byh.	Biz.	Rose	Biz.	Byh.	Rose
Byh.	Biz.	Rose	Byb.	Rose	Biz.	Byb.
Biz.	Rose	Byh.	Biz.	Byh.	Rose	Biz.

The process of planting may be explained in a word. Prepare a straight lath long enough to reach across the bed. Mark it accurately at intervals of six inches. Lay it down from a mark on the board to the corresponding mark on the board opposite. With a piece of stick of suitable size make a hole at each mark on the lath, throw in some silver-sand, and then insert the bulb with the crown four inches below the level of the bed, and fill up with silver-sand. Many growers reject the sand because in their districts it is expensive. But then in very wet winters they have losses which probably amount to quite the value of the sand, so upon the whole they are not gainers. Every loss makes a gap in the bed which is unsightly, and the sand is a great protection. An old tulip bed is like potting compost, owing to the annual introduction of silver-sand in the process of planting.

The following is a list of cheap first-class sorts, which every beginner should possess, as they stand in the foremost rank at all our great exhibitions. It must not be supposed, however, that those named below can be had at an average of ninepence each; they will range from half-a-crown to five shillings each, or thereabouts.

A SELECTION OF 175 VARIETIES OF SHOW TULIPS.

BIZARRES.

First Row.—Alhion, Dr. Horner, Goldham's Fortunius, Golden Fleecce, King of Tulips, Marshal Soult, Osiris, Roi de Navarre, Groom's Ruhini, Sir Edward Codrington, Lawrence's Solon, Lawrence's Selim, Stein's Napier, Tolémachus, Clark's Ulysses.

Second Row.—Ariadne, Apollo, Bizard Le Kaine, Coronation, Charbonnier Noir, Captain White, Darius, Lawrence's Glencoe, Gloria Mundi, Lawrence's Ostade, Optimus, Lyde's Oddity, Pilot, Lawrence's Peacock, Strong's Titian, William IV.

Third Row.—Carter's Leopold, Charles X., Captain Sleigh, Delaforce's King, Lawrence's Fahius, Lord Strathmore, Lord John Russell, Magnum Bonum, Milton, Ophir, Polypemus (feathered), Polypemus (flamed), Prince of the Netherlands, Strong's Hero, Salamander, Walker's King.

Fourth Row.—Dickson's Duke of Devonshire, Lawrence's Donzelli, Emperor of Austria, Lord Collingwood, Proteus, Sharp's Victory (alias Sultan), Lawrence's Sbeet Anchor, Warsaw.

BYBLÆMENS.

First Row.—Bienfait, Chellastou Beauty, Enclid, Gloria Alborum, La Belle Narine, Parmigiana, Goldham's Prince, Queen of the North.

Second Row.—Lawrence's Friend (alias Addison), Brown's Wallace, Bijou des Amateurs, Blomart, Cleopatra, Countess of Harrington, Lawrence's Diogenes, Euterpe, Gibbons's Enchantress, Grand Monarque, Ilandois, Ivanhoe, Joseph Strutt, Lalla Rookh, Lewald, La Virginité, Lawrence's Lord Stanley, La Jolie, La Latier, Malibras, Maid of Orleans, Mentor, Gibbons's Purple Perfection, Penelope, Prince Charles, Reid's Prince Albert, Willmer's Queen Victoria, Queen Charlotte, Rubens, Smith's Wellington, Super et Noir, Victoria Regina, Violet Blondeau, Violet Rougatre, Winifred, Zoe.

Third Row.—Acapulca (alias Roi de Siam), Gibbons's Britannia, Black Baguet, Cineinnatus, Colossus, Desdemona, Duc de Bordeaux, Duc de Boufflers, Gibbons's Elegans, Franciscus Primus, Grotius, General Barneveldt, Grand Sultan, Holmes's King, Lawrence's Lady Errol, Lawrence's Lord Hawkesbury, Michael Angelo, Miss Porter, Princess Charlotte's Cenotaph, Princess Royal, Lawrence's Patty, Lawrence's Priam, Tintorette.

Fourth Row.—Ambassador, Alexander Magnus, Lawrence's Camarine, Captain Lampson, Commodus, Lawrence's Elthron, Louis XVI., Saint Paul, Thalia, Violet Quarto.

ROSES.

First Row.—Searnell's Bijou, Cerise Blanche, Catalina, Fleur des Dames, Kate Connor, Madge Wildfire, Rose Juliana.

Second Row.—Aspsia, Andromeda, Cerise à Bella Forme, Comet, Lawrence's Cynha, Duchess of Newcastle, Groom's Duchess of Sutherland, Dutch

Poneau, Slater's Fairy Queen, Goldham's Maria, Lawrence's Lady Waldegrave, Clark's Lavinia, Mary Lamb, Mason's Matilda, Perle Brilliant, Perle d'Orient, Rose Imogene, Triomphe Royale.

Third Row.—Lawrence's Aglaina, Anastasia, Claudiana, Lawrence's Duchess of Clarence, Fanny Cerito, Lord Byron, Rose Canuse, Rose Brilliant, Rose Galatea, Lawrence's Mary Anne, Rose Cordelia, Rose Walworth, Thalestria.

Fourth Row.—Lawrence's Clarissima, Comte de Vergennes, Lawrence's Emily, Madame Vestris, Mountain Sylph, Midland Beauty, Prince William, IV., Rosa Blanca.

Fruit Garden and Orchard House.

CURRENTS AND GOOSEBERRIES should now be lifted if required, as the next year's crop will be less jeopardised by getting them early to the places in which they are to fruit. Fork in a good dressing of manure between the trees in old plantations. Put in cuttings of choicest sorts; the cuttings to be straight ripe shoots of this year, and all the lower buds removed, so as to prevent the throwing up of suckers.

FRUIT-TREES to be planted as soon as possible; manure not to be used unless the ground is in a poor condition, and then a little fresh soil should be used with it if possible. Turf from the roadside, clay, clearings of ponds and ditches are excellent materials to invigorate an old worn-out soil required for fruit culture, as also to give body to poor sandy and chalky soils. In planting, keep all roots near the surface; never plant any tree deeper than it was planted before, and if it was evidently too deeply planted before, give it a better chance than it had previously by more shallow planting. Stake as soon as planted, to prevent rocking by the wind, and at the same time prune.

Greenhouse and Conservatory.

GREENHOUSE.—On bright days open all the ventilators, to cause a free circulation of air amongst the plants. Avoid using fire-heat as much as possible consistent with the safety of the plants, and give very little water to those that have finished their growth, or which it is desirable to throw into a state of rest. Plants in pits will endure short periods of frost better if kept well aired and moderately dry. In case of a severe frost, now to be looked for, light a brisk fire early in the day; give air while the sun shines, shut up early, and trust to covering up rather than keep the fire burning all night. A clear sky and a few points of north in the wind may be considered indications of frost, and at such times the cultivator should be on his guard. Generally we have one sharp frost at this season, and then no more till near or after Christmas, and the frost generally follows close upon heavy rains.

PRIMULAS AND CYCLAMENS to be kept in the warmest part of the house, and have every encouragement to push forward to bloom. Keep these near the glass where there is no drip.

PLANTS IN FRAMES will soon be infested with mildew now, if kept close or damp. Though nothing should go dust-dry, it will be best always to defer watering till the weather is clear and bright, and then water well the first thing in the morning, that the pots and plunge material may be somewhat dry before night; one good watering will go a long distance now. During keen north-east winds—not very prevalent at this season—soft-wooded plants suffer severely if kept very dry, and at the same time they will not then bear so much exposure as at other times. Keep the plants clean by removing dead leaves and cutting off the soft tops of any green shoots of geraniums, &c., which show signs of mildew.

Stove and Orchid House.

STOVE.—There are comparatively few plants in bloom now, and those few must be made the most of. Many subjects, however, require to be started into growth, and the necessary repotting and pruning must be attended to. A few good orchids are in bloom now, such as *Odontoglossum grande*, *Phajus grandiflorus*, *Dendrobium Paxtoni*, *Cypripedium purpuratum*, and these must have sufficient heat and moisture. Orchids approaching a dormant state should be kept comparatively cool and dry, but due caution must be exercised to avoid all extremes. This is a good time for a general repotting of stove plants that flower in the summer, as it affords them a long growing season, and they can be carried through a succession of shifts for the production of well-furnished specimens. The usual routine of treatment is in the majority of cases the best. The plants are cut down, and as soon as they break fairly are shaken out, the roots are cut back, and they are potted in small pots, and have a little extra heat to promote the formation of new roots. Then as they fill their pots with roots they are shifted on till they occupy the pots they are to be bloomed in. Solar light is now becoming a scarce commodity, and the careful cultivator will catch all he can. Clean glass, climbers a little reduced, and plants most in need of light put as high up as possible, are three direct ways of obtaining the fullest benefit of the present subdued daylight.

Forcing Pit.

PEACHES in the forcing-house to be pruned at once; the roots top-dressed, the branches washed, and the lights put on. But give plenty of air. Vacancies may now be filled up in the peach-house, and nothing better for the purpose than bearing trees. In many gardens a reformation is taking place in the cultivation of peaches. Healthy trees producing but small crops on open walls are being removed and planted in Paxtonian houses, which by their steep pitch and abundant ventilation are admirably adapted for fruit culture. Generally where peaches are unproductive on open walls the climate is most to blame, and the mere protection of glass, even without fire-heat, suffices to convert barren into fruitful trees, besides the fact, which must always be borne in mind, that trees under glass invariably get more attention than those in the open air. Rivers's Early Victoria is the earliest peach known, a week earlier than Early York. The same raiser's Early Albert is a good peach for forcing, but of less value than the former. Other good varieties to force are Mignonne Grosse, Galande, Early York, and Red Nutmeg. In planting peaches on open borders, let attention be first given to drainage; if the soil is light, lay down six inches of tenacious loam or clay, or turf from a loamy pasture, and about three inches of rotten dung, and then stir the whole, and mix this material with the staple to a depth of two feet, mixing the ingredients well together. The peach, nectarine, and apricot, all require a firm, substantial, and somewhat adhesive soil, a south aspect, and a dry bottom.

STRAWBERRIES.—As the stock of potted strawberries intended for forcing will now require special attention, we bring before our readers an admirable method first adopted by Mr. Sparkes, of St. Mary's Cray. He says: The following method may be adopted by any who are preparing to force strawberries next spring, if their plants are now in pots with well ripened crowns. By this method finer forced fruit can be produced than

by any other. I lay runners in the usual way, in 60-size pots, about the latter end of June; and here I will just state, that they should be layered, if possible, from one-year-old plants that are very strong and healthy, as they will produce the best runners. I keep them well watered, repot the last week in July, or first week in August, in thirty-two's, or six-inch pots. Soil, turfy loam two parts, road-sand two parts, cow-dung one part, with a sprinkling of soot; well drain the pots, and when potted off place them in a good open situation, fully exposed to the sun. I give them plenty of water, never allowing them to flag by any means. By October you will have strong plants, with large solid crowns, and the pots full of roots. Now they must be watered very sparingly, and kept almost dry, that they may ripen their crowns well, and go to rest. I pack them in ridges, and well protect them in frosty weather. For early purposes, I plunge them in a pit, with bottom-heat, about 65° or 70°, and as soon as they show their buds I plant them out in the troughs. The troughs are made of rough deal, from six to twelve feet in length (or any length that may be most convenient), eight inches in depth, seven inches wide on the top, five in the bottom, with holes in the bottom for the water to pass off. Over these holes I put large sherds, with their convex sides downwards, then small ones all over the bottom of the troughs. On these a layer of fibre, turfy loam, broken in pieces about the size of small hen's eggs; turn the plants out, remove all the drainage I can without injury to the roots. Plant them in the troughs, with a space of two inches between the ball of each plant. I fill up with three parts turfy loam and one of road-sand, that has been well incorporated together, working in very solid around the plants with a short stick, or rammer, the crowns of the plants being just level with the top of the trough; place them on the back shelves of the vinery, or in the strawberry-house; give them a good watering with tepid water, and you will see the advantage of the trough over the pot. They will send their roots down in the troughs, and all around the sides, developing their beautiful glossy leaves, and sending up their immense trusses of bloom. I give plenty of air when they are in bloom, and they will set well; they will only require watering once a week in the troughs during the months of December, January, and February; and twice a week in March, April, and May, will be quite sufficient, which, I think, is a very great advantage over pot culture. Amongst extensive growers, and where labour is an important item in the spring, when there is so much to be done in every department, one thousand, or fifteen hundred, pots to be watered every day, and twice a day when very hot, will and does take up a very great amount of time and labour. For a late crop in troughs, the following plan may be adopted, and will produce a good crop, without the use of pots. Take off young plants, or runners, the first week in July. Make choice of those that have roots from half an inch to one inch in length. Prepare a bed, in a good open situation, five feet wide, and any height that may be required. Make the surface of the bed when marked off, very solid, and put on a layer of good rotten stable manure, and cover with three inches of soil from the sides or alleys. Make the bed level, and plant one foot apart. Press the soil firmly around, and keep them well watered. They will soon make new roots, and by the autumn will be strong plants. Take them up in March very carefully, and plant in the trough. The sorts that I cultivate are Keen's Seedling for early, and British Queen for a late crop. The troughs may be made ornamental, and placed on the sideboard when the fruit is ripe, and no one will be in doubt, I think, as to their appearance. I can only say, I have grown strawberries for dessert, for the market, and the exhibition table, and have been a successful exhibitor, and I have grown them in different ways; but I have never carried such a crop, and grown them to the perfection as I have in the troughs, during the commencement of the present year.

Correspondence.

USES OF SAWDUST.—I have got several good hints from your Magazine. One which I will refer to now is the use of sawdust, about which you had some articles a few weeks back. I would premise that I cultivate about an acre and a half of land by way of amusement. I can give it none of my own work, only a little superintendence. I have to find labour and rent, and I am able to say that my balance-sheet shows a very good margin in my favour. I cultivate it with the intention of supplying my own table with the best of vegetables, selling wholesale a few of the earliest crops, and using all the rest in the keeping of pigs. I generally keep from 15 to 20 pigs, and perhaps 40 or 50 fowls, so that I have an abundance of good manure. Now, then, with regard to the sawdust. My greatest trouble had been to find litter for my animals. Straw could only be obtained at 60s. or 65s. per ton, and frequently could be hardly got for that; so that I found this article added very much to my expense. But when I read your sawdust article, it struck me that that was just the thing for me. I found I could get a sack of sawdust for 6d., and I immediately procured a supply. I found the pigs were delighted with their bedding; their coats, from the friction of the sawdust, put on a most healthy appearance, and the terebinthine odour of the sawdust gives a most wholesome smell to their houses. But it is in regard to another application of sawdust that I now write. You have had several papers lately on the storage of root-crops. I had about ten sacks of potatoes which I wished to take great care of: they are a very good sample of flukes. I have an out-house at the back of my house, the bottom of which is used as a coal-house. All round the top is a shelf, something like that shown in your sketches in your number for October 12. I first covered the shelf about six inches thick with sawdust, then put on the potatoes, and then covered them with a layer of sawdust about six inches thick. I fully expect they will come out next April and May in prime condition. I would say that many of my flukes were 1lb. in weight, and two of the heaviest weighed 2lb. 7 oz. I have a quantity of mangold, which I intend storing on sawdust in a similar manner, and lightly thatching with straw. Allow me to give another hint in the gardening way. I have a friend who lives in the neighbourhood of London. He has a house about twenty feet wide, and a garden behind same width, running back about eighty feet. Now, such a piece of ground ought to keep his family, which is small, in garden luxuries, but he gets nothing: his potatoes are small and soapy, his cabbages are eaten out with slugs, his peas are all consumed by the sparrows, and his cabbages, even the black, are also appropriated in the bud by birds. He complains of the dearth of labour and the expense of manure. My advice to him is to burn all the bones of the house in the kitchen fire, and not many at a time, and throw all the ashes of the house over the garden. This is a plan I have long followed; by this means the whole of the phosphates of the bones are utilized, and the small amount of potash salts in the

ashes given to the ground, while the texture of the ground is much improved by the open nature of the ashes. If my friend would go to the trouble to get an ash-pit in the garden, and get his servant to empty the slops of the house therein over the ashes, an abundance of manure would be obtained, which, with the bones and deep digging, would go far to remedy all his difficulties.

AN ENEMY TO WASTE.

THE NAPOLEON WILLOW AT KEW.—In your paper of the 12th instant, under the heading of "A 'Napoleon's Willow' at Kew has been cut down," it is stated that the last stumps of the willow trees that overshadowed Napoleon's tomb were removed in 1840. This must be a mistake, as in the year 1858, when I visited St. Helena and Napoleon's tomb, there were willow trees overhanging the tomb of very large size and growth, certainly of much greater age than eighteen years could produce, supposing that the original trees were removed in 1840, and others planted in their place. Those trees were shown to me as originals, and must then (in 1858) have been at least forty years old, allowing even for the very rapid growth of willows in a tropical climate, the trunks being of large girth; and, further, there being no care taken at that time of either Longwood or the tomb, the trees were almost pulled to pieces by travellers of all nations taking cuttings and pieces of the bark as souvenirs. I took a cutting on the occasion, but it unfortunately died; however, on again visiting the island in 1865, I found the willows strictly guarded, under the direction of an old French officer, sent out in charge of Longwood and the tomb, both of which have been presented to the French by our Government. The cuttings being now difficult to obtain, I got one through the courtesy of a friend of mine, a French naval officer, and prizing it more in consequence of the difficulty in obtaining it, I have now got a very promising young tree. There may have been some willows removed from near the tomb in 1840; but I think it is due to my tree to show that it is descended directly from one of the original trees that used to overshadow the tomb before the removal of Napoleon's remains to France.

SALIX.

EXPERIMENTS WITH VARIEGATED ZONAL GERANIUMS.—Having been engaged making a few experiments similar to those of Doctor Denny, and taking a great interest in his experiments, as detailed in your Magazine, I hope you will not think me troublesome if I begin first by putting a question which is not answered in the notes so plainly as I could wish. The expression "breaking into" (5 of note) refers, of course, to the after-growth; but has Dr. Denny known any of his seedlings, coming up with the *seed-leaves entirely green*, ever change or afterwards break into versicolor foliage during their after-growth? In reading over the notes, my first impression was that, although the seedlings came at first with entirely green leaves, they afterwards "break into colour." If this is the case in his experiments, I have, in making similar ones, never observed a case in mine. My experience in this matter is, if the cotyledons, or seed-leaves, in ever so small a part, show "splashes" of colour, the future growth goes on breaking and expanding into colour; but if these leaves are entirely green, I have not yet observed any of them change. The colour, however, is often on these first leaves so indistinct and small in quantity, that it must be carefully looked for before it can be seen.

Last year I crossed several varieties, but in the greater number of cases neglected to take note of the pollen parent, and many of the seedlings put on an appearance that I could not well understand, and I resolved this season carefully to note the particulars of each pod of seed sown. Among my crosses last year, there was a pod of seed sown from Mrs. Pollock, crossed by pollen from Excellent; only three seeds vegetated, and are now all common-looking zonals, with different degrees of depth in their zones. One of these flowered early in the season (the flower very much like Excellent in colour), and I crossed this seedling with the pollen of Mrs. Pollock and Golden Chain, and the results from the pollen of the former are five plants, and from the latter two; but in every case they are all beautifully variegated, and sending out fresh leaves correspondingly variegated; but of course they have yet but a few leaves altogether on them, and the experiment is but a limited one, but so far it goes to show that there is something in blood. I crossed this same seedling also with various others; for instance, Annie Williams and Bronze Queen, and in many cases I have got very light-coloured results, and the leaves of some are of a beautiful shade of yellow, with a slight zone of brownish colour, at present very pretty; but from these last crosses there are many entirely green in the leaves, and my experience is that these last will never break into any other colour, and would wish much to have Dr. Denny's experience on this subject.

There was a cross which I made last year between Eleanor (a plain-leaved geranium) and Dr. Lindley (a zoned one), and I was struck with the seedlings almost from the first: when Dr. Lindley was the pollen parent the seedlings were nearly in every case zoned; when Eleanor was the pollen parent the seedlings were almost all without, or very feebly zoned, and from that circumstance I, this season, used the pollen of the variegates which I wished impressed on the progeny, but find that there are exceptions, for this year I crossed Eleanor with the pollen of Bijon, and from that cross had four plants, all of which are common green-leaved plants without any variegation, which shows that the leaf does not always follow in the way of the pollen plant. I find that I have also two crosses from Madame Vaucher; in one case Mrs. Pollock is the pollen parent, and in the other Golden Chain; but as I have only one plant from each cross, one being entirely green, the other finely marked, goes only to prove that variegates can be perpetuated by using their pollen to ordinary green-leaved plants. The crosses with the variegates and the green-leaved variety do not appear to follow exactly the same law as the zoned and plain-leaved cross above stated, but goes rather to prove the correctness of Dr. Deuny's remark, that "the foliage seems in the offspring to resemble, in a large proportion, the more vigorous of the two parents."

As to the colour of the flower arising out of crosses, I find from my notes that two years ago I crossed Lady Rokeby with the pollen from Christine, and the result was thirty-five plants, and the colour of the flowers of about thirty of these crosses bore either a strong resemblance (not certainly the identical shade) to one or other of the parent plants, and not in one instance could I say that there was a blending of the two colours resulting in a shade of colour as if formed by the united colours of the two parents.

W.

ZONAL GERANIUMS AT THE MANCHESTER EXHIBITION.—I have read the correspondence with some interest, for I was present on the first and second days of the exhibition. I consider both parties are greatly in the wrong, and I am sure that many of your readers who know nothing by observation as to the exhibition, will agree with me, for each writer indulges in personalities, and admissions are made last which should have been made at first. Permit me, as an impartial observer and critic, to make a few observations.

First, as to your report and Mr. Wills's protest. You spoke disparagingly of his plants; he was hurt, and could not say so without having a fling at Mr. Watson. Now Mr. Wills deserved more than the rebuke you gave him, and it is to his credit that he acknowledges he deserved it. Here is the main point: *Mr. Wills did remove some of his plants*, and in his letter, which appeared on the 28th of September, he ought to have owned the fact, instead of waiting until the confession was forced from him. I should always watch a case closely which arose out of alleged errors in the Magazine reports, for it is everywhere known that, for fulness, accuracy, and interest, we never had such reports before, and we may take the reports of this particular show in evidence. You say that Mr. Wills put a lot of green-leaved plants in a group professing to be variegated. Mr. Wills tries to escape the responsibility by abusing Mr. Watson's plants, and praising his own. At last it turns out that soon after (and it matters not to the argument how soon after) the awards of the judges Mr. Wills removed the best of his plants, and put others in their place that were not variegated. He is found out by the quick eyes of your reporter, or I suppose by the Editor himself, who was one of the judges, and remained in Manchester a second day to make a report. A great fuss, certainly, and it ends so far in proving Mr. Wills to be lacking in straightforwardness. Now, as to Mr. Watson. Because he was attacked by Mr. Wills, he feels bound to return the compliment, and he does it very badly indeed. His object is simply to puff his plants into note. Just as Mr. Wills says, "Florence is without doubt one of the best tri-colors in existence," so Mr. Watson cries, "Miss Watson surpasses every other ever seen or heard of," &c., &c. Now I think Mr. Watson would never have been drawn into this indiscretion, had he not established himself in the dislike of the profession, as one of the most talkative exhibitors ever seen or heard of. I am concerned in the management of flower shows, and I have made it a rule never to send Mr. Watson a schedule, because we don't want him preaching over his plants the whole day long, to the inconvenience and annoyance of visitors, and the injury of exhibitors who do not preach and palaver. Remembering how Mr. Watson held forth at the last June show at Manchester, I can forgive Mr. Wills for falling foul of him, though the question raised had nothing to do with Mr. Watson's loquacity. If Mr. Wills exhibits again at Manchester, or anywhere else at a more than one day's show, he must leave his plants the whole time, or he must not put his name to the substitutes, or he must put up with truthful reporting. If Mr. Watson ever exhibits again, he must be as quiet and un-demonstrative as other exhibitors, or he will find that committees have agreed not to make room for him; he will be other than welcome, for people have had enough of it. He does not lecture or preach over his plants at Regent's Park, for the simple reason that he is not allowed, and in some other places I can assure him the "silent system" will be rigorously enforced. I remember, Mr. Editor, reading somewhere in one of your works a brave eulogy of gardeners as the very best of men, and a challenge to the world to declare if a gardener had ever been hanged. I beg of you to revise your thoughts on the subject, with the aid of this discussion. Mr. Wills says, "You are so and so;" Mr. Watson retorts, "You're another." It is evident that these gentlemen are not looking, as they should be, for the promised millennium.

HENRY SAGE.

[We hope there will be no more correspondence on the subject.—Ed.]

Replies to Queries.

Hays's Constant Stove.—Letters come in almost daily from correspondents who wish to purchase this admirable stove, and know not where to apply for it, the London agent having disappeared. A correspondent having been placed in a difficulty as to obtaining peat charcoal of a suitable kind for the stove, has learnt that it may be obtained of Messrs. Elsam and Co., the Peat Charcoal Company, Upper Thames Street, London. There are two qualities sold, and the prices are 30s. and 60s. per ton respectively; that at the highest price is well adapted for Hays's stove, but the cheaper article is too soft and dusty. The company will not sell less than one ton to any customer.

F. T. K.—You must fumigate your cinerarias with tobacco. There is no other way to deal with them.

Cool Orchids.—Subscriber.—Probably the best two orchids to begin with in a greenhouse would be *Epidendrum vitellinum* and *Oncidium bicallosum*. You could obtain a good plant of either for a guinea, or both for the same sum, if little bits would suffice. These would do best in pots with good peat, and good greenhouse treatment is sufficient for them. When you get used to these, you may try *Cypripedium venustum* and *insignis*, *Anguloa Clowesii*, *Dendrobium speciosum*, *Lælia majalis*, *Odontoglossum citrosum*, *Sophronites grandiflora*, and others. In the "Garden Oracle" for 1865 is a short treatise on orchid-culture, which will afford you every needful information.

Marrow Peas.—Friend may do well with such varieties as *Advancer*, three feet; *Burbidge's Eclipse*, two feet; *Stuart and Mien's Prince*, four feet; and *Lord Raglan*, four feet. You may do very well without peasticks; iron or wooden stakes, driven in firmly at about six feet apart on each side the row, and tarred string run along from stake to stake, will keep peas together well, no matter how tall they are. Of course, the height of the stakes must be regulated by the height of the peas.

Friend.—The splendid hybrid *Clematis* raised and sent out by Messrs. Jackman and Son, of Woking, are quite hardy. This would be a good time to plant them to form magnificent beds of blue and purple flowers next season. The best of the male *Aucubas* to furnish pollen is the one called *Fortune's Maculata*, *A. japonica mascula maculata*; it has fine broad leaves, richly spotted with yellow. The correct accentuation for the generic name of the toreh lily is *Tri'toma*, but the lingual organs of Englishmen persist in making it *Trito'ma*, and the wrong way is undoubtedly the easiest and most euphonious. We do not believe in strict technical accuracy in these matters, and after the debate on *Gladiolus profer* the vulgar way of putting full force on the antepenultimate.

G. Fox.—What do you mean by the "Australian acacia"? There are dozens, probably hundreds, of species and varieties of *Acacias* natives of Australia. The good useful species, such as *arnuta*, *lophantha*, *rotundifolia*, *grandis*, &c., may be obtained at any respectable nursery.

S. R.—A small boiler and a service of 3-inch hot-water pipes would be the best for your house; but two of Joyce's or one of Hays's stoves would be enough to keep frost out.

Stockton, Engineer.—Your plant is *Catanancho cerulea*.

E. S.—The flowering plant is *Polygonum Virginianum*; the small fern is the crested variety of *Pteris serrulata*; the other fern must be in fruit to be named correctly.

The Gardener's Magazine.

SATURDAY, NOVEMBER 2, 1867.

WHAT IS THE USE OF THE ROYAL HORTICULTURAL SOCIETY? We ask the question with the view of obtaining information, and not by any means for the purpose of entering upon any unkind criticism. If any of our readers can tell us what is the use of the society, or can give us any account of what it does that might not be better done without its aid or countenance, we shall be most glad to give publicity to the facts in these pages. But why ask the question, while we have in our minds a proper reply, that the society is of no use at all? Well, just for this reason: it has become the custom of late to institute special subscriptions for special purposes, which it appears to be the special prerogative of this society to carry out as part of its mission, and in justification of the large funds it gathers from its supporters. No one now contemplates the calling of a meeting or proposing an exhibition without preparing at the same time to send the hat round. An exhibition of variegated-leaved pelargoniums could not be agreed upon until there was a guarantee given that the persons intending to compete would first subscribe the needful funds for it. A subscription is now going on for a similar purpose; the society does nothing beyond offer a place for the exhibition, which secures for its coffers the contributions of non-fellows who come to see it, and strengthens its hold upon its fellows by providing them with an entertainment. The society risks nothing, and does nothing, but stands ready to receive all gains; a very ingenious mode of "improving the occasion." Now there is a feeling of anxiety prevalent amongst exhibitors as to the economy of great exhibitions, and especially of those that are continued beyond one day. There is the society assuming to itself a representative power and an administrative capacity; but it can do nothing in this matter, exhibitors must find the money and do all the society's work. The *Gardener's Chronicle* of Saturday last proposes that "the principal exhibitors and growers of plants around the metropolis, as well as the patrons of gardening in general," should "contribute a limited subscription of perhaps £5 each," to provide a suitable building for great and long-continued exhibitions. We were simple enough in our remarks on this very subject, in last week's Magazine, to suggest to the council of the society, and to the directors of the Crystal Palace, and to the promoters of great shows generally, to prepare more liberal schedules, seeing that great and long-continued exhibitions usually proved highly remunerative in a financial sense, and severely taxed the powers of exhibitors. Our contemporary knows better than we; it knows the Royal Horticultural Society to be an incapable entity, or perhaps a nonentity; and now that another subscription is proposed, we do not want any one to answer the question with which we commenced, because we feel bound to close with questions of another kind, DOES THE ROYAL HORTICULTURAL SOCIETY REALLY EXIST, AND WHEREABOUTS IS ITS HIDING PLACE?

DISTRIBUTION OF SURPLUS PLANTS FROM THE PUBLIC PARKS.—The First Commissioner of Her Majesty's Office of Works intends to have distributed this autumn, among the poorer inhabitants of London, the surplus bedding-out plants in Battersea, Hyde, the Regent's, and Victoria Parks, and in the Royal Gardens, Kew. If the clergy, school committees, and others interested will make application to the Superintendents of the Parks nearest to their respective parishes, or to the Director of the Royal Gardens, Kew, in the cases of persons residing in that neighbourhood, they will receive early intimation of the number of plants that can be allotted to each applicant, and of the time and manner of their distribution.

THE TREES IN HYDE PARK.—Some correspondence has appeared in the *Times* on the pruning of the trees in Hyde Park. It is alleged that the trees are pruned, or have lately been pruned, in a very careless fashion, large limbs being taken off in an unceremonious manner, and the trees hacked and chopped about in a way to indicate that firewood was of more importance than beautiful trees. We sincerely trust the reports that are current may prove to be founded in error. Should they prove to be true, we shall believe that Hyde Park is blessed (or cursed) with genuine jobbing gardeners of the London school, whose faith and practice is to regard trees solely as objects for mutilation or destruction; never, by any chance, as deserving of careful preservation for their beauty, shelter, and their immense influence in the purification of the atmosphere. If vegetation be sentient, London trees must suffer as many or more agonies than the calves in Smithfield Market.

No. 131, NEW SERIES.—VOL. X.

NEW YORK consumes a thousand barrels—or nearly a million—of eggs per day. They come mainly from the West.

MULBERRY TREES are being planted at the Cape of Good Hope for the purpose of silk-growing.

THE HUSKS OF THE PICKPOCKETS' HARVEST.—The gardeners employed in the Trocadero, at Paris, in arranging the flower-beds, after the removal of the wooden huts erected for the Emperor's *fête*, found forty-four portemonnaies. As is known, the omnibus station is on the Quai, and the probability is that the pickpockets having exercised their dexterity, disembarrassed themselves of these material proofs, after emptying them of their contents. In the whole forty-four only two five-franc pieces in gold were found.

AMERICAN VINES AND WINES.—The *New York Times* says there has been a remarkably bountiful grape-crop in the United States this year. The vineyards are heavy with their rich clusters, and some new and superb varieties have obtained an unexpected success. If now, from some variety of the American grape, some skilful discoverer would draw a really good, palatable, cheap light wine, he would render a service to his countrymen, and to public health, morals, and temperance, which would insure him fortune and fame.

TESTIMONIAL TO MR. EDWARD PURDON.—Some time since it was resolved to present Mr. Purdon, of the *Irish Farmers' Gazette*, with a testimonial in acknowledgment of his services as honorary secretary of the Dublin Mansion House Cattle Plague Committee. The promoters selected for the purpose Messrs. Howard's steam-engine, plough, and cultivator, with the tackle, which had been worked with such signal success at the recent cattle show of the Royal Agricultural Society of Ireland. The presentation took place on Thursday, the 31st instant; after which the apparatus was removed by rail to Kibboughram Forest, near Enniscorthy, where the Messrs. Purdon are carrying on extensive improvements, and which is now admirably suited for the working of the steam-plough, and where the public can have frequent opportunities of witnessing the operations of the steam-plough. It is agreeable to see true patriotism thus acknowledged in the sister isle; for, after all, the best friends of Ireland are they who improve her industry and enlarge her resources, while saying least about her grievances and the necessity of reforms. Mr. Purdon well deserves the compliment paid him, and we wish him both entertainment and profit of the steam-plough.

MR. WILLIAM LOVE, the chief constable of the Royal Society for the Prevention of Cruelty to Animals, died on Sunday at his residence, Nelson Villas, Avenue Road, Stoke Newington. Mr. Love had been connected with the society for about sixteen years, and was noted for the zealous performance of his duties.

THE CRANBERRY CROP.—The cranberry crop near Boston, U. S., of the present year is now about half picked, and it promises to be the largest yield ever known in that part of the country. Several meadows have reached a state of maturity, and the crops on some of them are ten times as large as last year. Everywhere in the eastern part of the State, as far as heard from, the crops are larger than any previous year, except in Warwick, where the worms have done considerable damage, and there the crop will be light. Cranberries are now selling from 4 dols. to 5 dols. per bushel, and the market is dull. The price this fall will probably range from 8 dols. to 9 dols. per barrel.

TREATMENT OF OIDIUM.—The following is from the pen of Baron Liebig: "A French landowner in the department of the Indre, whose vines were severely attacked by oidium, had asked my advice about a remedy, the sulphur being no longer of any use. I advised him to manure his vineyards with wood-ashes and phosphates. Last October he sent to me a document signed by a number of persons who had seen his vines; it declared that those which had been manured with ashes and phosphates had produced healthy fruit, while others close by, which had not received these manures, were the prey of oidium."

THE VALUE OF LATENT BUDS.—The following is from an Australian paper: A portion of a small vineyard situated on the Yarra was submerged by the floods last summer. The water remained about the vines for two days. After it went down, the young growth of stems, leaves, and fruit turned quite black, as if destroyed. The owner hit upon the expedient of cutting-in the vines, as in ordinary winter pruning, reducing the stems to three or four buds each. In a short time the pruned vines began to push a second series of shoots, healthy and vigorous, as if nothing had happened to throw them back. The bunches of fruit "set," and in due time produced an excellent crop. When frosts destroy the promise of a crop of fruit, why not practise this expedient? The hint is thrown out for the vine-grower to profit by. If the plan succeeds in the one case, why not apply it to the other?

FREEZING THE BRAIN.—The great discovery that the brain of a living animal could be frozen and afterwards could recover was made by Dr. James Arnot, who solidified the brain of a pigeon by exposing it to a freezing mixture. Here research stopped, because with an ordinary freezing mixture it was not possible to act on individual parts of the organ; but the importance of the discovery is not the less on that account. It was a marvellous revealing. Think what it was! Here was a living organ of mind, a centre of power, of all guiding power, of all volition. It took in every motion of the universe to which it was exposed. It took in light and form and colour by the eye; it took in sound by the ear; sensation and substance by the touch; odour by the nostril, and taste by the mouth; it gave out, in return or response, animal motion, expression, all else that demonstrates a living animal. With it the animal was an animal; without it the animal was turned into a mere vegetable. And this organ, the very centre and soul of the organism, was, by mere physical experiment, for a time made dead—all its powers ice-bound. And this organ again set free, received its functions back again, and, as we know now by further observation, its functions unimpaired. Surely this was the discovery of a new world.—Dr. RICHARDSON, F.R.S., in *Popular Science Review*, October.

CONCERNING ROSES NOW PROPAGATED.

The improvement that has been effected of late years in all the good points of the rose merits special remark. We have indeed passed the time of phenomena, such as the introduction of novel forms and new species; but now that we have gathered together from all quarters of the world the many races of the rose, and for some years an innumerable host of rose-raisers have been engaged in blending these diverse races in infinite variation, we are acquiring flowers which possess the highest qualities and beauties of each, and, what is more wonderful, a continuity of blooming power, which practically makes the Hybrid Perpetual easily the prince and the perfection of flowers. One grand consequence of this has been, as the celebrated Laffay some twenty years ago foresaw, that the old favourite *summer roses*, which far outshone the scanty flowering and delicate growing Hybrid Perpetuals of early dates, are now quite neglected. More recently modern Hybrid Perpetuals, produced within the past twelve years, are steadily pushing out of the market their predecessors, and even the Bourbons, the Chinas, and most of the Teas.

Take a catalogue of any of our leading nurserymen, and it is impossible not to be struck with the "conspicuous absence" of once favourite roses. Confining our observation to Hybrid Perpetuals, we find that of those raised by Laffay, Vibert, Desprez, Hardy, and others, four only of those which were *mises en commerce* up to the year 1844 remain, viz., *Duchess of Sutherland* (the earliest survivor sent out in 1839), *La Reine*, *William Jesse*, and *Baronne Prevost*; the first three being Laffay's, the last Desprez's. And of these *La Reine* and the *Baronne* only occupy a first rank; but neither the former opens well enough, nor is the latter fine enough in form for modern taste.

During the next ten years, particularly after 1847, the year of *Géant des Batailles*, an immense number of roses were introduced, of which few survive. This last-mentioned rose, a seedling of M. Guillot père, was the first high-coloured Hybrid Perpetual of merit, and consequently attracted great attention, but it is now, as compared with many rivals, quite second-rate. The other survivors of this decade are all light roses—viz., *Mrs. Rivers* (most excellent, but not free enough, and not successfully grown except in fine deep loam), *Auguste Mie*, *Caroline de Sansal*, *Comte de Nanteuil*, *William Griffiths* (excellent on dwarf brier, not on Manetti), and *Louise Odier*. Besides these, there appeared in 1853 the well-known *Gloire de Dijon*, a compound Tea, which is in all respects *hors ligne*.

And now for roses brought out between 1855 and 1867. To begin with 1855, a wonderful year, the French sent us *Jules Margottin*, *Général Jacqueminot*, *Lord Raglan* (another of Guillot's, père), *Duchess of Norfolk*, *Duchess of Orleans*, *Prince Léon*, *La Ville de St. Denis*, *Gloire de Vitry* (best on own roots), *Mesdames Domage*, *Masson*, *Jaquin*, *Cambacérés*, and *Vidot*, and lastly, *Louise Peyronney*; all useful roses, although probably not three of them are equal to the best of the same colour produced within the last five years, for exhibition purposes. These were followed by *Madame Knorr* (very lovely in the bud, but not double enough, the first striking variety of C. Verdier), *Souvenir de la Reine d'Angleterre* (very large, rather coarse, but of a wonderfully bright fresh rosy colour), and *Triomphe de l'Exposition*. Then came, in 1858, but sent out in 1859, *Anna de Driesbach* (the first striking variety of Lacharme's), *Anna Alexieff*, *Comtesse Chabriland* (Marest), *Eugène Appert* (Trouillard, the only decent production of this raiser), *Lælia* (a repetition of L. Peyronney), and *Virginale* (the best existing white, but of such weak growth and bad constitution as to make us hope that it may soon be superseded). In 1860, Guillot père sent us *Sénéateur Vaisse*, the best light crimson in existence; Lacharme, *Victor Verdier*; Fontaine, *Madame Crapelet*; Guillot fils, *Louis XIV.* (free and of first quality on its own roots, bad on every kind of stock), *Gloire de Santenay*, *Madame Boll* (too coarse, and not sufficiently perpetual); and *Madlle. Bonnaire* (Pernet, a charming white, with pink centre; habit not sufficiently robust). The following year we added *General Washington* (Granger), in some years most lovely, but not a certain rose; *Duc de Cazès* (Touvais), in some soils not first-class, but generally a very excellent dark rose; and *Madame Furtado* (C. Verdier). About this time the following good Bourbons were introduced: *Baron Gonella* (Guillot père), *Catherine Guillot* (Guillot fils), and *Comtesse Barbantannes*.

Next comes the *annus mirabilis* of 1862, from which year most of our best roses of high colours proceeded, an epoch in rose-raising. The chief are *Charles Lefebvre* (dark-scarlet, the best rose in all respects in cultivation, must be grown in all collections; this is Lacharme's production), *Duc de Rohan* (Lovequo, fine dark crimson, a noble flower if well fed), *François Lacharme* (C. Verdier, crimson, fine shape, but habit bad), *Madame Bontin* (Jamain, dark cerise, very lovely colour), *Emile Dulac* (Guillot père, beautifully cupped crimson rose, a

great favourite), *Maréchal Vuilhaut* (Lecomte, purplish red, fine shape, abundant bloomer, excellent in all respects), *Maurice Bernardin* (Granger, vermilion with a haze or flush of violet, very excellent), *Mrs. Charles Wood* (Eugène Verdier, rosy crimson, very popular), *Prince C. de Rohan* (also from E. Verdier, maroon and scarlet, the best dark rose), *Souvenir de Lady Eardly* (another of Guillot's, père, reddish scarlet, not cultivated so much as it deserves), *Souvenir de Comte Cavour*, (Margottin, crimson and dark violet, requires high cultivation and pure air, under which conditions it is exquisite), *Olivier Delhomme* (another of C. Verdier's, crimson red, very good), *Vicomte Vigier* (also from C. Verdier, approaches lake in colour, particularly towards the centre, not large, but good), *Madlle. Clémence Joigneaux* (Liabaud, bright rose, lilac-shaded, very large and good), *Beauty of Waltham* (a seedling of William Paul's, whose name in rose culture is deservedly held in honour—this rose has been said to resemble Madame Crapelet too much, but there can be no question of its distinctness, the Beauty has a squarer aspect, and a somewhat different habit of growth), and lastly, that unique and floriferous Noisette Perpetual, *Louise Darzins* (another of Lacharme's, pure white, in graceful clusters, and nicely cupped flowers).

The next year the French took a base advantage of our expectations, excited by the past year's success, and sent over sixty-nine new varieties, of which about one-tenth only have been found worth propagating. These are *Alfred de Rougemont* (Lacharme, dark purplish red, shot with bright red in centre, now surpassed); *Baronne A. de Rothschild* (also Lacharme, fiery red, one of the best); *Madame Freeman* (Guillot père, an excellent creamy white, larger than the individual flowers of Louise Darzins, the best white H.P., the footstalks not quite strong enough to bear the flower erect; but that peculiarity is shared by most of the teas, and many other roses, and has this advantage about it, that it saves the bloom from much soiling by rain or sun); *Le Rhône* (Guillot fils, scarlet, magnificent colour, no better rose for bedding); *Vainqueur de Goliath* (Pernet, brilliant mulberry red, very great bloomer, a capital rose); *Madame Alfred de Rougemont* (Lacharme (?), like Louise Darzins, but a trifle larger and centre pink); *Emotion* (Guillot père, described as a Bourbon, but very early in bloom, and very continuous, colour white, centre broadly tinted with exquisitely delicate flesh pink, good).

In addition to these, our English raisers sent out *John Hopper* (Ward, who ought to be punished for giving such a rose such a name; this most unromantic rose has no rival; it is a glorious vindication of English skill; colour rosy scarlet, shading off to lilac rose towards the outside petals; back of petals lighter and silvery); *Lord Macaulay* (sent out by W. Paul, velvety crimson, variable, sometimes plum-colour, a splendid rose); *Lord Herbert* (W. Paul, rosy carmine, reflexed shape, distinct); *Lord Clyde* (Paul and Son, scarlet crimson, effective, but hardly equal to either of the other noble lords). Since this date English florists have taken courage, and let us hope that they may yet produce a royal rose to beat Charles Lefebvre.

The year 1864 was a good year; Eugène Verdier treated us unusually well: *Madame Victor Verdier* (properly described in the catalogues as vivid carmine, large, full, magnificent in shape, intense in colour, and very fine), *Alpaide de Roturier* (transparent rose), and *Leopold Premier* (deep red, with a tinge or bloom of light violet), were three of his best, and are first-class roses. Then *Duchesse de Morny* (Guillot fils, pure rose, majestic in shape, the very best of its colour), *Pierre Notting* (Portemer, blackish red with light violet tinge, a noble-looking flower), *Leopold Hausberg* (Granger, bright carmine, excellent in colour and form), *Madame D. Douville* (Levêque, glossy rose, lined with white, unique and effective, admirable for forcing, but it does not seem so good in the open garden).

The next year we added some capital roses, of which the best are *Marie Baumann* (Baumann, superb in every way, brilliant scarlet crimson); *Duchesse de Caylus* (C. Verdier, rosy carmine, the finest as to form of this colour, not large, but first-class); *Dr. Andry* (E. Verdier, bright red flushed with crimson, perhaps the best rose at the exhibitions of new roses of that year); *Madame Amélie Halphen* (Margottin, purplish carmine, good, but rather flat in shape); *Madame Moreau* (Gonod, very lustrous dark crimson, one of the most effective roses known); *Marguerite de St. Amant* (Jamain, pink, deeper centre, the finest rose of its colour, perhaps of any light colour); *Xavier Olibo* (Lacharme, scarlet densely shaded with black, a wonderful rose); *M. Boncenne* (Liabaud, very dark crimson), and *Achille Gonod* (another of Gonod's, carmine red, very large, a little coarse, but good, and likely to become popular). Besides these, W. Paul sent out *Eliz. Vigneron* (light rosy pink, something like Lælia). Paul and Son advertised *Princess Mary* (of which the writer of these remarks hopes great things, pale rose edged glossy rose, abundant bloomer.

fascinating, and highly meritorious), and Craunston's *King's Acre*, of which any opinion, good or bad, is reserved; it must be tried a little longer.

We have now arrived, after a long critical survey, at last year's roses. Here criticism becomes dangerous, because it is quite impossible to speak with conscientious confidence of such recent importations, which have even this summer barely got over the shock of intense propagation, planting, excessive manuring, &c., and of which nobody but a few nurserymen have seen a dozen flowers of each variety. It is true that every year a well-known rosarian enlightens the public upon the dark and mysterious subject of the seedlings which *are to be sent over from France*; but such writing is to a reader "vanity and vexation of spirit," and not a whit more trustworthy than the inflated loquacity of a French catalogue. It is with diffidence and caution that the following remarks are made on last year's novelties, but after as thorough an inspection and consideration as circumstances would allow. Of French roses the best, as admitted on all hands, out of a vast collection of over seventy, are, 1. *Alfred Colomb* (Lacharino), 2. *Souvenir de Dr. Jamain* (ditto), 3. *Chas. Rouillard* (E. Vordior), 4. *Mlle. M. Dombrain*, 5. *William Rollisson*, and 6. *Jean Lambert* (all ditto); 7. *Exposition de Brie* (Granger), 8. *Josephine de Beauharnais* (Guillot fils), 9. *Mlle. Rody* (Fontaine), 10. *Comtesse de Palikao* (Pernet), 11. *Madame Billion* (Gonod), 12. *Frédéric Bihorel* (Damaizin), and 13. *Camille Bernardin* (Gautreau). But this list requires much refining down, and, executing that process, we may pretty confidently place Alfred Colomb as No. 1 in all respects; personally, I believe it to be the next best rose to Charles Lefebvre; that is the highest possible praise; I hope it will turn out its equal; colour very bright crimson; very large, noble form; of course it requires good cultivation, because of its size and fulness; if so treated, I do not think any bloom will be below the mark. Next I should place *Charles Rouillard*, light rose, darker centre, full, fine form, of a class which needs a few recruits. Next No. 7, which received a silver medal in France; scarlet-crimson, not uncommon in colour, but very massive and well-proportioned in form, and so vigorous in growth as to claim the highest favour. We must award to the *Comtesse Palikao* the next place; it is very lovely and unique, very rich pink with lighter, almost white, outside petals, so perpetually in bloom as to exceed everything else ever seen among roses, and therefore in all respects necessary to the rose garden. No. 11 is novel in colour, salmon-rose, a desirable addition. No. 9, dark rosy crimson, is very large and fine, with most splendid foliage of large leaves. No. 2 is certainly the best of the violet-shaded very dark roses; it dies off a peculiar bluish tint, and gives us some hopes of yielding, through its seedlings hereafter, Mr. Prior's "blue rose;" it may be set down as one of this year's best. The others I do not at present consider better than their forerunners in the same shades of colour, but I believe, nevertheless, that No. 8—certainly highly thought of by the raiser—ought to turn out better than *Lælia*, which it much resembles, but does not excel apparently. No. 4 has not the desired habit of growth or substance of flower to suit us. No. 5 is of peculiar colour among scarlets, but not of high quality. Of the rest opinions vary widely.

Of roses of this very year—I quite endorse the Editor's experienced criticism—the most reliable selection for amateurs is *Antoine Ducher*, dark rose (Ducher, a seedling from Madame Domage, therefore worth trying); *Charles Verdier*, fine light rose (Guillot père, from Victor Verdier); *Horace Vernet*, claret crimson (Guillot fils); *Comtesse de Jaucourt*, white, tinted rose, highly thought of in France (Céchet); *Thorin*, clear crimson, sure to be good (Lacharme); *Ville de Lyon*, dark rose, free-flowering, elegant form (Ducher); *Paul Verdier*, bright rosy crimson (C. Verdier); add to which *François Treve*, scarlet with bronze shading, good form (Liabaud); *Comtesse de Morgues*, cherry-red, the inner petals said to be sometimes edged with white, raised from Victor Verdier (Pernet). Eugène Verdier's list I do not like: for example, *Napoleon III.*, which was cracked up for the most, will not do; it is too thin and too uncertain in character; *Annie Wood* is probably his best, but there is nothing novel about it.

We have some promising English seedlings, viz., *Mrs. Ward*, a cross between Jules Margottin and Comtesse Chabriland; it ought to be better than John Hopper, which it appears to resemble in character of flower, but not quite in habit or shades of colour; this comes from Ward, who also sends out *Mrs. John Berners* and *Ipswich Gem*. W. Paul sends out *Black Prince*, dark crimson, resembling Gloire de Santenay, but quite dark; and Paul and Son have exhibited, and now advertise, *Duke of Edinburgh*, a seedling much like Exposition de Brie as exhibited, but said by them to be much brighter; this rose will be distributed in the summer. Probably at the same time *Miss Ingram*, from Turner's establishment, will be procurable; this last rose was raised by Ingram, of Frogmore,

and is a rose of great promise; it is said to be the best or second-best of the English seedlings—something between Madame Rivers and Madame Knorr at their best, very light flesh edged with white, globular, but tapering in the bud, and therefore opening well: the petals seemed thin at the shows, but that is said to be an exceptional appearance.

VIATOR.

STOCKS FOR ROSES.

Not very long ago some over-cautious person ventured to predict that, such was the growing rage for roses, the country would soon be stripped of briars. The Manetti and other stocks of course considerably relieve the demand for briars; but, without going into the question of their respective merits, the brier is at least necessary for tea-rose budding.

And I should be glad to ease the mind of the cautious gentleman alluded to, and also make brier-getting a simple thing to amateurs, and even nurserymen; for I have found many of the latter who not only were unacquainted with the method I will suggest, but actually would not believe it.

Put in the ground as thickly as you can, at this time of the year, cuttings of the ripe wood of the brier; cut out all the buds that will be covered with the soil, and next year you will have plenty of dwarf brier stocks fit for budding on.

This is no experiment; I have done it year by year; and, in proof of what I say, I may add that on brier cuttings which I put in the ground in the autumn of 1865, I budded in the summer of 1866, and have shoots of roses on them eight feet high this year, with excellent roses that have bloomed better still. Put in cuttings of robust-growing roses; you thus have rose blooms if the budded varieties fail, and need not be afraid of suckers.

These make capital dwarf-stocks for pot-roses.

I know that this is but a repetition of our Editor's advice about obtaining roses on their own roots, applied to briars, or roses as stocks for other varieties; still, as the Magazine is a Saturday paper, we may sometimes expect a *réchauffé*.

EDWARD N. POCHIN.

THE SELAGINELLA OR LYCOPODIUM.

In selecting Selaginellas, the colour has to be studied quite as much as the size of the plant, for there certainly is no beauty in a brown Lycopod of any kind. Most of the species are inhabitants of hot and humid climates, and to grow them successfully their habitats can be studied and imitated with great advantage, for all will grow with the richest luxuriance in a warm and moist atmosphere. It is not at all probable that anyone will fix a temperature especially to suit them, but they can be kept in the same house with other plants which require a temperature of 60° through the winter, and 70° through the summer.

I prefer pans for growing these plants in, for they are shallow rooting, and do not require a great depth of soil, and we are enabled to give them a much larger space to spread over than would be practicable in pots, for a twenty-inch pot is not a very handy thing to shift about. Pans of eighteen inches in diameter are a very convenient size for most kinds, such as *cæsia*, *formosa*, and others of that type; whilst for kinds like *apoda*, a smaller one is far better. The pans should have about an inch of drainage crocks broken rather fine, a layer of rough peat, and then the pan must be filled up with a compost consisting of peat, loam, leaf-mould, and silver sand, equal parts. This should be pressed firm, a layer of sand put over it, and the cuttings laid on and pegged down. The cuttings should be good-sized pieces. I take them off at the base, close to the soil, which is better than the tops, and if they are properly attended to, they will soon take root and cover the pans. It is best to keep them renewed in this way than keep a lot of old plants; for when they are old, they are bad, and get broken about, and bear no comparison to young healthy plants. I am speaking of the strong-growing kinds now. *Cæsia* can be kept in good trim by cutting it down to the pan when it becomes a bad colour, and if it has a little fine soil and sand, or sand alone sprinkled over it, and set in a warm corner, it will soon recover.

Kinds which have *inaequalifolia* and *reticulosa* for their type require a slightly different method of treatment in their propagation. Instead of laying the pieces on the top of the soil, the old plant should be taken out of the pan, divided into small pieces, and dibbed a few inches apart in fresh soil, in pans about nine inches in diameter, and as they cover the pans be shifted into larger sizes according to their requirements; they are slower growing than the others, and do not make large plants so quickly. Any time of the year will do for the propagation, but now is as good as any; for during

the winter the cuttings get nicely rooted, and in the spring grow away and make plants at once, whereas spring-struck pieces do not make plants before the end of the summer.

The great number of the fossil remains of these extremely beautiful flowerless plants which have been found in the coal measures of this country by the geologists, has given rise to the supposition that the Lycopods were far more plentiful than they now are; and some botanists hold the opinion that in the earlier ages of this world's history there existed species which attained to magnitudes equalled only by the timber-trees of our woods and forests. Though we have none in existence at the present day whose height cannot be measured most conveniently in inches, *levigata* being the only species which is endowed with an aborescent aspect, we have in the exotic species some of the loveliest gems which Dame Nature has thought fit to adorn mother earth with. Wherever a collection of stove plants is grown, or, more properly speaking, wherever there is a suitable place for growing them in, so surely ought this class of plants to be strongly represented, for they are quite at home, and thrive where it would be next to impossible to keep any other plant in a healthy growing state, even if it could be persuaded to drag out an existence, which would not be at all likely to compliment the cultivator for the skill and trouble expended upon it. My plan is to stick them amongst large specimen plants, where they can have the advantage of the shade from them, putting the Lycopods, of course, so as they can be readily seen, for it is no use to put a light under a bushel; and I find they do better amongst plants than anywhere else. They are also well suited to stand amongst strong-growing ferns, for the spreading nature of the fronds of the ferns prevents the pots being set close to each other, thus giving ample room to stand dwarf-growing plants, which require similar treatment and a deeper intensity of shade than the ferns. I do not for a moment say that it is absolutely necessary that the Lycopods should be grown under the shade of other plants, because it is not necessary; for they will grow in a house with a suitable temperature if there are no other plants of any description but them in it, provided that the house is properly shaded. My reason for suggesting the suitability of these plants for growing between others of larger size is this—the stove is generally of limited extent, so that every inch of space is required to be made available for growing something or other, and there is always space between the pots of large specimen plants, although the plants may meet overhead, suitable for growing dwarf plants like the Lycopods, thus leaving the other space, which has the advantage of the full light, available for growing other subjects which require exposure to the light, and which would otherwise be taken up with them. It may be as well for me to observe, that unless *casia* and *levigata* are grown in a deep shade, it is next to impossible to grow them to any size, and at the same time retain that beautiful deep metallic lustre which is their distinctive quality. For want of shade, too, some kinds soon get shabby and unfit for exhibition purposes.

I am aware spring is generally recommended for striking young plants; but I like to propagate them in September or October, for there is no danger of the cuttings damping off if they are carefully managed, and not kept too wet and cold. As regards water, these plants will stand almost any amount, if the pans are full of roots and the drainage perfect; but a trifle more in quantity than that required by a free growing fern suits them best. A syringing twice a day overhead will be of immense advantage in promoting vigorous growth, unless in damp weather in autumn, and through the very short days, when they are better without the syringing.

The following selection contains none but handsome free-growing kinds, which I can recommend. First we have *S. apoda*, a very small compact species. This requires great carefulness in watering, as from the closeness of its growth it is apt to go off in the centre. *S. casia*, dwarf trailing, of a deep blue colour when well grown; the pans in which it is growing require to be elevated a little to allow the branches to hang gracefully over. *S. denticulata* is a very useful dwarf kind, will grow best in a greenhouse, and makes a capital edging for conservatory borders. Then we have *S. erythropoda* (*umbrosa*), *formosa*, *inequalifolia*, and *levigata* (*casia arborea*); the last named is a grand kind, one of the best, and a very strong grower. The best way to treat this is to pot it, and train it over a trellis, the same way as a *Cissua*. I have grown them five feet high on a balloon trellis, and noble objects they are too. I have seen them fifteen feet high trained to a pillar, presenting a remarkable spectacle. It will be scarcely necessary for me to say that this *levigata* is not a suitable species to grow between other plants. The following are also desirable: *Syallii*, *Martensii*, *Martensii variegata*, *Warszewiczia*, and *vibiculosa*.

GEORGE GORDON.

IMPORTANCE OF FRUIT-TREE CULTIVATION.

By CHARLES BALTET, NURSEYMAN, TROYES.

"France is the orchard of Europe."

For many years past a considerable portion of the community have employed themselves in the cultivation of fruit-trees. The best varieties have been sought out, as well as the most robust and fruitful trees, and have been tortured into all sorts of forms under the pretence of art, or else neglected altogether under the idea that nature will nourish and sustain her children in perfection, without any trouble on the part of the cultivator.

But, in spite of frequent failures and disappointments, the followers of the art are ever ready to begin again, for horticulture gives to her devotees health and quiet hours, with joys which are always new. The adepts in the art, far from cooling or becoming indifferent to their favourite employment, are constantly inflamed by the sacred fire which burns within them, and attract by their example numbers of recruits, who press forward to swell the ranks of the tillers of the earth, and increase by their exertions the national resources.

The production of fruits has now become an important part of agriculture, and forms a considerable item of food for the maintenance of the people; and so much has the knowledge of good fruits gained ground of late years, that if one goes into the market, or enters a restaurant, William pears are demanded and Curés refused; for nowadays every one has in his own garden either a Duchesse d'Angoulême or a Doyenné d'Évier.

In spite of the regard which is always paid to new varieties, the modern fruits have been a good deal criticised, and the old fruits have been disdained with an ingratitude which has not been at all merited by the services rendered. Is it not caused in some measure by our variable temperament, which leads us like children to run after the unknown, without stopping to consider whether that which we already possess is not amply sufficient for our wants?

In pomology, as in agriculture, in the sciences, the arts, and politics, it will not do to fall violently in love with everything that is new, nor yet to be prepossessed only with things that are old; we must learn to profit by the experience of each one, and know how to discern the good and the true, in order that we may be really benefited.

Now, with regard to fruits, we do not sufficiently consider that our ancestors possessed vast properties where the trees could joyously spread out all their roots and all their branches; we read that in each enclosure—the gardens of the abbey, of the mansion, and of the castle—the construction of high walls, necessitated by other causes, served for the fruit-trees, which found in the shelter of the espalier the conditions indispensable to bring them to perfection. If we attempt to place these species in the open air, we are disappointed at the result, and raise an outcry about the degeneration of the old sorts.

Now in studying new fruits, you may be sure that, in order to discover one really meritorious individual, it will be necessary to reject ten others, in spite of the very violent predilection which the raisers have for their children. It is just the same with inventions; whence it comes that we have inferior productions pompously vaunted in terms which should describe only things which are really choice and valuable.

We possess many exquisite varieties both ancient and modern; to doubt this would be to deny the progress of our forefathers and that of our own time also. We must say also, that, following in the march of things in general, the taste of the public has become far more exacting than it used to be; but this is no matter of complaint, but rather of congratulation.

The patriarchal nourishment of bread and water appears to us nowadays like a fable—or a punishment. Our palates require choice aliments, wholesome and varied. We wish to have fruits at our meals, and between our meals; we are happy in offering them to our friends; and we consider ourselves very badly off, if we have not a single apple to eat, or so much as a pear to quench our thirst, or are compelled to pass through Lent without tasting fruit at least every Sunday.

To have fruits all the year round is our dream, our ideal, as perpetual motion is the dream of the mathematician, and a blue dahlia the ideal of the florist.

To this ardent love of good fruits we join an element which was unknown till lately, which now belongs to the poor as well as the rich, which brings the purchaser, and which carries away the merchandise; this element is the railway. With this powerful assistant, and the perfect liberty of its transactions, the crop which is not required in one place can be immediately conveyed to a district where there is a scarcity.

In matters of economy, one of the first axioms is that production should always be on a level with consumption; it may often be more, but should never be less.

Now, for contributing to this production our locality is advantageously situated. If France, a country eminently fertile, is called the orchard of Europe, we can say that the region of the east, occupied by the department of the Aube, is admirably adapted for fruit-tree cultivation.

We are in effect sheltered from the rigorous cold of the north, from the burning heat and dry winds of the south, from the salt breezes which blow from the sea-shore, and from the sudden changes of temperature which generally occur in the neighbourhood of mountain ranges, checking the normal vegetation, the fecundation of the flower, and the growth of the fruit. Then add to this happy climate the geographical position so favourable to the transportation of our wares; the proximity to the capital, the means of transport by railway, by water, or by our admirable roads, the easy access to Paris and London, as well as to Belgium and Germany.

As it is necessary to utilize that which we have, and to give a value to that which at present has none, we ask that the untilled lands, the uncultivated hills, the neglected pastures, and the dried-up marshes, be converted into orchards. France has, it is said, six millions of hectares of untilled land. Our department would be greatly favoured if it contained none; but unhappily it possesses too large a share. It is, however, certain that this state of things will soon undergo a considerable change. Thanks to the generous initiative of the Prefect of the Aube, M. Isidore Salles, and with the benevolent concurrence of the Council-General, a public and gratuitous school of arboriculture has been instituted in this country. Thus, after having received the lessons from the professors appointed to carry on this mission, several corporations have planted their denuded mountains, and their arid plains with fruit-trees, and the results which have followed are highly gratifying.

Encouraged by these first results, several other departments hastened to imitate us, and the plaudits of the agricultural and horticultural press. But, above all, the populace comprehend the benefits conferred upon them by

the culture of fruit-trees; they listen to the professors, they read the authors, and plantations intelligently conducted are the consequence. The consumer is benefited and the producer is enriched.

In order to prove to you that the subject I am treating is worthy your consideration, I will now mention divers localities which have made considerable incomes by the sale of their fruits.

The department of Yonne has, with that of Somme, several corporations much richer than their neighbours, entirely through the culture of the cherry. At Saint-Bris (Yonne), a hundred hectares of untilled land have been converted into cherry orchards. The only variety grown is the Royal English Early grafted upon Sainte-Lucie; they are grown in bushes, are not pruned, and can be reached without ladders. The Parisian and English brokers come in the month of June, when the fruit is in maturity, to purchase the crops. In 1863, the sale of cherries had risen to 80,000 francs, and in 1864 to 100,000 francs.

The mountains of Pny-de-Dôme produce the most beautiful apples, and the apricots grown there are the most celebrated for apricot-jam. These two kinds of fruits form a considerable object of commerce to the district.

Near Paris, where speculative culture is well understood, they have transformed the sandy hillocks which extend from Trilou to Meulan into apricot orchards, which are very celebrated among the confectioners of the capital.

The valley of Hÿères, in Provence, formerly much reputed for its oranges, now contains many enclosures of peaches. Last year the fruit sent from this part to Marseilles realized the important sum of 160,000 francs.

At the present time a little village of Haute-Marne has in its woods fruits which realize 9,000 francs per annum without costing them a penny for their maintenance.

The corporation of Balzac, near to Angoulême, has sold in one season its pears and cherries for 30,000 francs.

Near Agen, there are several growers, who sell for 10,000 francs the plums of a single crop. Near Meaux, there exists a pear-tree of an ordinary variety, but very productive, which produces, taking good years with bad, 150 francs' worth of fruit. Near Brie-Comte-Robert they have cultivated pears for fifty years, and their crops produce at least 100,000 francs.

Touraine and Anjou are certainly highly favoured by the sun, climate, and position. I will mention, for example, the department of Maine-et-Loire, one of the finest divisions, in order that you may understand how very important the cultivation of fruits is to the country. In less than a year this department has exported to Paris five millions of kilogrammes of apples, representing a value of 500,000 francs. Angers alone has received during one day 40,000 kilogrammes of apples, and 10,000 kilogrammes of pears. The price of transport received by the railways and boats is not less extraordinary.

The choicest varieties of pears, such as William, Bonne Louise d'Avranches, Duchesse d'Angoulême, Beurré Diel, Beurré d'Hardenpont, Doyenné d'Hiver, are sent in large quantities to Havre, from whence they are taken by the large steamers to London or St. Petersburg.

It is scarcely credible that this locality of which we are speaking has sold to the Parisians during two months 785,226 kilogrammes of cauliflowers, and 300,000 kilogrammes of dandelions, which realized a sum of nearly 200,000 francs to the sellers, and 100,000 francs to the growers in the neighbourhood of Orleans. The benefit to the community is all the more clear in this instance, because the dandelions are gathered by very poor families in the fields and meadows and from the neglected lands in the neighbourhood of the slate quarries.

I have mentioned the best varieties of eating pears, but which of them can dispute for a moment the palm of beauty with Belle-Angevine? A celebrated restaurant-keeper of Paris has undertaken to purchase all we can grow of this superb variety, to satisfy a passing taste of the day. However, let us not be dazzled by such a thing as this; let us not abandon these exquisite varieties, although at the same time we take care to satisfy the caprices of the world. Bergamot Espéren, Reinette true, and Mirabelle, can never be surpassed in their way, nor can the pear Van Marum, the apple Ménagère, and the plum Dame Aubert.

The cultivation of grapes for the table is also very lucrative. At Pouilly, in Nièvre, the manufacture of wine has given place to the sale of Chasselas and Muscatel grapes for the table; the vine-dressers have become thereby fifty per cent. richer, and the sum-total of the sale has amounted to a million and a half of francs. In our own neighbourhood, Bar-sur-Aube, they used to make an ordinary white wine of Chasselas grapes, but they find it more advantageous to send the fruit to the markets of the great towns. The village of Baroville bassold to the Parisians 50,000 francs' worth of Reine-Claude in a single year. Perhaps it would be far better for those vine-growers who think of giving up entirely the cultivation of the grape, to devote their attention to the culture of grapes for table instead of for wine.

A merchant goes to Gard every year to purchase the crop of Chasselas grapes for which he pays the proprietor in advance about 10,000 francs, and his brother merchants buy for large sums the Chasselas of Montauban. One cannot talk about Chasselas without thinking of Thomery, for it is there that it is grown in the greatest perfection; all the inhabitants are employed in its culture, and are enriched by it.

Montreuil is equally celebrated for its peaches; every family has its plantation of Galande, Mignonne, or Madeleine; and when we consider that this fortune is due in a great measure to chance, what should we not be able to attain to in places so eminently suited to cultivation?

Already at Beaune, the soil or the heat has made the Chasselas of a rosy colour, velvety, and very enticing. The Société d'Horticulture has sent a delegation to Thomery in order to study the treatment of the vine, and has offered prizes to the planters.

It is certain that these undertakings profit the world at large as well as the growers themselves, and it is thus that the more favoured south is able to lend its sunshine to the people of the north. The vine-growers of Bourgogne or of Beaujolais plant peaches in their vineyards, and in the same manner the Algerians preserve in the gorges of Laghouat oases of plums, and the mountaineers are enabled to supply the absence of corn by living upon chestnuts. We may mention on this subject that the corporation of Morvan, Saint-Prix, sells annually 60,000 francs' worth of chestnuts.

How many communities are there who might find in analogous employments to these the resources which now fail them! And it is worthy of notice that the poorest places are the poorest where the waste lands are the most numerous; yet, what are these waste lands but treasures which former generations have transmitted to us, and which no one has yet dared to touch? We have already in our department some hardy pioneers who have ventured to plant the flag of progress; let us encourage them by our plaudits, and they will attract numerous imitators.

In other regions also they have found these innovators. The journals

have vaunted the philanthropy of a priest at Ain, who causes the plantation of a fruit-tree at the baptism of each new-born child; and of another in Lorraine, who has formed a nursery on the mountains of fruit-trees, which are generously distributed among his parishioners, and thus gives ease and assist-ance to the common poor.

I have nothing to say about the cider fruits of Normandy, Bretagne, Picardy—in fine, of the countries which rebel from the vine; it is a fundamental source of riches which is well known. In a word, the price of apples is already doubled, by reason of the exportation to Manchester of fruit which is gathered while green, before the juice has been transformed into sugar, because they employ them for fixing their colour in their stuffs.

Will not the financial question awaken the attention of cultivators who are so disposed to groan in this agricultural crisis? To all the preceding facts I will finally add that the reputation of the prunes of Agen and Sainte-Catherine (Tours) has certainly enriched the producers; and we could name at the same time the Mirabelle plums of Metz, the gooseberries of Bar-le-Duc, the strawberries of Dijon, the figs of Argenteuil, the nuts of Isère, &c.

Entire provinces are quickly metamorphosed by contact with a product niggardly and mean in appearance, a fruit or a herb. This modification will soon operate by the initiative of men of action, thanks to the development of modern horticulture and the multiplication of railroads. These last have already revolutionized commerce and industry; and agriculture and horticulture cannot long remain indifferent.

And when we ask that speculation shall be attracted to fruit-trees, we do not pretend to hinder or straiten the culture of cereals, of vines, and of woods. That which we solicit is that the lands condemned for sterility by the carelessness of man be cleared, and that useless plantations be replaced by orchards, fruit gardens, vines, and even kitchen gardens; the annual revenue of economic vegetables of the first necessity in nutrition or in industry offers advantages which will not suffer by comparison.

In the category of sites badly occupied, permit me to place equally with the others those strips of land along the sides of roads which are at present occupied by woods. Why not clear them, and have them planted with our favourite species, which would certainly pay a thousand times better than the others? Why, it is objected to this plan that travellers along the roads would gather the fruit; so much the better, we would do good to our neighbours. Do you prefer to plant elms, ash-trees, or sycamores, to be preyed upon by cantharides and may-bugs? If you are afraid of exciting marauding, leave the ornamental trees in the neighbourhood of towns, and only plant the fruit-trees at a distance from them, and then if the crops are gathered and sold early, there will not be much loss from theft. Besides, the farmer to whom these plantations are let will be interested in the protection of his fruits. I have seen this plan carried out in Alsace by the agents of the roads, and every year they clear thus several thousands of francs.

The borders of rivers and canals would gain equally by being subjected to a similar régime; and the neighbourhood of water would favour the production of the subjects planted upon their banks.

And the railways? Would not their receipts be considerably augmented by having fruit-trees grouped upon their slopes, their borders, and their unoccupied waste plots? The companies have certainly no reason to fear the depredations of their passengers.

Now, with regard to that which relates to the species to be planted, their culture and preservation, we would not leave the planter to lose his way in the labyrinth of arboriculture and pomology. In an ornamental garden, we may allow ourselves to try forms both new and strange, and to glory in collecting an indefinite number of varieties at the risk of being disappointed afterwards if they do not equal our expectations. But here it would be foolish to throw our capital into the venture unless there was a fair prospect of getting it returned with interest. What we want is a limited number of robust and productive varieties which have been proved to be excellent; these we may plant in thousands, as they must be treated in the most simple manner; for it would be wrong to have any complicated system of culture, the expense of which would reduce our benefits and cripple our means.

You see, then, that the subject is vast, and should be studied under all its aspects; in my opinion, it is a mine of gold.

Let us, then, be the apostles of progress; let us demonstrate both by our words and actions that the cultivation of fruits is a public benefit and an important assistance to the sustenance of the nation, too often, alas, frustrated by the bad and unwholesome samples which are foisted upon our markets.

The day when we shall have transformed a denuded arid site into a plentiful and fruitful orchard we shall have performed a good action. I cannot help remarking, that the cultivation of flowers and fruit is far more moral than speculating in the money market; for it gives to man riches and happiness, the love of his paternal roof, of his family, and of his work, and gains for him the respect of himself, and of all who know him.

If I insist so much upon this question, it is because I have studied it much; I place it far above a money consideration, for I see in it a question of high civilization.

THE HEDGEHOG IN THE FAMILY.—The graphic pen of Mr. Frank Buckland, in *Land and Water*, recapitulates the following reasons against introducing hedgehogs into the bosom of one's family as auxiliaries against beetles and cockroaches:—"I have tried hedgehogs to kill beetles. They don't act. A hedgehog cannot possibly hold above a pint of beetles at a time, and in my kitchen there are gallons of them. I once tried the hedgehog plan at the Deanery, Westminster. The first night after his arrival the Abbey watchman was frightened out of his wits; it was the hedgehog. The next night, fast asleep, I felt a cold nose on my face, and then a prickly thing trying to get into the bed; it was the hedgehog. The next night the servants came trembling to say there was a burglar in the dining-room rattling the plate; it was the hedgehog. The next night the cook put some soup away, and in the morning the soup was gone; the hedgehog was found coiled up asleep in the tureen. The next night nothing was heard of the hedgehog, and for weeks we could not tell where he was gone; the cook was thankful, and the crickets sang, O be joyful, while the blackbeetles had free run of the kitchen. 'Years rolled on,' as the novelists have it, and a skeleton was discovered in the flue, which had smoked the whole of the house out for weeks. The hedgehog again. Thank goodness, I have seen the last of that wretch, and never wish to have another of his kind on the premises. Unless, therefore, my friends wish to run the chance of a hedgehog becoming the same pest to them as he was to me, they will never introduce them into their houses. Hedgehogs will only eat a certain number of beetles, and the beetles, having good spawning ground behind the kitchen range, breed much faster than the hedgehog can eat."

THE FLOWERS OF PARIS.

Flowers have the rare privilege of being loved by all—by the rich as well as by the poor, by the civilized as well as by the savage. It is not only in the midst of plenty that people conceive the idea of embellishing their dwellings with flowers. Their cultivation on a large scale among the French peasantry and by the poorer classes of great cities, has perhaps contributed more to the civilizing of the coarser organs than all the treatises of philosophy ever penned. Those who have studied French life in its different phases can testify that a honeysuckle around the door of a cottage, or a jessamine on a window-sill, are always good omens to a tired traveller. For my part, I know of a professional beggar in Paris who only tunes his harp and sings before those houses on whose balconies ivy, nasturtium, or sweet pea are struggling for existence, well aware that the hand which cultivates plants can never be closed against the supplications of the poor. At one of the windows of the house in which I live are a few geraniums, a fuchsia, and a rose. I always notice that it is before this window that those who have obtained a license to beg congregate, very certain that from the flower-pots will fall something to their advantage.

Fortunately, however, flowers do not attract the attention of beggars alone. Many are the great men and women of France who have held these floral apostles in reverence; many have been the consolations derived by kings and queens from their twined petals and perfumed breath. Louis XIV. specially loved the scent of the orange blossom, and had one huge tree in every room of his palace. Mdlle. de la Vallière, wishing to conceal her state, surrounded herself with tuberoses, the scent of which, although peculiarly agreeable to the grand Roi, was considered as fatal to women in her situation. Marie Antoinette was passionately fond of flowers, and constantly wore natural ones on her court dresses. On the morning of the day on which she was to receive, for the first time, the Emperor and Empress of Russia, travelling under the name of the Comte and Comtesse du Nord, the Queen desired her tirewoman to bring the dress she was to wear into her houbdoir, and wreath it with fresh flowers according to her own directions. The woman was thus employed when Louis XVI. and one of his ministers entered. The King looked surprised, as his visit had been announced. "You will pardon this breach of etiquette," explained the Queen, "but the flowers are natural, and would fade if not arranged at once." The flowers she loved so well conveyed to her the last pleasurable sensation she experienced in life. When immured in the dark and damp dungeon still to be seen at the Conciergerie, Madame Richard, the wife of the *concierger* of the prison, brought her daily a bouquet of the flowers she had always preferred—pinks, tuberoses, and, above all, her favourite julinnes. For this innocent act was Madame Richard denounced to the revolutionary tribunal and imprisoned. In later years another, who likewise occupied a throne, and was also hurled from her high estate to reap the bitter fruits of humiliation, devoted her latter days of solitude to the cultivation of flowers. Empress Josephine's gardens at Malmaison were the wonder of her time. With the aid of her gardener, Dupont, she collected every variety of rose then known in Belgium, Holland, and England, and even succeeded in raising many new species, still in high repute in the horticultural world.

The lily and violet have played an important rôle in the history of France. Under the Bourbon dynasty, the great actress Mdlle. Mars was hissed and insulted because she appeared on the stage with a bouquet of violets, that flower having been selected by the First Emperor as his emblem. The circumstance was the cause of several duels being fought. In France at present the rose is the favourite flower. I believe but one woman ever lived who hated the very sight of that blossom, and still more its perfume, and that woman was Anne of Austria. At the present moment roses are the fashion, and specially sought for by lovers and *fiancés*. In winter, as well as in summer, four hundred pounds worth of roses are sold in Paris alone, which makes 4,320,000 roses in the year. As it is the custom in France only to give white roses to young girls, even throughout the winter, the gardeners of the environs have invented a special system of forcing by which this flower can be produced at any time of the year. Rose-trees are placed under frames at a heat of 20° Réaumur for thirty to forty days, during which time the plant, whatever be the original colour of its blossoms, produces white roses. To alter the colour of the plant this heat is gradually increased, and every ray of light excluded from the frame during the last days previous to the opening of the flowers. The white lilac plants and bouquets, sold at so high a price in the streets of Paris during winter, are produced in this manner. Many are the purchasers of white lilac plants who, having carefully preserved them during the winter, have planted them out in their gardens in the spring, and been amazed to see their delicate white blossoms reproduced in the coarser kind of the common tree lilac. This fact very nearly caused the rupture of a long engagement between two young friends of mine, which engagement had, however, stood the test of time and much opposition. On last New Year's Day the young *fiancée* received from her lover a beautiful plant of white lilac, covered with delicate blossoms and pale sea-green leaves. I am not learned in the language of flowers, but I am instructed by one less ignorant than myself that white lilac signifies constancy, and I know not how many other equally valuable attributes. It was a parting gift. Victor de M—— was to start the following morning for Algeria, to join his regiment of Spahis quartered at Blidah. Lucille well-nigh killed the plant with care, for the *fiancé* was to return in spring and claim her for his bride; her whole heart was set, therefore, on its reflowering then. Truly the poor lilac recovered marvellously, when planted out in the open ground, from the evil effects of spending a winter in the heated atmosphere of a drawing-room, and grew and put forth leaves; but lo! they were a horrid dark green, and blossoms came of a vulgar lilac such as one gathers in the hedgerows. The very next day after this discovery Victor de M—— returned; and, horror! his first inquiry was for the white lilac, for he had attached a superstitious interest to its reflowering. Lucille vainly tried to turn his thoughts to another subject, but he persisted, and at last, with a beating heart, she led him to the sunny spot in the garden where it was flourishing, and at that moment a mass of lilac flowers.

"But that's not the plant I gave you."

"*Mais si*, I have taken such care of it."

"That is not my plant; that has been given to you by some one else—by your cousin, perhaps, in the Garde Impériale, that Alphonse, as you call him, who was always hanging about, and, now I think of it, bringing you flowers besides."

In vain his betrothed assured him that it was the very plant he had given her on that last day when she had shed his bitter tears. She admitted the transformation was strange—inexplicable; but she had prayed so much to the blessed Virgin, maybe it was a special mark of her favour—a miracle, in fact.

"*Supristi!* Miracle, indeed! Cousin Alphonse, in the Garde Impériale,

was the miracle, and it was for his sake, or for the sake of his uniform, she had watered it, and wept over it, and prayed to the Virgin over it, and—

and—"

A thought struck poor Lucille at this crisis. "You remember where you purchased the plant?" Certainly he remembered—at Montreuil, and it had taken him half a day to get there; and he might have saved himself that journey and another beside it.

"Will you return there," sobbingly asked his *fiancée*, "and relate what has occurred, for my sake?"

Not he. He wouldn't go to Montreuil with such a *coq-à-l'âne* story. The case was plain. He would return to his regiment, and never think of woman again. They were all alike for that matter, as his father had often told him, and his colonel, and all his comrades—only he had thought Lucille was different.

It is easy to get into a rage and storm away, but is not always quite so easy to act up to what one has said in the white-heat of jealousy. The ride from Ville d'Avray to Paris was long, and M. le Lieutenant had scarcely cantered down the avenue of my friend's chateau before he repented his hasty words. The thought occurred to him he might as well turn his horse's head towards Versailles and dine at Duboux, and, perhaps, in the evening, he would take Montreuil on his way home. True, it would be fourteen miles! What cared he for fatigue? Life was all one to him now. He had come from Algeria—and, by the bye, given up the chance of a lion hunt with Pertuiset—all for the sake of the veriest coquette that ever breathed; but he ought to have thought of it before. That Alphonse was always at Ville d'Avray, and besides, his regiment of La Garde had been quartered at Versailles that winter. So convenient a lounge too! just ten minutes by rail. However, for the curiosity of the thing, and just to clear his conscience, he would go to Montreuil, and never mind the dinner at Duboux. And to Montreuil he rode, and at a slapping pace too, very much as if he cared to get there.

On reaching the gate of the nursery garden his heart beat somewhat quick. "Was Monsieur Bertin in the gardens?" Monsieur was engaged—he was making up a *bouquet de mariage*, for which he was selecting the flowers. "Monsieur le Lieutenant would find him at the white lilac frames."

"Ravi de revoir, monsieur," exclaimed old Bertin, on again seeing his excellent customer. "I am making up the wedding bouquet of the great heiress who is to marry Capitaine—"

"Hang the bouquet," thought Victor de M——, as he ruthlessly interrupted his loquacious friend by a succinct narrative of what was said to have occurred to his last purchase, adding that naturally he did not believe in any such transformation.

"Pardon, M. le Lieutenant, rien de plus simple. This is my forcing house. There are three hundred lilacs; their blossoms, as you see, are white—their leaves pale green. Next spring I plant them out; they become common lilacs, or rather return to what they originally were. Here is my system."

"Merci!" cried Victor de M——, "I am rather in a hurry, as I have to get back to Ville d'Avray before dusk;" and so saying he dashed out of the garden, much to the amazement of my quiet old friend Bertin, and to the discomfort of an officer in the uniform of La Garde, against whom he knocked as he tried to rush out of the narrow gate.

As he raised his *kepi* and attempted to apologize, he recognized the identical cousin Alphonse he had so much belied.

"So you have returned from Algeria. I invite you to my wedding tomorrow. I marry Mdlle. Bonnefonds, the millionaire," said the latter, after a hurried recognition.

"Ah, I congratulate you," responded Victor, as he jumped on his horse. One month later I received my *billet de faire part* for the marriage of M. le Lieutenant Victor de M—— and the fair Lucille; and as the bride swept past me in the aisle of the cathedral church of St. Louis, at Versailles, a delicious fragrance of white lilac perfumed the air, and I remarked that her bridal robes were profusely adorned with that graceful flower.

One of the glories of the Great Exhibition of 1867 is having produced a new rose, which has been called after a lovely American girl, Clémence Raoux, and was raised by Monsieur Granger, of Suisses, who has excited the envy of all the horticulturists of Paris, and their indignation besides, as he sold the sixty plants he had raised to Mr. Lee for the sum of fifty pounds.

The nursery gardens of Paris are well worthy the attention of the visitor. The most interesting, however, is that belonging to the city, known by the name of the Fleuriste de la Muette, situated at the Passy gate, in the Bois de Boulogne. This vast horticultural laboratory contains above forty hot-houses, some of which are of colossal proportions. There are few roses cultivated here, for the simple reason that their flowers are invariably robbed during the night by lovers anxious to win a smile from their various lady-loves by the offering of a rose. It required at least three *sergents-de-ville* in each square, and several more in such open gardens as the Champs Elysées and the Parc Monceaux, to defend the roses. This being considered a somewhat superfluous duty by M. le Préfet de Police, who required his men for different work, roses are but sparingly bestowed on the inhabitants of Paris. In the establishment in question, which is one of the most extensive in Europe and the largest in France, fuchsias, camas, pelargoniums, verbenas, calceolarias, ageratum, and chrysanthemums are chiefly cultivated. Three thousand frames shelter the young plants from the changes and chances of this variable climate, and immense subterranean chambers, lighted and heated by gas, preserve the bulbous plants during the winter. One immense hot-house is devoted to the rearing of the palm trees so successfully planted out during the summer months, four to camellia trees, and several to solanums, caladiums, begonias, hibiscus, musa gigantea, wigandia, &c. One hundred gardeners alone are occupied in the task of multiplying these plants, whose number this year amounted to 3,000,000. The City Nursery Gardens possess 350 varieties of fuchsias, represented by 100,000 plants. Of pelargoniums there are 200,000 plants, of which 15,000 are of the kind so popular in England called Mrs. Pollock. I saw but one specimen of the Lucy Grove, which single specimen is taken as much care of as though it were a delicate young duchess. Of the palm tribe, these gardens possess 400 different species, and have 20,000 trees at this moment scattered over the various public gardens of the capital, where, thanks to the immense care bestowed on them, they thrive, as will be remembered by those who visited the Parc Monceaux this summer. Several thousand are likewise employed to decorate the Imperial residences, and more especially the apartments of the Empress, who much admires their graceful form. The anorphi, with which the Tuileries Palace is decorated on *fête* nights, are here cultivated on a large scale; and I was informed by the Chef Multiplieur, who accompanied me through the gardens, that for a ball no less than 60,000 of these flowers were forwarded to the palace. Of camellias I was shown 1,400 varieties. One greenhouse is filled with plants in a state of convalescence, struggling back to life and health after a season of dissipation, sufferers from their many up-

appearances at Court balls, State dinners to sovereigns at the Hôtel de Ville, soirées at Princess Mathilde's, and all public entertainments; and, poor camellias! they had a hard life of it this year, what with the Emperor of Russia, the Sultan, and all the rest of the royalties—they had scarcely a night of fresh air, and indeed their appearance tells of gas-lighted corridors and stifling saloons. Another greenhouse is occupied by camellia trees kept in reserve, from which blossoms are cut and fastened on any bare branch of the trees intended for the decoration of one of these Court or Ministerial fêtes. Of these four have historic interest. Each measures from 20 to 25 feet in height. These, with two others, were sent to France in the year 1814, as gifts from Emperor Francis to his daughter Empress Marie Louise, and were then considered as Imperial gifts of no slight value, each plant then valuing £120. Two alone have died. The four that remain are in splendid health, and are at this moment covered with buds. Empress Eugénie's apartments, at whatever palace she may occupy, are supplied with fresh plants to the number of 80 or 100 twice every week. When her Majesty is in Paris, it is the duty of the chief city gardener to see to this. He personally superintends the selection of the plants, which are conveyed to the Tuileries in a covered spring cart. Her bouquets are sent daily.

On entering the fern houses I was struck by the subdued light which was produced without the aid of blinds. I remarked that all these houses had a white appearance on the glass as of a substance smeared over it. On inquiry I learnt that this shade was favourable to the growth of weak plants, and was obtained by a composition of *blanc d'Espagne* and *colle de poisson*—whiting and isinglass—which once applied with a brush cannot be washed off by rain or snow. Ferns and plants whose chief beauty consists in their foliage are now more the fashion in Paris than mere flowering shrubs, as they are considered more decorative. Ferns are therefore specially cultivated, and being the tenderest fosterings of nature, it is no wonder they are tended with so much care and attention. The grand object of every French gardener is not only to shelter them from the direct rays of the burning sun, but to produce for their benefit that moist and still atmosphere which prevails in tropical climes. Some of these festooning the brauches and trunks of trees sent from Australia on account of the rare ferns attached to their bark are of extreme delicacy of structure, and I could not help admiring the wiry drapery of their verdant fronds. Much struck was I also with the specimens of the lycopodium, sending out their runners or creeping stems in all directions, to the length of many yards, and which strike deep in the turf below, taking root there, and thus multiplying the plant *ad infinitum*, and without the intervention of the talented Chef Multiplicateur, to whose intelligence and kind consideration I owe these details, which I trust may have afforded my readers a few moments' interest.

What strikes one most in the treatment adopted by French gardeners is that their shrubs and fruit trees seem to be cut and shaped, and follow a fashion, as do our coats and waistcoats. Of this, for instance, you have a proof in the laying out of some of the Paris squares, and more especially in the fantastic forms given to the yew trees and hedges which skirt the alleys and terraces of the Parc of Versailles, the stiff formality of which is eminently suggestive of the stately and dignified manners of the Court of the Grand Monarque. Even the twining graceful ivy, trained screen-wise against the railings of the palaces in Paris, is trained to grow in even undulations. The artificial and somewhat stiff regularity with which the geraniums, fuchsias, &c., are planted, in admirable contrast as to colour it is true, leads one to fancy that the system of training adopted for the school-boys of France is now being applied to French flowers. The latter, it must be allowed, appear to prosper marvellously well under this system of imperial discipline.—*Evening Star*.

A PLEA FOR SMALL BIRDS.

As the subject of preserving our small birds to the destruction of wire-worms, caterpillars, aphides, and other destroyers of our crops, &c., is now broached by the Rev. F. O. Morris and others, perhaps you will allow me to say a few words on their, the small birds', behalf. First, then, by all and any means, preserve our songsters, but let us advocate and do it in all sincerity. Will the Rev. F. O. Morris cease to write books on birds, and so help to prevent the wholesale slaughter of rare and other birds as well as talk about it? This may seem rather hard on the venerable author of "British Birds," but it is a fact, and I do not think the Rev. F. O. Morris will deny it, that this and other works on birds has been the cause of death (indirectly of course) of thousands and thousands of our rare and singing birds, by so-called admirers of birds—collectors they certainly are, but not admirers. Have not the books on birds given an impetuosity to collecting? Have they not described their habits, their "nests and eggs," and when and how to find them? and so opened the way, or, at least, one way, to the destruction instead of protection of the birds he, the Rev. F. O. Morris now appears, and, I really believe, wishes to save from further harm? I would not wish collectors wholly to give up collecting; but I would wish them not to kill every rare bird they come across, whether they have it already in their collections or not. There are, no doubt, many rare birds killed because collectors in general are a most unbelieving set, and who, were I to-day to see (not kill) a rare bird, and were to send a notice of the observations up to the *Ibis*, the *Zoologist*, the *Naturalist*, or any other of our journals on natural history, would reply to such a notice, and say (perhaps not plainly) it was a lie, a mistake, or something, and would refuse to believe in the said rarity's occurrence, unless the bird could be produced for identification. I do not for one moment say or think the Rev. F. O. Morris is one of those men, because he records the seeing only of several rare birds in his history. Another cause of every rare bird being killed that ventures on our free (free?) land is the great price ornithologists—no, I had better say collectors, and then the real ornithologist will not quarrel with me—give for specimens. Let collectors give up collecting and take to observing, or, if they must collect, let them be satisfied with one or two specimens of each species. I remember a gentleman well—at least he was an undergraduate in our university—who killed nearly every nightingale in the neighbourhood, and indeed every other bird he could get at; so much so, that he was nicknamed the bloody-minded undergraduate—he was a collector! This is no romance; there are many who will well remember the circumstance. There is another case for which collectors are answerable. They give large prices for rare birds, and thus give gamekeepers and others a reason for killing them. Let them cease to do that, in fact, give up buying rarities altogether; but no, they will say the charm of collecting would then be gone, as we care only or mostly for rarities. What is to be done when northern men shoot all the dippers they can to exchange for nightingales with a south, south-eastern, or south-western man, who kills all the nightingales to exchange *vice versa*, and as long as there are men who write bird books, and such men

as the above-named undergraduate to read them, and to supply material for such books? I can say thus much to bear out what I say, that this self-same undergraduate receives honourable mention in the "History of British Birds!"

And then there are the "bird-fanciers." How many thousands of our song-birds are caught, caged, stifled, starved, or otherwise doomed to die every year by them, I could not attempt to say. Statistics have been published, and it is something enormous. I will hunt it up and send you if wished. Nightingales, whose eyes are burnt out to make them sing—a fact!—hucknaps, garden warblers, whitethroats, &c., no sooner arrive here, "all to welcome back bright May," than the bird-catchers are alert, hundreds are caught, of which two-thirds at least pine and die, who had they been let alone would—

Praise Him for gladness, and rejoice
With Him to lift on lusty voice
Hosannas to the light

in our woods, fields, and hedge-rows. Who that really loves our singing birds—singing as they only do sing when in the woods and fields—or that has heard the lark, the songster of joy and hope, who pours out his song of love in the fresh dew of glittering morning, as he rises higher and higher, trilling out his thanks as though his heart would burst with its very fullness, seeming but a mere speck in the glorious heavens above, and at last disappearing from our sight, and then "Hark! the lark at heaven's gate sings"—a "voice from the heavens," shedding its blessing o'er all the earth!—I once saw one shot, as it was rising and singing, by a something dressed in man's clothes—who, I say, that has heard and felt this could keep one of those very birds shut up in a miserable cage—oh yes, some have very fine cages; but a goal is a goal, even though they do give you an easy-chair to sit in—and call the wailing heart-broken apology for a song he then sighs out singing? No, I hold and believe, he or she that cages up a throatsle, skylark, or any other of our singing-birds, does not do so for love of the bird or its song, but simply to please their own vanity of possession. And now comes the farmer and his men who—hut let the Rev. W. Barnes say it in his Dorset dialect—

Last night the merry farmers' sons,
From biggest down to least, min,
G'ed in the work of all their guns,
An' had their sparrow feast, min.

Vor heads o' sparrows they've a shot,
They'll have a prize in cwein, miu,
That is, if they cau make their scot,
Or else they pay a fine, min.

We'll zend abroad our verry hail
Till ev'ry foe(?)'s a bled, lads,
An' though the rogues mid all turn tail,
We'll quickly show their heads, lads.

In corn, or out in open ground,
In bush, or up in tree, lads,
If we dou't kill 'em, I'll be bound
We'll makee their vearthers vlee, lads.

Do you think he would forgive me if I add a couple of verses to his, and say?—

An' when the sparrows all a-gone,
We "mit" as well be gone too,
For palmer-worms and grubbs will eat
Our barley, wheat, and whoats too.
An' that's not all, vor we've a killed
Our friends! the sparrows, God sent,
T'do eat up wireworms, and grubbs,
An' palmer-worms, that God sent.

Zo, lubberheaded clothopper,
Go poison, shoot, and prove O,
Destroy all sparrows, greenfinches,
An' linnets, do not snare O;
An' at your sparrow clubs and veasts,
You stupid vools and pigs O,
He who shows most sparrows' heads
Will show the longest ears O.

And last, though not least, comes the almost every owner of a gun, be he gentle or simple. Who does not remember *Punch's* twin pictures—the aristocratic pigeon-shooter on one side, and the—please, Mr. Editor, find me a name for him—gull or any other bird shooter, on the other. Laugh! No, did you laugh? Because if you did you made a mistake. Everything in *Punch* is not meant to laugh at. Some things go too deep for that. But I will leave *Punch*—he can take care of himself. I wish our small birds were as able.

Only two or three Sundays since I was walking with a friend "in lanes with flowers sweet," when, "bang!" and out of an adjoining field rushed three or four boys; one had an old rusty gun, but one which was evidently doing its murderous work, as another of the boys held a long string of small birds, tied by their necks, among which were whitethroats, skylarks, black-birds, &c., and I am extra sorry to say a robin. These boys certainly had no fear of broken arms or legs, which I was taught to believe every one who killed a robin or took a robin's nest would be sure to get as the necessary consequence. And then there is Christmas-day, Good Friday—bad Friday it should be, so far as the birds are concerned—Easter Monday, and any other holiday that may turn up, with their hundreds of shooters. And there is my lord and the great moneyed man: is there a mansion or hall in the country but what has its cases of rare and other stuffed birds?

Who is to blame? I should say that individual everywhere to be met with—Self; for if Self would but think and do unto others as he would be done unto, we should have no more complaints of the scarcity of birds, be it of song or not. And I fear "self" ranges from the very top to the bottom of mankind. The peer, or wealthy man, who shoots for fashion, pleases self; the naturalist and writer on natural history, who collect and write for vanity, please self; the snob who shoots for fun, or the lout who poisons his best friends rather than let them have a few grains of corn or a cherry—all, all is self. Let the wealthy man shoot birds only that are worth being shot for food; the naturalist study the habits, ways, and manners of birds, and he will find more to write about than measuring wings, legs, and bills, or counting the feathers in the tail, and the grumbling at his fellow naturalist because his measurements and countings do not agree with his own, till they get to very much the same as the Robins in Professor Kingsley's "Water Babies," where, in a dispute over a worm, one said that it was his worm, and that, if it was not, then it was not a worm at all! And lastly, let the farmer or his man open the crops of some of the birds he has poisoned, shot, or trapped; let him look the contents well over, and count the number of insects and weed-seeds against the number of grains of corn he will find there, and he will become an anti-bird killer forthwith.—CANTAB, in the "Standard."

Calendar.

WORK FOR WEEK COMMENCING NOVEMBER 2.

Kitchen Garden and Frame Ground.

ASPARAGUS AND SEAKALE for the first supply to be put in at once. All that is wanted is a mild sweet bottom-heat. A melon bed still retaining some warmth may be revived by turning it over, and mixing with the dung a good proportion of leaves, straw, grass-mowings, and other fermentable litter. A bottom-heat of from 50° to 60° will be ample. Place the roots close together, and cover with light soil. Seakale must be shut up close and dark; asparagus will want air and light; the latter to be cut when the plump purple crowns are two or three inches long above ground.

PEAS AND BEANS.—Sow at a risk First Crop and Saugster's No. 1, and Mazagan beans. In low situations, where snails and slugs abound, there is little chance of success. On high and dry positions they will probably endure the winter, and come in earlier than spring-sown crops. Aspect is not of so much importance as dryness. Raised borders under walls facing south are generally chosen for these sowings; but an exposed position, if dry, will be nearly as safe. The usual causes of failure are damp and vermin.

SLUGS AND SNAILS are now very active during mild weather, preparing perhaps to make a good fill before hibernating for the winter. It happens that most people have time now to trap them, which they generally say they have not at other seasons. Brewers' grains or buttered cabbage-leaves are the best traps known for these destructive vermin. They will leave any other food for these attractive baits, and may be trapped wholesale by inverting large flower-pots tilted off the ground by means of a few sticks over heaps of fresh brewers' grains.

Flower Garden.

ROSES planted now, though with leaves still on them, will begin to make fresh roots at once. In any case make the ground ready by manuring liberally where roses are to be planted. Briers worked this season may be lifted now, but they should never have a place in the rosery till they have made at least one full season's growth from the first starting of the buds. Plant firm, and stake at once.

SPRING FLOWERS to be thought of now, so as to secure a proper succession of Cyclamen, Primula, Cineraria, and a few potted Pansies. The chief point in managing these things is to keep them as near the glass as possible. Give water very carefully, to guard against damp at the collar, and let them have as much air as possible consistent with their forwardness and the state of the weather. Those to be pushed on for a first supply keep in warm greenhouse temperature, and constantly look out for fly, which will revel amongst them if not checked in time.

AURICULAS.—Damp is now their great enemy, and yet water must be given, if they want it, at the root. Keep the glass over them, and give air liberally. Remove dead leaves, and guard against drip.

DAHLIAS.—Take up at once, or as soon as the frost has spoilt their beauty. A few dahlias, which we took up on clean stems by disbudbing rather late in the season, are now nice standards in pots, and will make a show under glass for some time to come. This may be a useful hint to those who have heavy demands upon them to keep conservatories gay.

TULIPS to be planted at once. Lord Mayor's Day is the commencement of the season among the fanciers; if planted earlier, they break ground too soon in the frost; if later, they flower weakly. But bedding tulips may be planted any time from the 1st of October to the middle of November.

ROSE STOCKS to be planted at once. Reject all the grey hard-barked briers; the best are those with formidable spines and a greenish bark. Plant roses for blooming next season. A stiff well-manured soil suits them best, and, except in very cold districts, the more open the position the better.

GNASS TURF.—This is the best time in the whole year to lay down turf. Secure for garden lawns turf of fine quality and close growth, containing a good proportion of clover. Generally speaking, the best turf is obtained from commons where it has been continually eaten close. The ground must be firm on which the turf is laid, or it will sink in places during the winter. When laid, let it be well beaten and the joints closed.

HOLLYHOCKS of choice kinds should be taken up and potted, and a few of the shortest shoots taken from each and put round the sides of pots as cuttings; they will root without the aid of heat in a frame or pit.

CARNATIONS AND PICOTÉES to be kept comparatively dry, and very freely aired. Prepare the compost for next season's potting by chopping over two parts yellow loam with plenty of fibre in it, one part rotten cow-dung, and a half part of fine siftings from old plaster or road-sand. Lay this up in a ridge, and let it be several times turned during the winter, especially with a view to get the whole mass two or three times frozen through.

LOBELIA CARDINALIS and its kindred should be taken up and planted in boxes to keep over winter in frames, or separate the shoots and pot the offsets separately, or four or five together, in 48-sized pots.

A MIXED BED OF HARDY PLANTS.—As alterations and improvements are now in progress, we introduce here descriptions of a few good beds consisting entirely of hardy plants. This, the first bed, is a circle twelve feet in diameter. It is raised above the general level, so as to present a gentle convexity of the same degree as an ordinary watch-glass. In the centre is a fine pampas grass, *Acyroium argenteum*. At a distance of three feet from the pampas grass all round there are clumps of the gorgeous *Tritoma uvaria*, the fiery flowers of which shoot up through the fountain-like leaves of the pampas, and have a most magnificent appearance. Between the clumps of tritoma are tufts of the rather new and splendid grass, *Arioso conspicua*, which has been flowering most gaily since the middle of June. This is quite green all the winter, and always beautiful. It does not grow so tall as the pampas, and is more robust in appearance. Between these grasses and the margin are clumps of *Spiraea filipendula*, which cannot be surpassed for grace and beauty; *Statice latifolia*, a very bold and handsome plant; *Aspidistra lucida variegata*, which is quite hardy, and has all the splendour of a choice variegated toxe-plant; *Punkia Sieboldii variegata*, a most beautiful plant in both leaf and flower. The margin is furnished with tufts of small grasses, such as *Festuca ovina glauca*, *Dactylis glomerata variegata*, *Stipa pennata*, and *Eragrostis elegans*. There are spaces between the several plants, and during the summer these spaces are filled up with French marigolds.

BED OF SAXIFRAGES AND HOUSELECKS.—This bed is to be seen in the centre of the herbaceous garden in the grounds of the Royal Botanic Society, Regent's Park. This also is a circular bed, raised above the level by a

gentle swell. It is divided from the centre into compartments, each compartment being, of course, of a wedge shape, the apex at the centre, and the base forming part of the boundary of the bed. The bed measures about fifteen feet across—it is likely to be a foot or so more in width rather than anything less. The compartments are eight in number—four of them consisting wholly of saxifrages, and four of sempervivums; the effect is most remarkable, simple, yet grand; and, in the early part of the summer, a vast sheet of flowers beautifully harmonized, at all other seasons luxurious in the most elegant leafage; a masterpiece of effect with only eight sorts of hardy plants. The saxifrages are, *S. hypnoides*, *S. pulchella*, *S. oppositifolia*, and *airoides*. The first-named has swelled up into huge pillow tufts of the brightest emerald green, looking like a bed for a weary man to recline upon and forget his troubles; the other sorts are rich, without a break, and most luxuriant in growth. The sempervivums, or houselecks, are *S. hirtum*, *S. Californicum*, *S. montanum*, and *S. arachnoides*, all of a fine growth, and producing myriads of red flowers. When Mr. W. Robinson had the care of the herbaceous garden there, we have stood with him on a sunny day in June, and seen the flowers of *S. hirtum* as thickly covered with bees as the great sheet of vegetation was thickly covered with flowers; and we have agreed that, for an inexpensive and interesting sort of gardening, there could be nothing to surpass such a bed as that, as it only needs to be made of sandy loam, and planted with tufts of the proper plants a foot or so apart, and then will take care of itself, and continually improve in appearance during any ordinary lifetime. And it has this advantage, that on a small scale it is equally effective; the reason it is on a large scale there is that the place is large, and the herbaceous garden contains many things that have no beauty, and this bed is a sort of compensation to reward for their trouble of seeking it those who might feel disappointment with a collection formed for botanical purposes only.

A BED FOR THE DRAWING-ROOM WINDOWS.—The bed we now describe is in a garden on the north side of London, where it forms a distinct and beautiful feature. It is a great circle raised above the level; the diameter is twenty-four feet, and the elevation above the general level varies from eighteen to twenty-four inches, the ground being a slope where the bed is situated, but the bed itself forms a dead level. The centre consists of a mass of *Rhododendrons* eighteen feet across, which leaves a margin of three feet all round. This margin is planted with a ring of *Cabbage Roses* close in front of the rhododendrons, and outside the roses is a ring of the beautiful *Cotoneaster Simmonsi*, and the spring-flowering *Deutzia gracilis*, which is generally grown in England as a greenhouse plant. It is one of the prettiest spring-flowering shrubs we have, and is easily forced, but it is quite hardy; the plants in the outside band alternate, a *Deutzia*, next a *Cotoneaster*, next a *Deutzia*, and so on all round. The bed is kept up on the margin by a wall of large burrs, such as rockworks are mostly made of in the gardens near London; but very little of this is seen, for over it hangs a continuous sheet of the noble German ivy, *Hedera Requeriana*, which is one of the finest of all plants for the purpose, and makes a pleasant change from the common Irish ivy, *Hedera canariensis*, which we see everywhere. Amongst the rhododendrons are many very choice kinds, such as the *variegated-leaved* variety of *R. ponticum*, a most beautiful shrub; also the very early-flowering *R. dauricum*, which is dotted with little rosy flowers from February to April, and a few always appear in November and December. Also *R. hirsutum* and *R. ferrugineum*, very choice small-leaved sorts, with such hybrids as *Jacksoni*, *Hendersoni*, the *Queen*, *Roseum*, *Alarm*, and others equally splendid, when in flower. One of the very best is *Maculatum nigrum*, which is grandly spotted. There are also some plants of *Kalmia rubra*, a small-leaved sort, with violet red flowers; and *Erica Mediterranea*, and the elegant *Ruscus aculeatus* or "Alexandrian laurel." Thus, the great centre-piece is rich and varied, and from February to June there are flowers to be seen—the principal display being in the month of May. Just at that time the *Deutzias* near the outside zone of ivy begin to flower, and their snowy blossoms look most chaste and beautiful. When they are declining, the cabbage roses flower, and their delicate colours are enhanced by the fine deep green background of the rhododendrons. At the same time the cotoneasters flower, but they make little show until all the flowers are past, and then they display abundance of their orange red berries, which last through the winter. This particular bed is the more pleasing because every one of the plants has been raised on the spot, and are the results of various experiments in propagating. The cotoneasters were all raised from berries; and I saw in the garden several large batches of seedlings of the same plant, which is raised in quantities every year. How many a garden needs such a bed as this, and how easily it might be made, with a judicious outlay in the first instance! There is wanted a good position, next a platform of good loam, high enough to allow of cutting down on the outside to a regular ring, which is to be finished with large stones or burrs. In the centre there must be two feet depth of rhododendron soil, such as sandy loam, rich in vegetable fibre, or peat well chopped up with about a third part of the most silky-textured hazel loam added. The planting is a simple affair enough, and that accomplished, there is nothing more to do.

GARDEN PLANTS IN FLOWER.—*Aster Nova Zelandica*, *A. dracemoides*, *A. conchus*, *A. concolor*, *A. Sikimensis*, *A. latus*, *A. salicifolius*, *A. grandiflorus*, *Caltha sagittata*, *Sideritis spinosa*, *Aconitum autumnalis*, *Artemisia pontica*, *Armeria vulgaris coccinea*, *Artemisia lactiflora*, *A. cernuoscens*, *Baccharia dioscoroides*, *Barbarea praecox*, *Bidens procea*, *Cineraria auriculata*, *Solidago levigata*, *S. recurvata*, *S. glomerata*, *S. tenuifolia*, *S. graminifolia*, *Pyrola media*, *Liatris elegans*, *Lobelia glandulosa*, violets, primroses, and a few auriculas flower during mild weather.

Fruit Garden and Orchard House.

FRUIT GARDEN.—Prune and plant as weather permits. Give special attention to wall fruit, and where standards have got crowded thin out the heads, but be very cautious about cutting large boughs off healthy bearing trees. Bush fruits should be pruned, and the ground forked over between the rows. Burn the prunings and strew the ashes over the newly-forked surface. Red and white currants must be cut back to skeletons; the chief of the fruit-buds being at the junction of the new wood with that of last year, leave only three or four joints beyond that point, and cut clear away at the base every branch that is ill placed, or that chokes up the centre. Black currants do not like the knife. Trim the branches to regular distances, and shorten the longest back to good joints, but preserve plenty of young wood, leaving the plumpest branches nearly their full length and cutting all weak ones clean away. Treat gooseberries in the same way; they never bear well if severely pruned. Scrub old apple-trees that are infested with blight with a strong brine, rather warm, and stop the holes with a mixture of clay, sulphur, soot, and cow-dung, beaten together into a tenacious paste. Put stakes to everything fresh planted, or, better still, three lengths of tarred rope fastened to posts driven firmly in the ground. Plantations to be

made ready for planting without delay. Let the earth be deeply stirred. Stubborn clays are greatly improved for planting fruit-trees by digging in plenty of broken oyster-shells, half-inch bones, and building rubbish from which all large bricks and stones have been removed. Of course drainage is the first requisite of success.

WALL TREES to be pruned, and as much good wood as possible laid in.

Greenhouse and Conservatory.

PERLARGONIUMS have been pretty free from disasters hitherto, but the season of mildew is upon us. Use fire-heat by day only during frost and damp; train and stop; water sparingly; do not wet the foliage.

SCARLET SALVIAS may be kept in bloom a considerable length of time in a warm light place in the conservatory, especially if rather pot-bound, and kept in vigour with manure-water.

VIOLETS potted now, by taking up strong runners, will bloom early and be of service. Use plenty of charred rubbish to lighten the compost, which should be rich.

AZALEAS.—Keep cool, or they may start too soon; a few may be started very gently for the first bloom.

CAMELIAS are now in fine bloom in many places, and only need moderate protection to keep them gay; but, as they are not yet wanted, those showing colour must be retarded as much as possible to keep them back till the chrysanthemums are over.

CHRYSANTHEMUMS to have plenty of water, and no more liquid manure. By keeping the backward plants out to the latest moment which it is safe to do so, they will come in usefully as a succession to keep the conservatory gay till after Christmas.

FUCHSIAS done blooming to be left out as long as possible to harden the wood, and those for specimens next year to be started gently as soon as they have shaken off their leaves, preparatory to repotting in a month's time. Standards must be kept slightly on the move all winter to make sure of them. Fuchsias stored under stages had better not be pruned, except just the points of the longest shoots, as it causes them to break before they are wanted. Late-struck plants will be in nice bloom now for the conservatory, and cuttings may now be put in for early plants.

GERANIUMS potted from the borders to be pruned in, but not severely—sufficient only to remove the soft sappy growth, as severe pruning would cause them to grow again too quickly. Those for special purposes and for early bloom should be cut in close and put in bottom-heat for a month. If any remain out, get them up before they melt into a jelly, and give them a warm berth for a week or two, to enable them to get hold of the new stuff in which they are potted. Poor sandy stuff for all bedders that are merely to be kept, as the less growth the better.

SUCCULENT PLANTS must now be arranged in their winter quarters. In a mixed collection the best place for them is a top shelf in the full light, and where they are not likely to suffer by drip. The requirements for their winter safety are a dry position, plenty of light, air when needful, and security from frost. Give them no water from this date, or at most water with caution only such as obviously need it; and any in active growth or flower keep warm until they go to rest.

GREENHOUSE PLANTS IN BLOOM.—*Acacia corymbosa*, *A. lophantha*, *Cytisus Atleana*, *C. racemosus*, *Coronilla glauca*, *Correa pulchella*, *Tropæolum Lobbianum*, *T. Ball of Fire*, *T. Lilly Schmidt*, *Lambertia rosea*, *Salvia fulgens*, *Chimonanthus fragrans*, *C. sinense*, *Jasminum nudiflorum*, *Globulea hispida*, *Escheveria retusa*, *Citriobatus multiflorus*, *Myoporum pumiliifolium*, *Euphrasia nivalis*, *E. purpurascens*, *E. miniata*, *Tree Violets*, *Tree Carnations*, *Camellias*.—*Ericas*: *Distans*, *Gracilis*, *Autumnalis*, *Templeana*, *Pilularis*, *Leana*, *Cubica*, *Acuminata*, *Princeps*, *Solandriano*, *Rubens*, *Viridiflora*, *Aitoniana*, *Caffra*, *Muscoides*, *Verticillata*, *Banksia*, *Cruenta*, *Droseroides*, *Rupestris*, *Taxifolia*, *Aspera*, *Pulchella*, *Hyemalis*, *Florida*, *Ralliformis*, *Niellii*, *Syndriana*, *McNabiana*, *Glandulosa*, *Lambertiana*, *Easonii*.

Stove and Orchid House.

ORCHID HOUSE.—All orchids requiring rest now should have less water and a cooler and drier atmosphere, and a more liberal ventilation, than in the growing season. Evergreen kinds will require a moderately warm position. It is at this time of year that rot and spot begin their havoc in the orchid house. Both these maladies are the result of improper treatment by the cultivator, one cause of both diseases being the continuance of too high a temperature with much moisture during the period when the plants ought to be at rest, and another frequent cause is too much damp when the temperature is low. The drip from the glass falling on the pseudo-bulbs frequently causes rot, and whenever rot appears the parts affected should be cut clean away, and the parts filled up with sulphur. Discolouration of the pseudo-bulbs is one of the indications of approaching rotteness. Spot appears to result frequently from cold draughts passing through the house when there is much vapour and the plants are damp. Removal to a drier and warmer air will generally stop its ravages; but as soon as the growing season returns the plants that were affected should be started in a brisk heat, and have every possible encouragement to grow, and they will generally grow out of it. In preparing for the winter wash all the glass and woodwork of the house.

ORCHIDS IN FLOWER.—*Cypripedium Farriaeum*, *Lælia superbiens*, *Odonoglossum Uro Skinneri*, *Sophrontes grandiflora*, *Læliopsis Domingensis*, *Stanhopea oculata*, *Cattleya maxima*, *Barkeria Skinneri*, *Lycaste Deppii*, *Dendrobium discolor*, *D. veratrifolium*, *Angrecum bilobum*, *A. sesquipedale*, *Phalænopsis amabilis longifolia*, *P. rotundifolia*, *Oncidium reflexum*, *Denbromium moniliforme*, *D. majus*, *Calanthe Veitchii*, *Oncidium Forbesii*, *Lælia albida superba*, *Grammatophyllum speciosum*, *G. Ellisii*, *Dendrobium Lowii*, *Goodyera discolor*, *G. Domini*, *G. pubescens*, *Miltonia Karwinski*, *Sophrontes cernua*, *S. violacea*.

Forcing Pit.

FORCING to be commenced now, and in accordance with hints already given preparatory to it. First clean the glass, to make sure of the utmost possible amount of light; then get together the fermenting materials—leaves and sweet dung chiefly, and over this lay six inches of tan or spent hops to plunge the pots in. Put in nothing but what has been prepared for the work, and has ripe wood and well-formed flower-buds. Azaleas, Camellias, Gardenias, Roses, hybrid Rhododendrons, double Plums and Peaches, double Cherry, Weigelia, Tree Pæonies, Chimonanthus fragrans, Rhododendron ciliatum, Cytisus Atleana, Kalnia, *Andromeda floribunda*, Daphnes, and *Jasminum nudiflorum* are all cheap and easy subjects to force, and all beautiful in their season. It requires more skill and a good stove to manage *Poinsettia pulcherrima*, *Euphorbia Jacquiniflora*, *Achimenes*, and *Gloxinias* nicely, but these may be forced in dung-heat where there is plenty of room, plenty of material, and some experience at command for the purpose.

VINES breaking to have air cautiously, as a chill may result in disease of some kind hereafter. If red-spider appears on vines planted inside, give the roots a liberal watering, in addition to the other means of eradication; a vigorous growth will prove as powerful a preventive as any special applications of Gishurst, &c. Where grapes are still hanging keep the atmosphere dry.

Correspondence.

SCARCITY OF BIRDS.—In reply to your correspondent, the Rev. F. O. Morris (p. 423), I have to report that the scarcity of such birds as blackbirds, thrushes, and starlings, has been the subject of many remarks during the past summer. Those who have known the spot from which I write (the lower part of Somerset) for the last thirty years, say they never knew so few, and they attribute the scarcity to the severity of last winter. Few places are more surrounded with woods than is the mansion here, yet I have not seen more than one blackbird during the last two months. I have seen here during the summer a large bird of unusual beauty, visiting the walks in the kitchen-garden frequently, apparently searching for the little red ants. It was not of a tame character. The prevailing colours of the feathers appeared to be brown, red, and green; and when disturbed, it started up with a shrill bold note. In Surrey I have heard them called "Yaffols." I should be obliged if your correspondent can furnish me with the name of this bird. J. C. CLARKE.

[This letter has been kept back a fortnight in the hope that we might be able to discover the proper name of the bird Mr. Clarke refers to. But we have not succeeded, and therefore join him in asking of our readers what is a "Yaffol"?—ED.]

SEA-SIDE PLANTING.—I am in difficulties about what to plant in the way of shrubs and trees, for the sea-breeze has killed many things that I planted last winter. Our garden is situated about three-quarters of a mile from the sea-shore in Lancashire. Could you recommend any kind of shrubs that would be likely to stand the climate? I find that the salt wind kills the American Thuas, likewise the Chinese, Irish, and English yews, and the common lilac. It is a very stormy situation, and we have but very little shelter from the west, and none from the north and east. We want something very hardy. If you could name a few things that would be likely to live, I should feel greatly obliged, as my employer does not mind spending money if we can get things to live. G. G.

[Can any of our friends living near the coast assist G. G.? Some practical information on this subject would be of great value to many of our readers. The following are usually considered safe subjects to plant in windy places near the sea: *Tamarix Gallica*, *Quercus ilex*, *Arbutus unedo*, *Lycostera formosa*, *Abutilon vitifolium*, *Ribes sanguinea*, common Juniper, *Pinus austriaca*, *pinaster*, and *strobis*, *Abies excelsa*. Amongst humbler subjects, the following are admirably adapted for the purpose: *Hydrangeas* of all kinds, *Fuchsia virgata*, *Atriplex halimus*, *Cineraria maritima*, and *Helleborus niger*. In such a position true sea-side plants, such as *Eryugium maritimum*, &c., should be made the most of.]

A CORRESPONDENT desires to know the address of Mr. Henry Baker, the agent for Hays's Patent Stoves. Address, G. B., care of the publisher, GARDENER'S MAGAZINE, 11, Ave Maria Lane, London. E.C.

PLUM RAISED FROM THE STONE OF A PEACH.—By the kind permission of an old cottager, I have been permitted to send you a sample of plums he has been successful enough to raise from the stone of a peach. The fruits that I have sent you are from a tree standing at the end of his cottage, north-east aspect. I am sorry to say they are not quite ripe; but I hope you will be able to inform me, through your GARDENER'S MAGAZINE, if they are new or not. I thought myself I had not seen anything like them before. I must here inform you it will not be any advantage to me, but, as the old man has asked me to look at them, and I could not think of anything to equal them, and as a constant reader of the Magazine, I thought I would send a sample to have your opinion of them through the same.

WILLIAM DALE, Gardener to T. Townsend, Knockholt, Kent.

[The plums sent were in colour, texture, and flavour, very like the Belgian Purple, and therefore quite second-rate in quality. There must be some mistake about their origin. The old cottager no doubt believes he raised the tree from a peach-stone, but there is, physiologically, too wide a difference between peaches and plums for one to give rise, by means of a seed, to the other.]

A QUERY ON THE EXHIBITION OF BOUQUETS.—At our last show, August 27th, a gentleman amateur, who was known to be from home, sent his plants, &c., to the show, and, amongst other things, a bouquet. An objection was raised that, as he was from home, the bouquet could not be his making, and it was admitted that it was not, but that his house-keeper made it from flowers gathered from his garden. It was contended that it was immaterial where the flowers came from, so long as the exhibitor made the bouquet, inasmuch as the prizes were awarded for the arrangement, and not for the quality of the flowers. I stated the question to the judges, and they decided the bouquet could not be shown. Was that decision correct? and, in fact, is it not a law well understood by exhibitors, and judges as well, that where prizes are offered for bouquets or designs in flowers, it is to the arrangement in the one case, and the design in the other, that the prize is awarded, and that it is not necessary, unless so provided by the rules, that the flowers should have been grown by the exhibitor; but it is necessary that the exhibitor should be the designer in all cases? W. G.

[The judges were too precise; yet, in strict interpretation of rules, they were right, provided the bouquet was shown in the name of a person then away from home, and who it was known had not made it.]

IT'S AN ILL WIND, &c.—Fontenelle had a great liking for asparagus, and preferred it dressed with oil. One day a certain *bon-vivant* abbé came unexpectedly to dinner. The abbé was very fond of asparagus also, but liked his dressed with butter. Fontenelle affirmed that for a friend there was no sacrifice of which he did not feel himself capable, and that half the dish of asparagus he ordered for himself should be done with butter. Whilst they were talking, waiting for dinner, the poor abbé falls suddenly down in a fit of apoplexy. Upon which Fontenelle instantly springs up, scampers down to the kitchen with agility, and cries out to his cook, "The whole with oil! The whole with oil, as at first!"

CATALOGUES.

JAMES VEITCH AND SONS, KING'S ROAD, CHelsea. *Catalogue of Hardy Trees, American Plants, &c.*—This is a fine list of coniferous, deciduous, and cistaceous trees and shrubs. Amongst the novelties and specialities we notice *Retinospora plumosa* and *pilifera*, *Cryptomeria elegans*, *Pseudo-larix Kämpferi*, the Golden larch, *Castanea chrysophylla*, *Griselinia littoralis*, &c. There are in their several places large lists of *Berberis*, *Hedera*, *Quercus*, and other genera interesting to collectors.

T. S. WARE, HALE-FARM NURSERIES, TOTTENHAM. *Catalogue of Trees, Shrubs, Roses, Herbaceous and Alpine Plants, &c.*—We have several times referred to the extensive collections of herbaceous plants at the Hale-Farm Nurseries. This neatly printed list represents the nursery fairly, and we are glad to see in it a host of good things that lovers of hardy plants will consider themselves fortunate to obtain.

J. R. TANTON, EPSOM NURSERY, EPSOM, SURREY. *Descriptive Catalogue of Select Roses.*—A capital short list, comprising all the good established varieties. It is a curious circumstance that neither general nor particular prices are given. This is a mistake; many persons will order things if they know what will be the cost, but will not take the trouble to make inquiries about prices.—*Catalogue of Imported Dutch Bulbs.* A short but very comprehensive list.

HOOPER AND CO., CENTRAL AVENUE, COVENT GARDEN. *Autumn Catalogue of Flowering Bulbs.*—A copious and interesting list, the value of which is greatly enhanced by the numerous admirably executed engravings of new and interesting plants.

PAUL AND SON, THE "OLD" NURSERIES, CHESHUNT, HERTS. *Rose Catalogue for 1867-68.*—To praise this would be waste of words, but it may be proper to say that the new roses of 1867 are classed and described separately, and the best varieties of the past season are pointed out with care and impartiality.

WILLIAM ROLLISSON AND SONS, Tooting, London, S. *Catalogue of Dutch and other Bulbs.*—This contains, in addition to the usual selections of bulbs, lists of new Japanese plants, new tender and hardy plants of special value and importance, lists of roses, grape-vines, &c.

GEORGE GIBBS AND CO., 25, DOWN STREET, PICCADILLY. *Catalogue of Dutch Bulbs.*—Messrs. Gibbs have named, amongst bedding tulips, *La Candeur*, *Rex Rubrorum*, *Tournesol*, and *Yellow Prince*, as the best four for bedding, having proved this by their extensive trial of bedding tulips in Hyde Park, in the spring of the present year, when these four kinds were all in bloom together and produced a most telling effect.

T. PIERPOINT, WARRINGTON. *Autumn Catalogue of Dutch Bulbs, Gladioli, Roses, Fruit-trees, &c., 1867-68.*—This is quite a model in respect of the amount of information given, without puffing, and with a view solely to bring before the public the best subjects in the several classes. The lists of fruits are admirably prepared.

Replies to Queries.

Marsh Plants.—J. Westcott.—The pampas does not answer on wet land in this country; it grows well in summer, but is too likely to die in winter. The following are good marsh and water plants: *Botomus umbellatus*, *Caltha palustris*, *Calla palustris*, *Acorus gramineus*, *Arundo donax*, *Cyperus longus*, *Epilobium angustifolium*, *Lythrum salicaria*. The "Garden Oracle" for 1868 will contain carefully prepared lists of such things. The query about books we do not quite understand. Thompson's "Gardener's Assistant" is one of the best books on gardening generally.

Variiegated Geraniums.—J. H. W., Manchester.—In the Magazine of the 20th of April last (page 170) appeared an article on the cultivation of Tricolors, from the pen of Mr. F. Smith, of Dulwich. You could not have a better guide. The sorts likely to be most in demand next season are—of Henderson's, *Lucy Grieve*, *Sophia Dumaresque*, and *Caroline Longfield*; of Smith's, *Louisa Smith*, *Defiance*, *Jetty Lacy*, *Souvenir de Sir Joseph Paxton*; of Wills's, *Her Majesty*, *Beauty of Ribblesdale*; of Saltmarsh's, *Meteor*. You would do well to consult the Magazine of July 27 and August 17 last. The issue of the "Garden Oracle," now preparing, for 1868 will contain carefully prepared lists of the best in every class. One of the best books to expend your money on is Thompson's "Gardener's Assistant."

Country Gardener.—The offices of the City Soap Company are in Milton Street, London, E.C.

H. Camell.—Your boxful of fuchsia flowers came to hand without any intimation of the sender, and your note respecting it arrived after last week's Magazine was printed. We have never seen a finer lot of single fuchsia blooms, and of gigantic size, leathery substance, and gorgeous colours have anything to do with relative merit, the varieties here represented are of great value, and must displace many of the very best in cultivation. Some of the flowers spread over a space three inches in diameter, and yet are symmetrical, finely proportioned, and as finely finished as they are huge in size. There is but one white flower in the lot, a very delicate thing, with waxy or crystalline sepals. This is small and peculiar, but will no doubt prove a gem in the class it belongs to.

J. W., St. Albans.—We think it best for all parties that the subject should drop.

Mr. Charles Quince, Florist, Gravesend.—It is a strange thing that we should find two ivy-leaves between two cards, and nothing more. Did you forget to enclose the ipomea, or has it vanished on the road? We should have replied earlier, but could make nothing of it.

Friend.—Any of the varieties of male *Aucubas* will serve to furnish pollen for your old trees. One male will supply pollen enough to fertilize twenty or fifty plants, if the business is conducted with care. The best male to buy for the purpose is the one called *A. Japonica mascula naeuclata*.

Novice.—Your edging plant is the well known variegated *Alyssum*.
